THURSDAY (11th).—BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Mr. Bowreman Jessett will show: (1) Carcinoma Uteri, with Dermoid Cyst of Ovary, removed by Vaginal Hysterectomy; (2) Myomata Uteri, removed by Pan-hysterectomy; (3) Hæmato-Salpinx with large Hæmatocele; (4) Tubal Gestation. The President's Inaugural Address. Dr. Macnaughton Jones: Demonstration of Specimens and Instruments from Berlin.

FRIDAY (12th).—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. J. E. Lane: Two Cases of Gastro-enterostomy.—Mr. W. Edmunds: Sequel to previously recorded cases of Excision of Malignant Growth from the large Intestine.—Mr. S. Paget: Cases of Voracious Hunger and Thirst after Injury or Disease of the Brain.—Dr. E. W. Goodall: Two Cases of Enteric Fever fatal during the third and fifth week respectively in which there was no Intestinal Ulceration.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (8th).—ROYAL COLLEGE OF SURGEONS.—5 P.M. Prof. D'Arcy Power: Intussusception.

TUESDAY (9th).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Dr. D. Grant: The Diagnosis and Treatment of Nerve Deafness.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Beevor: Lecture.

ROYAL INSTITUTION.—3 P.M. Prof. A. D. Waller: Animal Electricity.

WEDNESDAY (10th).—ROYAL COLLEGE OF SURGEONS.—5 P.M. Prof. D'Arcy Power: Intussusception.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Bidwell: Operations on the Stomach.

HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Dr. S. Martin: Cases Illustrating Points of Interest in Mitral Stenosis.

THURSDAY (11th).—SOCIETY OF ARTS.—8 P.M. Prof. J. A. Ewing: The Mechanical Production of Cold. (Howard Lecture.)

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—Dr. Seymour-Taylor: Urine-Testing.

ROYAL INSTITUTION.—3 P.M. Mr. J. W. Gregory: The Problems of Arctic Geology.

LONDON SKIN HOSPITAL (40, Fitzroy-square, W.).—4 P.M. Mr. J. Startin: Gouty Affections of the Skin.

FRIDAY (12th).—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Mr. W. Wingrave: The Anatomy and Physiology of the Ear.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. J. Taylor: Epilepsy.

ROYAL COLLEGE OF SURGEONS.—5 P.M. Prof. D'Arcy Power: Intussusception.

ROYAL INSTITUTION.—9 P.M. Prof. J. Milne: Recent Advances in Seismology.

SATURDAY (13th).—ROYAL INSTITUTION.—3 P.M. Mr. W. F. Lord: The Growth of the Mediterranean Route to the East.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

LOCAL APPLICATION OF COLD IN PNEUMONIA.

DR. THOMAS J. MAYS of Philadelphia, writing in the *Medical and Surgical Reporter*, describes the treatment of acute pneumonia by ice-bags applied to the chest. He has used this method for 295 patients, only ten of whom died.

Dr. Edith Huntley.—The advertisements are, of course, very sad. Nothing can be done to check them, as the offenders are not upon the Medical Register and therefore owe no allegiance to the General Medical Council; responsibility of publication lies with the editor of the paper. We are glad to know that many journals refuse to insert these disgusting and untruthful advertisements, but at home, as well as in India, there are proprietors not so scrupulous.

Scotus.—The directions as to the manner of the Scotch form of oath are as under. The officer requests the witness to hold up his right hand and to repeat after him the words of the Oath. No book of any kind is used. The witness, holding his right hand above his head, says, "*I swear by Almighty God (as I shall answer to God at the Great Day of Judgment) I will speak the truth, the whole truth, and nothing but the truth.*"

Mr. Champion B. Russell.—There is no doubt a difference between the temperament of dwellers on high ground and that of dwellers in valleys; but the difference is believed to be the result of an influence extending over a long range of time. To make the individuals change environment would not make them mutually exchange mental capacity and moral stability.

Mr. Charles Blake is thanked for his communication, which will receive immediate attention.

Mr. E. J. Lloyd (Bangor).—We much regret the error, which we have noted and explained elsewhere.

MEDICAL PRACTICE IN SOUTH AFRICA.

To the Editors of THE LANCET.

SIRS,—A correspondent in THE LANCET of Jan. 16th (p. 194) gives a very disheartening account of South Africa as a field for medical men, and a perusal of his letter would discourage practitioners from trying their fortunes in that portion of Her Majesty's dominions. From my own knowledge of the country and from what I have learned from friends who have resided in various places in the Cape Colony and the neighbouring provinces and states I think your correspondent's description of the country is entirely unjustified. Take, for example, the district around George Town in Cape Colony. There is at present only one medical man in the place and he has a very large tract of country to attend to. Farmers and colonists have often to come sixty or seventy miles to obtain medical attendance when ill. From Mossel Bay to Kuysna, a distance of about 100 miles, there is but one young practitioner, and this district comprises the rich farming country known as Long Kloof. So also at Mafeking in Bechuanaland there is but one practitioner, yet it is the centre of a large and important district with a growing population. As to the necessity for knowing Dutch, very few medical men in South Africa seem to have acquired it. The cost of living is not nearly so great as represented. Very good accommodation can be had at the boarding houses, which exist in every town and village and which afford excellent board and lodging at the rate of £5 a month. I am, Sirs, yours faithfully,

University Club, Dublin, Jan. 23rd, 1897. W. F. BAILEY.

X. Y. Z.—There is no necessity whatever that the dispenser should be a qualified medical man. We presume that he does not originate the treatment but simply carries out the instructions of the medical officer. The dispensing departments of all the great charities are under the supervision of dispensing chemists, not of medical men.

THE MUSSULMAN DEPUTY.

THE medical members of the French Legislature have so long been the mark of the newspaper wits that of late the jests at their expense have began to pall, but luckily for the Parisian penny-a-liners the appearance upon the Parliamentary scene of Dr. Grenier, the Mussulman deputy, has imparted fresh pungency to their satires. Amongst the elected practitioners several ere this have been remarkable for their peculiarities, but the eccentricity of the latest edition to their number exceeds all that has so far been seen. "What with Catholics and Protestants, Free-thinkers and Jews, the Assembly," says one of the facetious scribes, "was formerly quarrelsome enough and to spare, but now that a fresh apple of discord has been thrown among our legislators in the shape of a pious Mussulman crying, '*La ullah illa ullahi*,' the confusion will be worse confounded than ever." According to another writer the new Deputy for Pontarlier is an ordinary medical practitioner, who has neither given his name to an operation nor invented a new instrument. For his fame he depends entirely upon his religion and his *burnous*. If we may believe the majority of his multitudinous interviewers he is charitable, popular, and beloved of his patients, to say nothing of his celebrity as a member of the Municipality. He declares to all and sundry that it is his mission to preach the Koran and convert the whole French nation to Islam. The comments of the medical journalist who signs himself Dr. Minime are somewhat peculiar. "It is known," says this well-known feuilletonist in the *Journal de Médecine de Paris*, Jan. 3rd, 1897, "that Islamism differs from all other religions in two essential particulars. It sanctions polygamy and constrains its adherents to perform daily ablutions of the face, the hands, and especially of the feet. We need not insist upon the importance of the first of these dogmas. Were polygamy to be made legal the population would increase, many people would be rendered happy, and the number of damsels condemned to single blessedness would diminish to the vanishing point. As for the obligatory performance of ablutions, all medical men and hygienists are aware how advantageous that would be. Can you imagine Frenchmen being obliged to wash their feet night and morning? It would be a transformation—a regeneration of the race. If M. Grenier can bring this to pass he will have done more for hygiene than MM. Monod and A. J. Martin. ... It must be admitted that the religion of Mahomet possesses one marked advantage over ours. The habitual attendance at mosque is compulsory, but no worshipper is allowed to enter with unwashed feet. The day when bathing fountains, similar to those that invariably exist in the ante-chambers of all Mohammedan mosques, are to be found at the doors of our churches a glorious progress will have been realised." The punning journalists say there are rats and spiders in the new deputy's garret (*grenier*); but if Dr. Minime's estimate of the national cleanliness is correct, and Dr. Grenier can succeed in converting his fellow-countrymen to the virtue that stands next to godliness, it should go far towards proving that in his madness there is a good deal of method.

"A WARNING TO MEDICAL MEN."

To the Editors of THE LANCET.

SIRS,—The following facts may be of some use to your readers. A week ago a respectably-dressed man called upon me with the business card of a cork manufacturer and a small parcel which he stated contained samples. I declined to give an order, but at his urgent request lent him 1*s.* to take him home, as he had inadvertently left half a sovereign behind when he came out in the morning, he said. He stated that the name on the business card was that of his deceased father and that the business was the property of himself and his brother. Feeling suspicious I wrote to the manufacturer whose name appeared on the card, and he replied that a person had called upon him ten days previously who represented that he was in a position to do business for him, as he called upon medical men, chemists, &c., and who offered to work on a commission. On these representations he took away some business cards and nothing had been seen of him since. I may mention that the enterprising traveller was very anxious that I should lend him 2*s.* I grieve to say that I have not heard from him since. I leave it to your discretion as to whether it would be wise to warn practitioners in London. I am, Sirs, yours truly,

Jan. 25th, 1897. E. F. O'FERRALL.

*** Mr. O'Ferrall will find that in our issue of Jan. 9th we printed a warning to our readers against this or a similar impostor.—ED L.

TEA AS A REMEDY IN COMA.

DR. J. A. SEWELL of Mentone writes to us calling attention to the value of strong infusions of green tea in the treatment of coma, and reminding us that THE LANCET of July 16th, 1864, contained an article on the subject by his late father, Dr. James A. Sewell, Professor of Practice of Physic at Laval University, Quebec. This article gives details of four successful cases, the most remarkable of which concerned a female patient, thirty years of age, subject for some years to what she called "spasms of the heart," for which she had been treated by various medical men without any effect. "Latterly she had been using Battley's sedative solution with more benefit, but as she had no attack for some months she had discontinued the use of this remedy for about three months. A short time since she was threatened with one of her usual paroxysms, and, dreading it very much, she had recourse at once to Battley's sedative solution in two-drachm doses; these doses she continued at intervals till she had taken two ounces and a half in about eight hours. Shortly after the last dose she was seized with a slight convulsion and almost immediately became comatose. I saw her at 2 A.M., two hours after the convulsion, and found her in a state of profound coma; pupils contracted; respirations two in the minute, and performed with a great effort; pulse very rapid, small, and extremely irregular; face deathly pale, ghastly, cold, and covered with a clammy sweat; extremities also cold. It was evident that she was under the narcotic influence of the enormous dose of opium which she had swallowed and that death was imminent. As three hours had elapsed since she had taken the last dose I conceived it useless to use the stomach-pump; moreover, in the then state of her respiration I believe the use of that instrument would have been at the risk of her life. As she could not swallow an emetic was equally out of the question. I therefore applied extensive sinapisms to the legs and chest, used the cold douche, and applied ice to the head. Having by this time been joined by my friend Dr. Jackson I suggested the propriety (while waiting for a galvanic battery) of administering an injection of a pint of the strongest possible infusion of green tea per anum, which was done at 3.15 A.M. In half an hour there was a visible improvement in the breathing, which was now six in the minute, accompanied by a slight return of colour to the face and a corresponding improvement in the temperature of the cheeks. The coma continued much the same, but, encouraged by the improvement in the other symptoms, the injection of tea, to which some brandy was added, was repeated at four o'clock. During the next hour we had the satisfaction of observing a gradual return of the respiration to its normal condition, with an improved state of the pupils and a corresponding change in the general temperature of the body. She continued to progress favourably, and between five and six o'clock (or about two and a half hours after the first injection), though she could see nothing, she recognised those about her by their voices, and soon after we were enabled to pronounce her out of danger." Dr. Sewell's other three cases included one of alcoholic poisoning in an infant and two of coma in adults from causes not specified. One of the adults, a man aged forty years, was given a tablespoonful of a strong infusion of tea every twenty minutes; after six doses he showed some improvement, and after four additional doses he became maniacal, but "next day he was himself again." Dr. Sewell believed that the introduction of tea as a nervous stimulant was due to the late Dr. Graves, who recommended its use in the coma of fever.

"TREATMENT OF CHILBLAINS."

To the Editors of THE LANCET.

SIRS,—During such weather as we have lately experienced many of your readers will have had numerous applications for the treatment of chilblains. The following procedure has been practised by me for some winters past with invariable success and prompt and speedy relief in every instance. Having ascertained and localised the focus of each chilblain, whether on hand or foot or elsewhere, resort to the application of the secondary current of a Faradaic battery, increasing the current gradually to high strength. The application must be made direct to the affected part—that is, both poles must be in contact with the affected area, separated only by the area occupied by the chilblain itself. Having first previously dipped the electrodes in saturated sodium chloride solution, maintain the application of the current to each chilblain for from five to fifteen minutes. If the chilblain be watched during the application of the current the tissues will be seen to gradually blanch and the anæmic area due to the pressure of the electrodes will be seen to creep outwards, even though care be taken not to increase the pressure. This blanching begins after about five minutes of the passage of the current. The result of this procedure is as follows: the itching as completely and promptly stopped by the first application, and a second, one or two days afterwards, usually suffices to effect a cure; seldom, if ever, does a third or fourth application become necessary. I have never in a single instance in an extensive trial of this method known it to fail to effect a cure in three or four days, to the great delight and gratitude of the victim. The treatment is handy and rapid, and I feel sure will be of use to many or I would not ask your valuable space for its advocation.

I am, Sirs, yours faithfully,
F. W. FORBES ROSS, M.D. Edin.

Chepstow-place, Bayswater, W., Jan. 28th, 1897.

Enquiry.—It is a matter for mutual agreement entirely. We are of opinion that the best arrangement would be that A and B should each continue to receive the profits of his own practice. If it is a convenience to A to receive all the purchase money three months before the purchase is complete, it is equally a convenience to B to have three months' introduction as a partner. The matters should have been taken into consideration before the price was fixed.

OLD ENGRAVED COPPERPLATES.

WE have received from Mr. Andrew Tuer, Managing Director of The Leadenhall Press, Ltd., 50, Leadenhall-street, E.C., a communication which may be of interest to some of our readers. Mr. Tuer desires to purchase old engraved copperplates of any size, with figures, views, portraits, miscellaneous and fanciful and scrap subjects, and any old engravings of all kinds, plain and coloured, and old scrap-books.

Beta.—The Apothecaries' Hall of Ireland was the corporation to whose examinations our correspondent refers. The Royal College of Physicians of Ireland was not mentioned. The Royal College of Surgeons in Ireland was only alluded to incidentally, because this body and the Apothecaries' Hall of Ireland formerly had a conjoint scheme. This scheme was closed for new entries on June 30th, 1895, students who entered before that date being allowed to complete their examinations.

D. S.—We are not able to make an absolute promise with regard to the insertion of any paper.

TREATMENT OF HAY FEVER AT NEUENAHR.

To the Editors of THE LANCET.

SIRS,—I should be greatly obliged if any of your correspondents would give me information as to the efficacy of the treatment for hay fever as carried out at the above place.

I am, Sirs, yours faithfully,
Jan. 30th, 1897. M.D. CANTAB.

A. B. C.—The cases have been brought to our knowledge. The name of the medical man in the second case, published first, is not given, and probably in both instances the fancied improvement never took place. The rays have been tried also for the resolution of tuberculous deposit, but with no success. We have seen no reliable account of any improvement following the use of the rays upon malignant growths, and it is difficult to see how improvement could logically be expected.

ANTISEPTIC MIDWIFERY.

DR. J. DYSART MCCAW has written referring us to certain papers published in 1884 and 1889. In the first paper he states that he "communicated the then new-fangled Continental methods of using corrosive sublimate in midwifery work" to the medical profession in England through the columns of the *Provincial Medical Journal*. In the second he gave the results of his own practice.

R. D.—The case requires no special treatment whatever. We never recommend individual practitioners. From our correspondent's own showing he is in good and careful hands. Why should he change?

HYPODERMIC MEDICATION.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me (1) which form of hypodermic syringe now in use they find most convenient? (2) whether tabloids for the various solutions make the more reliable form for administering hypodermic injections? and (3) whose tabloids are the best.

I am, Sirs, yours truly,
Feb. 3rd, 1897. REGULAR READER.

Rocket.—1. The information under this head is too scanty. It is essential to know how B came to be absent. When a medical man is engaged to attend a woman, he is entitled to his fee *unless he fails in his portion of the contract.* 2. The prevailing idea of the profession is to the above effect. Our correspondent will perceive that an engagement to attend such cases is of itself a hindering and inconvenient thing, apart from the actual attendance.

THE STANDARD ACCESS "EYE."

WE have received some diagrams from Messrs Mooney and Co. of Manchester illustrating inspection eyes for drains. They are made applicable to straight pipes, bends, junctions, or disconnecting traps; the idea is to supersede the more expensive inspection chamber. The importance of some ready means of access to various points of house drains is universally recognised, and where the expense prohibits the use of the chamber these Standard Access "Eyes" are preferable to the ordinary junction. They allow a rod to be passed either up or down the drain. They are very suitable for use in short branches or for such drains as are at no great depth below the surface of the ground.

A Medical Officer.—Our correspondent's letter will receive attention. He will find his question concerning vaccination answered in our columns already.

M.R.C.P.—No one can consider A. to have acted nicely, but his conduct could not be brought under the notice of the General Medical Council.

F.R.S. Edin. (and others).—The reference should have been to the *North Eastern Daily Gazette.*

Mr. W. G. Thistle is thanked for his letter, which will be inserted.

Justitia has omitted to give his name and address.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

HAZELINE

A Simple Drug.

(*Hamamelis Virginica.*)

A shrub indigenous to the Northern American continent. The fresh leaves and bark, from which Hazeline is prepared, possess powerful astringent, anodyne and styptic properties.

CLINICAL experience has established the fact that the active principles of the witch hazel can be extracted only by careful distillation from the fresh green twigs and leaves of the plant. That Hazeline is prepared with due regard to these essentials is proved by its great value as an anodyne, styptic and astringent, and by opinions such as that of a leading therapeutic lecturer, who reported as follows in the *British Medical Journal* of 12th March, 1892:—"I have not found either the tincture or the liquid extract, both of which are to be found among the recent additions to the Pharmacopoeia, nearly so satisfactory." Hazeline is indicated internally in haemoptysis, haematemesis, in all passive haemorrhages, and in what is known as haemorrhagic diathesis. Externally it is used in cases of bleeding from cuts, wounds, etc. It is supplied in small and large bottles, at 1s. 2d. and 3s. 6d. each.

ABSTRACT OF

The Hunterian Lectures

ON

THE PATHOLOGY AND SURGERY OF INTUSSUSCEPTION.

Delivered at the Royal College of Surgeons of England,

BY D'ARCY POWER, M.A., M.B. OXON., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR OF SURGERY AND PATHOLOGY; SURGEON TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

LECTURE I.

Delivered on Feb. 8th.

[The full text of this lecture will be published in the forthcoming number of the Journal of Pathology and Bacteriology. We print a brief summary of it to form an introduction to the second and third lectures.]

SOME POINTS IN THE MINUTE ANATOMY OF INTUSSUSCEPTION.

MR. D'ARCY POWER began his course of lectures with an apology for selecting so time-worn a subject as intussusception, but he justified his choice by saying that it was one which had occupied the thoughts of John Hunter, the great master in pathology, after whom the chair he occupied was named. Very little seemed to be known about the minute anatomical changes occurring in intussusception, though the various museums attached to the medical schools and hospitals throughout the country contained an abundance of material for its study. The earliest changes were shown in sections from the intestine of a child, aged eight months, upon whom he had performed an operation successfully thirteen and a half hours after the appearance of the first symptoms of intussusception. The child died a few days later with symptoms of paralysis of the bowel, but without peritonitis. The mucous membrane of the invaginated colon was healthy except for an increased number of goblet cells in its crypts of Lieberkühn. Much blood had been extravasated into the sub-mucous tissue, though no clotting had occurred. The circular layer of muscle was healthy, but the longitudinal layer was œdematous and was separated from the serous coat by many large venous and lymphatic channels. The next section was taken from an experimental invagination made in a cat a week previously. The histological changes were again more marked in the mucous and sub-mucous layers than in the muscular coat, but the extravasation of blood was chiefly in the mucous membrane, whilst the swelling of the sub-mucous tissue was due to œdema. The sections from the experimental invagination in a cat were compared with a spontaneous intussusception which had killed a dog. The extravasation of blood in the dog's intestine had done serious injury to the mucous membrane and to the sub-mucous tissue, but the chief alteration in its structure had taken place in the muscular coat, where the circular fibres were separated by the œdema and had degenerated. Some of the later changes in intussusception were illustrated by sections taken from John Hunter's own specimen, which was particularly well preserved, because at the time the patient died spirit was so cheap and strong that its retailers used to advertise that their customers might be "drunk for a penny, dead drunk for twopence, and straw to lie upon for nothing." Hunter's specimen, which led him to write his celebrated paper upon "Introsusception," was taken from the body of a child who died sixty hours after the first symptoms of illness had been recognised. Microscopical examination showed that the mucous membrane of the intestine was healthy, but that parts of its surface were covered with blood clot. The whole of the sub-mucous tissue was engorged and œdematous. The circular layer of muscle was more injured than the longitudinal layer, whilst the mesocæcum was thickened by bands of fibrin. A lymphatic gland which had been involved in the invagination was congested.

The latest changes occurring in intussusception were shown in sections taken through the ilea of children in whom the sub-mucous and serous coats of the intestine were suppurating whilst the mucous and muscular layers were comparatively healthy. The changes which take place in the intestines of adults as a result of intussusception were next shown to be identical in some points with those occurring in the more delicate tissues of children, though in other points they differed widely. The frequent association of adult intussusception with polypi and other growths in the intestinal canal led to the changes being of a more chronic nature. The villi of the mucous membrane, therefore, became converted into mere tags of connective tissue, but the extravasation of blood into the sub-mucous tissue remained a marked feature in the invaginated bowel. In a case of chronic intussusception taken from the body of a man, aged twenty-seven years, the sub-mucous and muscular layers had become converted into dense fibrous tissue, whilst the villi were congested, but had not undergone any mummifying change into connective tissue. Sections from portions of bowel which had been exfoliated with and without the recovery of the patient were then exhibited. It appeared that the intestine occasionally underwent a sclerosing process before it was cast off, but that more frequently it had undergone so much tryptic digestion as to leave only a skeleton of connective tissue (reticulin) which was still sufficiently coherent to be passed as a complete cylinder. An examination of the scarred intestine at the point of separation showed that the mucous membrane repaired itself, and that the sub-mucous tissue became continuous with the serous coat by layers of scar tissue which ran through the interrupted muscular coat. The exact method of repair in these cases required more careful examination, for the specimens which had been examined were not sufficiently well preserved to allow a satisfactory microscopical examination to be made.

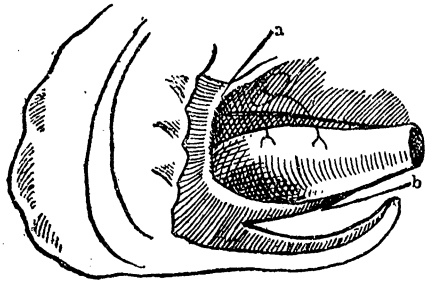
The rarer forms of intussusception were then considered, and sections were shown from a case of descending and retrograde intussusception occurring in the same patient. It was clear that in this instance the descending or ordinary form of invagination was the primary one, whilst the retrograde invagination had been produced much later, though it was not of the "agonic" type. Sections were then shown from a polypoid tumour associated with an intussusception occurring in a woman. The tumour proved to be a sarcoma, but the intestinal villi contained numerous oval bodies which seemed to be thrombosed vessels. The thrombosis was limited to the villi, for the bloodvessels in the deeper part of the mucous membrane and in the sub-mucous tissue contained ordinary post-mortem clots. Mr. D'Arcy Power concluded his lecture, which was illustrated throughout with microphotographs, by an allusion to Dr. Vierthuff's and Dr. Sutherland's cases of intussusception occurring in the course of attacks of purpura. He also pointed out the various ways in which a Meckel's diverticulum, whether it was open or closed, might cause the rarest forms of intussusception; and he showed a specimen in which an obscure case of intussusception in an old person was proved by microscopic examination to be associated with carcinoma, that most usual cause of invagination in late adult life.

LECTURE II.

Delivered on Feb. 10th.

THE PATHOLOGY OF INTUSSUSCEPTION.

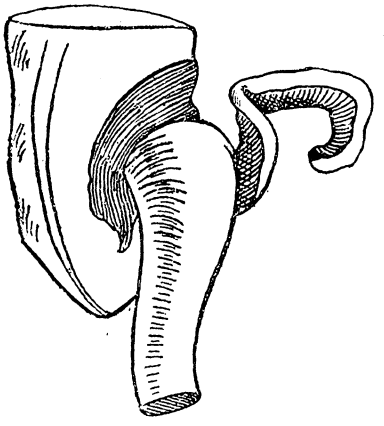
IN the former lecture we ascertained some of the minute structural changes which take place in invaginated portions of the intestine, and we were then on the firm ground of fact. In the present lecture I propose to consider some points in the pathology of intussusception, and we shall find that we are almost at once driven to theorise. Every advance in pathology must be made by combining the results obtained from a consideration of anatomical, physiological, and clinical facts, for the science is the mistress of all these its handmaidens. It will, therefore, be necessary to follow intussusception along these lines, and afterwards to draw certain conclusions from the premises thus obtained.



Anatomical.—It behoves us to make a careful anatomical examination of the ileo-cæcal portion of the alimentary canal, because from 40 to 60 per cent. of all the recorded cases of intussusception are said to occur at this part of the intestine. My work, therefore, has been limited to the ileo-colic angle, and I have been very greatly assisted by Dr. Pickard and Dr. Hayne, successively the senior resident medical officers at the Victoria Hospital for Children. These gentlemen have given me many opportunities to examine the ileo-cæcal region

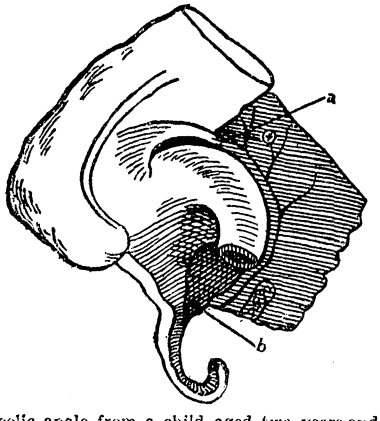
Hosted by Google

in the bodies of children from a few days old up to the age of fifteen years.



[The result of these observations were set out in a table, which showed that, of the forty-four cases examined, two were fœtuses near full term, and forty-two cases were children whose ages ranged from five days to fifteen and a half years. In each case the length of the mesentery was recorded and also the diameters of the ileum and colon, and the breadth of the ileo-cæcal valve; the arrangement of the peritoneal folds and mesenteric glands was also described.]

FIG. 1.



A simple but complete form of ileo-colic angle from a girl, aged eleven years. The ileo-colic fossa is well formed and the axis of the ileum is almost horizontal. *a*, The ileo-colic fold. *b*, The ileo-cæcal fold.

FIG. 2.

The ileo-colic angle of a child, aged twenty-three months. The ileo-colic fossa is absent and the axis of the ileum is directed upwards to end in the large intestine.

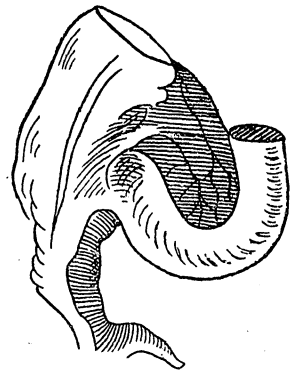


FIG. 3.

The ileo-colic angle from a child, aged two years and eight months. The ileo-colic fossa, *a*, is incomplete, but there is a very large and deep ileo-cæcal fossa. *b*, The axis of the ileum is concave downwards.

(*a*) *The mesentery.*—The length of the mesentery is a matter of interest in considering the pathology of intussusception, because the size of the invagination depends materially upon the length of the mesentery or upon its extensibility. The length of the mesentery is singularly constant in all the specimens measured; and as the age of the individuals varied considerably this means that its proportion to the length of the body was much greater in infants than in older children. The intestines should, therefore, be

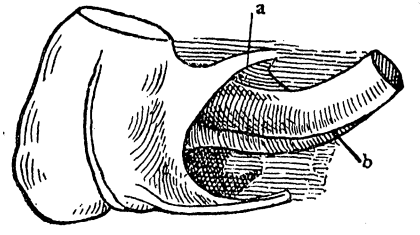

FIG. 4.

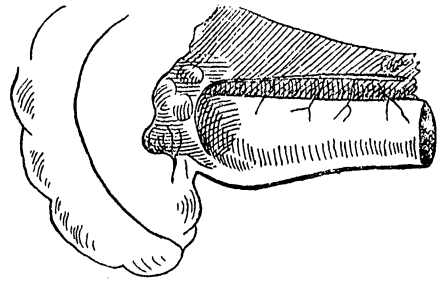
The ileo-colic angle of a child, aged fifteen weeks. The ileo-colic fossa is incomplete and the axis of the ileum is convex downwards.

capable of a greater range of movement in children than in adults. This result is confirmed by the practical experience of all surgeons who have had to open the abdomen for the relief of intussusception in children, for the intestines are nearly always so freely moveable that it is easy to bring the tumour into the wound. The mesenteric lymphatic glands

FIG. 5.



The ileo-colic angle of a girl, aged fourteen years. The ileo-colic fold, *a*, and the ileo-cæcal fold, *b*, are unusually well developed. The axis of the ileum is nearly horizontal.

vary greatly in their size and distribution. They are discrete and seed-like in many specimens, and in others they are aggregated to form a mass of lymphoid tissue.

b. The ileo-colic angle.—The point of union of the small intestine with the large intestine next engaged my attention. The axis of the ileum at this point was horizontal (Fig. 1) in

FIG. 6.

The ileo-colic angle of a child, aged eight weeks. The ileo-colic fossa is incomplete, but its roof is studded and thickened with lymphatic glands. The axis of the ileum is horizontal.

20 cases; in 14 it sloped upwards to open into the large intestine (Fig. 2); in 3 it was concave downwards (Fig. 3), and in one it was convex downwards (Fig. 4). The actual line of union of the ileum with the colon is hidden both in front and behind by folds of the peritoneum, the arrangement of which

Hosted by Google

has been made familiar to us by the works of Mr. Treves,[1] and of my friends Dr. Rolleston and Mr. Lockwood[2] in England, and of Dr. Perignon[3] in France. The folds give rise to pouches the extent and complexity of which vary in each specimen, but as a rule those in front of the ileo-colic junction are simpler than those behind and below it. The ileo-colic fossa resolves itself into two great types, the complete (Fig. 1) and the incomplete (Fig. 6), whilst in some cases (Fig. 2) it is entirely absent. The complete fossa (Figs. 1 and 5), which is usually coexistent with the simpler types of cæcum, is that in which the ileo-colic fold stretches in a wide sweep from the ileo-colic mesentery across the ileum to form the mesentery of the appendix. This fold is attached to the cæcum externally, and terminates internally in a crescentic margin which forms the mouth of the ileo-colic fossa. This border is sometimes thick and rounded (Figs. 1 and 6), at other times thin and membranous (Fig. 5), and the ileo-colic fold may often contain one or more lymphatic glands (Fig. 6). The lower wall of the pouch is formed by the ileo-cæcal fold in the most simple instances. This fold is attached for a varying distance along the lower border of the ileum, but, like all the other structures in this region, it varies greatly in its development and is often wholly absent. Numerous modifications of this type are seen (Figs. 1 and 5), but they agree in having a pouch of greater or less depth which involves the whole width of the ileum. The incomplete form of pouch (Figs. 3, 4, and 6) occurs when the ileo-colic fold terminates on the anterior surface of the ileum. When there is no pouch (Fig. 2) the ileo-colic fold is attached to the ileum in its whole extent. The peritoneal folds lying behind the ileo-cæcal junction are much larger and more complex than that situated in front of it, and the fossæ formed by them vary so greatly in width, depth, and structure that I have no time at present to describe them adequately. It must suffice to say that they are divisible broadly into the ileo-cæcal (Fig. 3, *b*), which runs upwards behind the ileo-colic junction and the sub-cæcal fossæ, which are situated behind the cæcum, and are less constant than either the ileo-colic or the ileo-cæcal pouches. The course run by an ileo-cæcal intussusception will depend materially upon the arrangement of these peritoneal folds and their fossæ. When the folds are simple the fossæ are small, and if lymphatic glands are absent the case is probably only a simple invagination which can easily be reduced by irrigation of the bowel in its earlier stages, or, if it be left unreduced, will run a chronic course. When the peritoneal folds are complex the fossæ are large, and if the lymphatic glands are numerous so much tissue is necessarily invaginated in addition to the intestine that if early strangulation does not occur extensive adhesions of the puckered mesentery must necessarily be formed which will soon cause the intussusception to become irreducible. Such cases will, therefore, run an acute course.

c. Relative diameters of ileum and colon.—The width of the large intestine at birth is only a few millimetres greater than that of the small intestine, and before birth its diameter is usually the same or even a little less; at the age of fifteen years it is from two and a half to three times as large. The colon begins to grow in girth directly after birth, as might be expected when we remember that its function is to store up and consolidate the refuse food materials until they can be cast out of the body at convenient times and places. A general review of the figures shows that whilst the ileum only rarely doubles its diameter, if eleven or twelve millimetres be assumed to be a fair average width at birth, the large intestine not only often doubles its size, but may even treble or quadruple it. During the early months of life, therefore, there is a rapidly increasing disproportion between the transverse diameters of the large and small intestines.

d. The ileo-cæcal valve.—The last point of anatomical interest to which I directed my attention was the ileo-cæcal valve. The description found in the ordinary text-books of anatomy is substantially correct in a large number of cases, but in many the arrangement differs. The orifice is often oval or circular in the hardened specimens instead of being horizontal, and a part of the valve is frequently so defective that the opening appears to be horseshoe-shaped when it is seen from the cæcum. The ileum nearly always projected for from four to seven millimetres into the lumen of the intestine, and in a few cases the mucous membrane of the ileum was distinctly prolapsed into the large intestine.

Physiological.—Let us turn now from the anatomical to the purely physiological side of the question as to the cause of intussusception. Observation tells us that the peristaltic wave passing along the small intestine ceases at the ileo-cæcal valve and that a new wave is developed there by the contraction of the coats of the large intestine. It is quite possible, therefore, for the end of the ileum to be contracted or even to be absolutely quiescent at the instant when the colon is contracting energetically. The experimental work of Dr. Leubuscher,[4] elaborated and carried to a more successful issue by Professor Nothnagel,[5] has taught us that intussusception is due to one piece of gut swallowing, so to speak, a neighbouring piece, which has become constricted in consequence of local or other causes producing a vigorous contraction of its circular layer of muscle. The important part which is played by the muscular coat of the intestine in producing an intussusception is well seen in two specimens[6] which came from the museum of Mr. George Langstaff. They were taken from dogs which had been dosed with turpith mineral for the cure of the distemper. The signs of intussusception began almost directly after they had taken the drug. The first dog lived two days and the second dog three days. These specimens led me to experiment with turpith mineral to discover whether the intussusceptions were produced by it or were merely of accidental occurrence, and they formed the beginning of a series of experiments upon the effects of increasing the peristalsis of the intestines.

[The lecturer described some experiments made by administering turpith mineral and other drugs to cats, rabbits, and guinea-pigs. In many cases a series of localised contractions of the bowel occurred, separated by relaxed portions, an arrangement very favourable to the formation of intussusceptions. An important point brought out by one of the experiments was that the force exercised by peristalsis is extremely slight. He continued:—]

The feeble force of peristalsis has also been noticed by Professor Cash[7] of Aberdeen, who says that in dogs a weight of from eight to ten grams is sufficient to prevent a well-developed peristaltic wave from executing its object, whilst the traction exercised by a weight of five grams produced much hindrance and caused spasmodic contraction of a propulsive character, which created most distinct discomfort or colic.

Pathological.—A considerable number of the cases of intussusception are merely invaginations of one piece of bowel into another, which is usually of larger calibre, and if there is a great disproportion in width spontaneous reduction may take place, as in a case recorded by Mr. Thomas,[8] occurring in a boy aged sixteen months, in whom he had distinctly felt the invaginated intestine per rectum. When the disproportion between the diameters of the enshcathed and ensheathing intestine is less marked or when much additional tissue is invaginated adhesions are formed, the intussusception becomes irreducible, and in process of time secondary changes take place in the intestine, which lead to strangulation, to gangrene, or to ulceration of the neck of the bowel.

1. *Strangulation.*—Strangulation in intussusception is more often chronic than acute. It is of the true or elastic variety when it occurs in intussusception—that is to say, the invaginated bowel is enclosed in a lumen which is either no bigger than itself, as in the enteric form, or only slightly larger, as in the ileo-cæcal variety; whilst in the ileo-colic type, where the ileum passes through the ileo-cæcal valve, the valve may form an additional constricting agent. During the actual invagination the lumen of the ensheathing intestine must be dilated to its utmost extent. The wall of this portion of the intestine then recoils and exercises sufficient pressure upon the vessels of the mesentery to cause a marked congestion in the tissues of the intussusceptum. The congestion leads to a stagnation in the blood flow, and so to a cellular infiltration, which is best marked at the two points where the vessels are doubled upon themselves—that is to say, at the end of the intussusceptum and at the point where the pressure is exercised, which is the neck.

2. *Gangrene.*—The inflammatory changes which result

Hosted by Google

from a continuance of these conditions lead to gangrene, which may spread slowly from the apex towards the neck of the invaginated piece of gut, though in many cases it appears early and may involve considerable portions of the invaginated bowel. Gangrene, however, is less common in intussusception than it is in hernia, and there are several reasons for this difference between the two conditions which have otherwise many pathological affinities. Intussusception is essentially an affection of children, and in children gangrene of any part is rare, even after the most serious injuries, partly because their vascular system is so healthy that it adapts itself readily to the most unfavourable conditions, partly because the blood-supply to all growing parts is very abundant, and partly because all young tissues are soft and yielding. In an intussusception, therefore, the bowel passes through an elastic ring which, even when it is inflamed, never offers a resistance in any way comparable with that exercised by the rigid fibrous structures which compress a hernia or an internal strangulation. It is less likely than hernia to set up general peritonitis, because the gangrenous portion is enclosed in a sheath of healthy intestine, for the gangrene in chronic cases nearly always begins in the intussusceptum, though it may afterwards involve the intussuscipiens.

3. *Ulceration.*—The occurrence of ulceration or of necrosis of the intussuscipiens is a much greater danger than gangrene of the intussusceptum, but it is fortunately somewhat less common. It is, however, met with at either end of the intussusception, as well as in the bowel above and below that portion which has been invaginated. We do not yet know the exact course taken by the micro-organisms as they pass through the wall of the bowel, and though I have been engaged in an endeavour to trace their passage, my results are not yet sufficiently advanced to warrant any definite statement, but there seems to be no doubt that micro-organisms begin to traverse the intestinal wall when a loop of bowel has been constricted for a period of from four to forty-eight hours, and that the more completely the blood supply is arrested the more rapidly do they pass. Suppurative peritonitis is not usually set up in anything like so short a space of time, and when it does occur it is more often associated with rupture of the gut from the progress of ulceration due to accidental or additional causes than to the simple extension of suppurative processes through the wall of the intestine. The experiments of Grawitz[9] and of Halstead[10] have shown that even pure cultivations of pyogenic organisms as well as suppurating tissues and particles of fæces do not necessarily cause suppuration when they are introduced directly into a healthy peritoneal cavity. Accessory conditions must be present to enable pus-producing substances to set up a purulent peritonitis, and these accessory conditions seem to have in common the power of preventing absorption or removal of the pyogenic substances from the peritoneal cavity.

Clinical factors.—There are good reasons to believe that intussusception is associated with peculiarities of structure and function in the alimentary canal. In a certain proportion of cases intussusception has occurred in more than one member of a family[11] and in children of parents who have themselves suffered from conditions associated with organic or functional disturbances of the bowels. A remarkable instance of this came under the notice of Mr. Pick[12] in the case of a child, aged fifteen months, who was admitted under his care into St. George's Hospital for the relief of an intussusception. The grandfather and the father of the child had been operated upon for strangulated hernia, and one brother had died from strangulated hernia. Many cases of intussusception have been cured by injection or inflation of the bowel through the rectum, even when the apex of the intussuscepted gut has protruded beyond the anus, and in a few cases such advanced intussusceptions have receded spontaneously, whilst in others when the abdomen has been opened the surgeon[13] has rejoiced to find that the invaginated bowel unfolded itself spontaneously as soon as the merest touch had released the constriction at its neck.

CONCLUSIONS.

The evidence derived from anatomical, physiological, pathological, and clinical data renders it legitimate to assert that ileo-cæcal intussusceptions occur when the colon is considerably larger than the ileum, and is so unduly moveable that it readily allows itself to become invaginated when once the process has begun. This variety of intussusception is essentially an affection of childhood, and such an undue increase in the width of the colon implies either a congenital abnormality or an unduly rapid growth, for at birth the diameter of the large intestine is practically the same as that of the ileum. Such a rapid increase in the width of the large intestine may, perhaps, in some instances, render the ileo cæcal valve less competent to guard the end of the ileum, because the valve is not capable of very rapid growth if it is to be firm. Unduly rapid growth of the large intestine may thus allow the end of the ileum to become prolapsed into the colon, and under suitable conditions such a prolapse may serve as the starting point of an intussusception. Though anatomical peculiarities are important factors in the production of an intussusception, the physiological factors are no less important, for they apply in all probability to every form of invagination, whether it is of the enteric variety, the ileo-cæcal, or the colic. The physiological factor is much less easy to specify, for it is almost certainly an individual peculiarity. It may be stated broadly, however, that as regards the ileo-cæcal portion of the intestine the increased mobility, coupled with the unduly rapid growth in the width of the large intestine, is probably associated with increased and irregular peristaltic movements of the large intestine. The cause of intussusception is obscure, but clinical evidence shows that it may be produced mechanically if suitable anatomical and physiological conditions be present. Amongst such mechanical causes are direct injury to the abdomen,[14] sudden and violent muscular efforts,[15] gymnastic movements,[16] jolting or dandling,[17] paroxysmal coughing as in whooping-cough,[18] or it may even be the reward of greediness, as in the cases recorded by Max Bauer[19] and Leichtenstern,[20] in which men were suddenly seized with symptoms of intussusception shortly after eating a quantity of cherries—stones and all. It is, indeed, no matter of surprise that such causes should produce an intussusception, for any of them would lead to a sudden and limited constriction of the intestine associated with an active peristaltic movement of a neighbouring portion sufficient to draw the receiving layer of the gut over the contracted portion, which then becomes the apex of the intussusceptum. As soon as the intussusception has been started the anatomical peculiarities again become of paramount importance, for they determine the character of the intussusception. In the ileo-cæcal forms a wide colon with few and simple ileo-colic folds, devoid of glands, will allow the intussusception to run a chronic course even though the amount of bowel invaginated is very great; whilst complex fossæ, with numerous glands at the ileo-colic angle and prolongations of mesentery along the end of the ileum, will no doubt so far steady the ileum as to render its intussusception less likely, though should it occur the additional amount of tissue invaginated will render the impaction peculiarly tight, so that if gangrene is not produced at once early adhesions will be formed and the intussusception will soon become irreducible.

FREEMASONRY: THE RAHERE LODGE, No. 2546.—A meeting of this lodge was held at Frascati's Restaurant on Feb. 9th, Bro. Alfred Cooper, F.R.C.S. Eng., W.M., in the chair. Bros. Horton-Smith, Owen Lankester, Gow, Laming Evans, and Sloane were admitted to the Third Degree in Freemasonry, Bro. Worthington was admitted to the Second Degree, and Mr. Howard Marshall was initiated into Masonry. The brethren afterwards dined together. A sum of ten guineas was voted from the lodge funds to the Royal Medical Benevolent College and one guinea to the Guy's Hospital Re-endowment Fund.

TWO CASES OF DEFORMITY OF THE HAND RELIEVED BY OPERATION.[1]

BY NOBLE SMITH, F.R.C.S. EDIN.,
SURGEON TO THE CITY ORTHOPÆDIC HOSPITAL, AND SURGEON TO THE ALL SAINTS CHILDREN'S HOSPITAL.

CASE 1.—A woman, aged forty-five years, was admitted to the City Orthopædic Hospital on July 13th, 1896. The patient gave the following history of her case:—Ten years previously, while alighting from a tram-car, she was thrown off under a passing vehicle and her left hand was crushed by one of the wheels. She was taken to the Royal Free Hospital, where the hand was dressed, and where a few weeks later it was found necessary to amputate the end of the second finger. Two years later, finding that her hand was becoming contracted and was very painful, she went to the Mildmay Hospital, where the end of the little finger was amputated. During the next few years she underwent many operations, apparently for the removal of diseased bone, but the hand gradually contracted more and more, the pain became very severe and the hand absolutely useless, so that amputation was proposed, at one of the London hospitals, as the only effective remedy. The patient then came to the City Orthopædic Hospital. When admitted she was in an emaciated condition, and was suffering extreme pain in the affected part. There was a trophic ulcer on the back of the hand discharging freely. The hand was so tightly clenched, that it was impossible to separate the mutilated thumb from the fingers or the fingers from the palm of the hand, and the skin had a "glossy" appearance (Fig. 1). On July 16th I

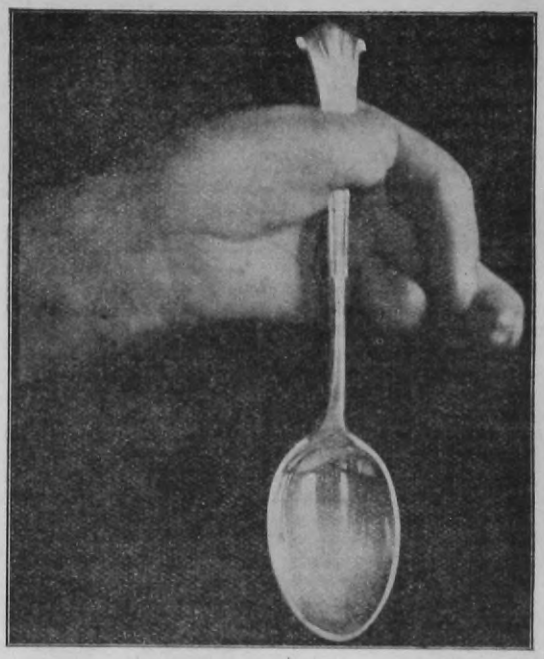

FIG. 1.

The hand before operation.

performed the following operation. A transverse incision was made across the front of the wrist and the tendons of the palmaris longus and flexor sublimis muscles and the ulnar and median nerves were divided. The median nerve was much enlarged. After the tendons were divided it was possible to extend the fingers into a fairly good position, but bearing in mind the extreme sensibility of the nerves supplying the hand, as evinced by the great pain and the "glossy" condition of the skin, I feared that tenotomy alone would not remove the suffering, and realising that, unless this were relieved, the only other resource was amputation, I felt emboldened to divide the nerves in spite of the possibility of serious interruption to the nutrition of the hand by cutting off so large an extent of nerve-supply. The result was very satisfactory. The patient was immediately relieved from much of her pain and in a few days was quite free from suffering, the wound healing up rapidly. A few weeks later I noted that the patient was free from pain; the trophic ulcer was healing; she could move the fingers slightly and could grasp a spoon or other article between her stump of the thumb and her fingers (Fig. 2). Since that period the ulcer has healed up entirely, and although there is considerable stiffness in the fingers, the fact of the patient being able to grasp renders the hand a very useful one. On Jan. 11th I divided a tense band of fascia which passed from the base of the thumb towards the base of the middle finger, because this part was contracting.

FIG. 2.

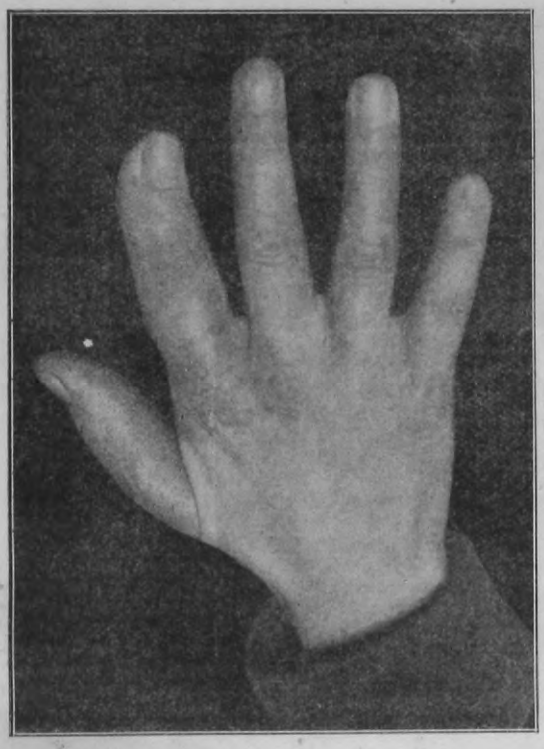
The same three months after operation.

I also broke down some of the stiff finger-joints. As regards numbness caused by the neurotomy, the patient made no

FIG. 3.

Skiagraph of hand before operation.

complaint except upon inquiry about a fortnight after the operation. The loss of the pain was such a relief to her that the numbness was doubtless felt as a benefit. The progress



[1] These cases were shown and described at the meeting of the Medical Society of London on Feb. 8th, 1897.

Hosted by Google

was so satisfactory that it was not until November—that is, four months after operation—that I tested the sensation of the skin, when I found it very good. There was a small area of numbness in the palm at the base of the middle and ring fingers, but not elsewhere, and the two points of a pair of scissors could be separately detected in the other parts.

CASE 2.—A woman, aged twenty-three years, gave the following history of her case: At the age of fifteen months she fell down some steps and when picked up it was found that the thumb and index finger of her right hand had "doubled up." Ten years later, finding that the finger was becoming crooked and abnormally large, the patient was taken to a hospital, where it was said that amputation was the only remedy. The patient did not obtain any other advice until she came to the City Orthopædic Hospital a year ago as an out-patient. The thumb and index finger were then found to be much enlarged and the distal end of the index finger was turned in the ulnar

FIG. 4.

From a photograph of hand taken January, 1897.

direction. The patient was a waitress and she became unable to do her work properly, especially as she could not cut up bread and butter, which was one of her duties. The exact nature of the enlargement was not clear, but it so closely simulated the appearance of congenital hypertrophy that I thought the bones were probably enlarged and that there was an excess of fatty tissue. Mr. Sydney Rowland took a skiagraph of the hand (Fig. 3) which showed that the bones were normal as to size and that the enlargement was entirely due to soft tissue. The Roentgen rays also showed the exact shape of the last phalangeal joint of the index finger, the deformity being produced by irregularity in the shape of both of the bones forming that joint. I operated at first for the lipoma, which I found diffused between the tendons in all directions. I was able to pull out long threads of the fatty nodules which probably come under the denomination of lipoma arborescens of T. Muller. Billroth refers to the analogy between this form of lipoma and the proliferation of fat in the processes of the peritoneum, of the large intestine (the appendices epiploicæ), and other serous membranes. This variety, says Billroth, is extraordinarily rare. Bland Sutton states that diffuse lipomata do not admit of removal, and certainly in this case to have removed all the redundant fat would have been a tedious procedure, but the result of removing a great portion of it was very satisfactory. The immediate diminution in size enabled the patient to use her hand with much less inconvenience, and in the course of some weeks the affected part became still smaller. It was now found that the bend at the end of the index finger was a source of great inconvenience, as it would catch the middle finger. I therefore cut down upon the radial side of the finger and cut the second phalanx transversely with bone forceps nearly to the ulnar border. I then forcibly broke the remaining piece of bone bringing the finger into a straight line. There remains a very slight inclination of the terminal phalanx towards the middle finger, but this gives the patient no inconvenience. The skiagraph shows the hand before the operation, and the photograph (Fig. 4) depicts its appearance at the present time. The hand is now perfectly useful, but if necessary more of the fatty tissue will be removed by further operation.

Queen Anne-street, W.

AN UNUSUAL CASE OF TUBAL ABORTION.

BY J. BLAND SUTTON, F.R.C.S. ENG.,
SURGEON TO THE CHELSEA HOSPITAL FOR WOMEN AND ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

THE following is a record of the most curious case of tubal abortion which has come under my notice. In addition to its novelty there are several points of clinical interest well worth consideration, as they demonstrate the fact that under some conditions tubal abortion can be differentiated from tubal rupture by the clinical signs.

A married woman, aged forty-one years, the mother of four children, was last pregnant in May, 1886. From that date she continued regularly to menstruate till June, 1896. In that month and in July, August, and September the usual menstrual period was represented on each occasion merely by a "slight loss." On July 28th the patient had severe pain in the lower part of the abdomen lasting three hours. On Aug. 14th a similar attack occurred. On Sept. 15th she was again in great pain, which lasted five days. The pain diminished in severity but did not wholly subside, and she sought relief at the Chelsea Hospital for Women, where she was examined by Dr. Arthur Giles, who detected a swelling

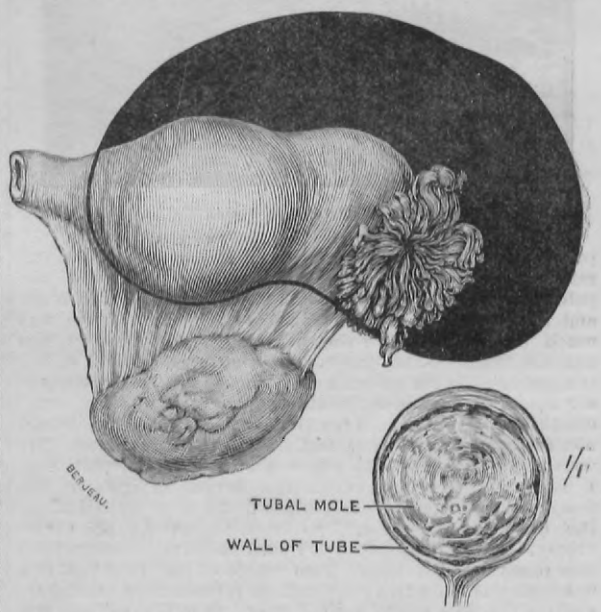


Figure of a gravid tube. The dark outline represents the shape and size of the smallest clot. It also shows the shape of the ampulla of the tube when distended.

in the left half of the pelvis. From the physical signs and the history he regarded the case as "tubal pregnancy and very probably tubal abortion," and sent her into the ward. On examining the patient I found the left half of the pelvis occupied by a semi-solid swelling which extended into the

Hosted by Google

false pelvis and could be felt above the brim. The cervix was soft and patulous. The uterine cavity measured three and a half inches. There was slight bleeding from the uterus. The history and the physical signs were those of repeated hæmorrhage from a gravid tube. On Oct. 19th cœliotomy was performed. On entering the cœlom (peritoneal cavity) I found a clot, the size and shape of the dark outline in the figure, lying in a fold of omentum. It was removed. Beneath it lay a second clot of precisely the same shape, but much larger. On removing this a third clot was found in the recto-vaginal fossa of twice the dimensions but of exactly the same shape as the other clots. A rounded, hard body was felt in the left tube. I then removed the ovary, tube, and adjacent parts of the meso-salpinx in the usual way. The right ovary and tube being normal were not interfered with. The patient recovered quickly and completely.

The clots were in shape reniform; the exterior of each was laminated like the blood in the wall of a sacculated aneurysm or in the sac of an old hæmatocele of the tunica vaginalis testis, but the central parts consisted of ordinary clot. The hard body in the tube was a "mole," and on microscopic examination yielded many chorionic villi in cross section. The ostium abdominale was widely patent and the ampullary wall thick, succulent, and entire. The case was one of "incomplete tubal abortion," but peculiar in this respect: as the blood collected and distended the tubal ampulla it firmly clotted and was then discharged with pain through the tubal ostium into the recto-vaginal pouch. The "delivery," so to speak, of each clot coincided with the three definite attacks of "pains" in July, in August, and in September.

The only record I know which is in any way parallel is by Noble. In a case of tubal abortion the blood clots in the pelvis "were coiled up as though they had been ground through a sausage machine." This was due to the blood clotting in the tube, and the clot was then forced out as a sausage-shaped mass by the continuance of the bleeding. The shape of the clot represented in the illustration is exactly that assumed by the ampullary section of the Fallopian tube when in the condition of hydrosalpinx.

Queen Anne-street, W.

THE GLANDULAR FEVER OF CHILDHOOD: A CASE IN AN INFANT AGED SIX MONTHS.

BY T. EDWARD SANDALL, M.B., B.C. CANTAB.,
MEDICAL OFFICER OF HEALTH OF ALFORD; LATE HOUSE PHYSICIAN AND HOUSE SURGEON TO THE CHARING-CROSS HOSPITAL.

I HAD drawn up a report of the following case before I saw the valuable paper of Dr. Dawson Williams in THE LANCET of Jan. 16th, 1897, and I think that the notes of this case will be of sufficient interest in connexion with the subject of glandular fever in childhood to be published.

The patient, a healthy infant six months old, was apparently well on Nov. 10th, 1896, but was restless and fretful during the night, though nothing definitely wrong was noticed on the morning of the 11th. At midday, however, the mother noticed a slight swelling beneath the angle of the jaw on the right side, and upon examination I found the glands at the anterior border of the sterno-mastoid enlarged, causing a swelling about the size of a pigeon's egg, which did not, however, seem tender to the touch. The throat was apparently quite normal, the tonsils were not enlarged, and there was no congestion or abnormal redness. The temperature was 102·4° F. and the pulse 160. There was no cough or dyspnœa and the child did not seem to be in pain. On the evening of the same day the temperature rose to 103° and the pulse to 200 per minute, while the swelling was considerably larger; hot fomentations were ordered and twenty minims of brandy every four hours. On the 12th the temperature was 102° and the pulse 160. The swelling was now of the size of a hen's egg in the anterior triangle of the neck. Nothing abnormal could be detected in the throat; the bowels were open and the child took food well. Mr. A. E. Odling, who kindly saw the case with me, agreed that it was a case of primary glandular swelling; the hot fomentations were continued and twenty minims of brandy given each time the child was fed, with a grain of carbonate of ammonia every four hours. On the 13th and 14th the child remained in the same condition, the temperature varying from 102° in the morning to 102·6° in the evening and the pulse-rate from 160 to 170. The swelling appeared stationary, with the skin slightly reddened over it, and there was little or no tenderness on palpation. The bowels acted regularly and the child continued to take nourishment well. On the 16th the temperature fell to 101°, the pulse keeping at 160, and the child seemed better. The improvement continued for the next three days, and on the morning of the 20th the temperature was 99·4°, the swelling being slightly reduced. Gradual improvement continued for the next few days, and on the 26th the temperature fell to normal for the first time, the pulse being 144 per minute. The skin was reddened at one point over the swelling and suppuration appeared imminent, but there was no tenderness on pressure. No other glands at any time during the illness were enlarged, and after the first day or two the child seemed fairly well, in spite of the temperature, and there were no other symptoms beyond those described. The swelling gradually subsided, but the skin was reddened and the glands could be felt distinctly enlarged more than three weeks afterwards. It is interesting to note that the child cut his first tooth on Dec. 5th, twenty-four days after the appearance of the glandular swelling.

At the time I was somewhat puzzled as to the exact diagnosis, and I therefore took careful notes of the case, as I had not previously observed one of a similar character. As far as I could gather there was no source of infection; the patient was an only child, and no other children in the district were similarly affected to my knowledge. A few cases of tonsillitis in adults were, however, under my care at the time. Dr. Dawson Williams does not refer in his paper in THE LANCET of Jan. 16th to "glandular fever" in so young an infant as the case I have described. In my case the tender age (six months) and the limitation of the glandular swelling, as far as I could ascertain, to one side of the neck are worthy of note. The child is now (February, 1897) in excellent health.

Alford.

DYSENTERY AND ITS TREATMENT.

WITH AN ACCOUNT OF SIX YEARS' EXPERIENCE IN THE TRANSVAAL AND MATABELELAND IN THE USE OF SOME VARIETIES OF MONSONIA AS THE CURATIVE AGENT.

BY JOHN MABERLY, M.R.C.S. ENG., L.R.C.P. LOND.

(*Concluded from p. 372.*)

CASE 80. *Chronic dysentery.*—This case, which lasted from Dec. 21st, 1893, to Jan. 2nd, 1894, was treated similarly to Case 79. An enema of warm water was given every other day. The patient made a complete recovery. There was no relapse to June, 1896.

CASE 81. *Chronic dysentery followed by hepatitis.*—The patient, a man aged twenty-five years, commenced treatment on Jan. 17th, 1894. He had been healthy up to September, 1893, when he had an attack of dysentery, which lasted four weeks in spite of medical treatment, and was eventually stopped by an infusion of cemirubra. The dysentery recurred at intervals, and from the end of December, 1893, until Jan. 14th, 1894, the patient was continually passing motions mixed with mucus and blood from four to eight times a day. On the 14th the patient came to me for treatment, and was then passing mucus and blood with a great deal of tenesmus about every two hours. An enema containing a very weak solution of Condy's fluid of about one quart was used, and a mixture composed of three drachms of tincture of monsonia, ten minims of tincture of opium, and ten minims of tincture of catechu was administered every four hours. No dysentery or pain occurred till nine hours afterwards, when the symptoms recurred and gradually assumed a severe form, partly, I think, owing to the patient having gone out and got wet. On the 17th the patient again called me in and was then in bed, passing mucus and blood and portions of diseased mucous membrane frequently. He was in great pain and vomited all nourishment taken, both solid and liquid. The pulse was 130, very weak, and the temperature 99·5° F. The tongue was dry and furred. An enema was at once given of about a pint of warm water slightly coloured with Condy's fluid. A powder containing half a grain of morphia and three grains of

Hosted by Google

cocainæ hydrochloras was administered, followed in ten minutes by twelve grains of bismuthi subnitras. This quieted the vomiting, and a quarter of an hour after thirty grains of pulvis ipecacuanhæ were administered in syrupus aurantii. The dose was retained for an hour and then a large quantity of dirty-coloured acid fluid was vomited. The patient then complained of pain all over the abdomen, especially the lower portion A hypodermic injection of four minims of morphia was given and the patient kept absolutely quiet. The bowels were opened twice during the next five hours with very little tenesmus. A small quantity of loose fæcal matter mixed with a little blood and mucus was passed. The dysenteric symptoms gradually returned, and six hours after the first dose a second dose of twenty grains of ipecacuanha was administered with the same precautions. This was retained about half an hour. The patient seemed comparatively comfortable but extremely prostrate. The diet consisted of a little brandy and milk given at intervals. During the night severe vomiting and frequent inclination to empty the bowels returned. On Feb. 18th the patient was exhausted. The pulse was 125 and the temperature 98°. There were great pain and a tendency to vomit frequently. The enema of the 17th was repeated and a hypodermic injection of three minims of morphia was administered. The tongue was still coated with dirty white fur. During the day a gradual improvement was made in the patient's general condition. The vomiting ceased, but very little food was taken, a very small quantity of liquid even producing a tendency to vomit. A dose of twenty grains of ipecacuanha was given in the afternoon with the same precautions as previously. Vomiting occurred in about three-quarters of an hour. On the 19th he had dysenteric motions with frequent tenesmus. A hypodermic injection of three minims of morphia was administered, and half an ounce of tincture of monsonia, twenty minims of tincture of catechu, and ten minims of tincture of opium were prescribed and retained without vomiting. The patient improved during the next four hours and was removed carefully to a cooler room. The bowels were opened once. On the 20th the pulse was 90 and the temperature 98·2°. The last mixture was administered every six hours. During the day the bowels were opened once, the motions being feculent and mixed with a little blood and mucus. At night, as there seemed a good deal of hardness and tension about the abdomen, two drachms of castor oil were given. Two hours afterwards the patient's bowels were opened twice, the motions being loose, dark, and mixed with some stringy mucus. About 10 P.M. one grain of morphia was given by the mouth. The patient had a quiet night. On the 21st the patient was improving. The bowels were opened once, the motion being similar to that on the preceding day. The mixture of monsonia, catechu, and opium was repeated twice during the day. On the 22nd the patient was doing well. The medicine given was the same as on the 21st. The pulse was 80 and the temperature 98·4°. The tongue was cleaning well. On the 23rd the patient was taking his milk diet well. The bowels were opened twice; the motions were loose but otherwise normal. The patient sat up in his room. The medicine was discontinued. On the 24th and 25th the patient rapidly regained strength. The pulse was 86 and the temperature 98·6°. The bowels were opened once normally. On the evening of the 25th the patient complained of pain across the loin and scarcity of urine. Three ounces of hot, fresh infusion of buchu were made and administered, which relieved the symptoms. The patient had a good night. On the 26th, about 3 P.M., the patient was seized with two or three severe rigors, followed by a sudden rise of temperature to 103° and the pulse to 114. There was great pain over the region of the right lobe of the liver. There was tenderness on pressure over the gall-bladder, but no enlargement was perceptible to the eye or on palpation. On auscultation a grating sound could be heard with inspiration over the region of the liver dulness. Eight grains of calomel were given by the mouth and a subcutaneous injection of morphia (three minims) administered. On the 27th the patient was easier. The temperature was 99 4° and the pulse 108; there was tenderness on pressure over the right lobe of the liver, especially over the gall-bladder, where firm digital pressure caused inclination to vomit. The patient complained of catching pain there on deep inspiration. There was no cough. The tongue was coated white in the centre, but was cleaning at the edges. Hot fomentations were applied over the liver, and linimentum aconiti et iodi (equal parts) painted over the painful area. The bowels not being open half an ounce of castor oil was administered at midday; a small, hard motion was passed at 4 P.M. The temperature was 103°. An enema of hot soap-and-water was given and a large quantity of fæcal matter passed, after which the temperature fell to 99·5°. On the 28th the temperature rose again during the early hours of the morning. Half an ounce of sulphate of soda dissolved in a glassful of water was given. The patient soon after vomited about half a pint of bile. The temperature then fell to 99 4°, but remained variable during the morning. The pulse was very weak (from 120 to 130). The bowels were moved four times (feculent). There was a tendency to reflex vomiting. The patient became very restless towards night. Thirty grains of sulphonal were given. On the 29th the patient slept irregularly till 2 A.M. The temperature was variable (from 101° to 103°). The tendency to vomit continued. The pulse was very weak and the patient extremely exhausted. The pain in the right side continued and there appeared to be a localised peritonitis between the under surface of the liver and intestine. The patient could retain little nourishment except champagne. Two drachms of tincture of monsonia were administered. Hot stupes were continuously applied over the right side. The patient slightly improved during the night. One drachm of tincture of monsonia was given at intervals of four hours twice, and at night five grains of calomel were administered, the bowels not having been opened. The tendency to vomit continued, but a little fluid nourishment was retained. At 7 P.M. the patient was immersed in a hot sitz-bath for about ten minutes and felt much relieved. The temperature was 99·6° and the pulse 115. On the 30th the patient slept irregularly. He had improved slightly in his condition. At midday the temperature was 100° and the pulse 105. About 2 P.M. half an ounce of castor oil was administered, and towards the evening the bowels were opened once. The motion was loose and light brown in colour. The pain and tenderness became less over the liver. Hot stupes were continued and at 8 P.M. twenty grains of sulphonal were administered. On the 31st the patient had a quiet night, and during the day took a fair amount of fluid nourishment. A mixture containing ten minims of tinctura nucis vomicæ, ten minims of acidum hydrochloricum dilutum, and half an ounce of infusum gentianæ was given every six hours, and half a grain of morphia was given at midday. The bowels were not opened. At 3 P.M. half an ounce of sodii sulphas was administered. About four hours afterwards the bowels were opened once. The motion was similar to that on the 30th. The tongue was thinly coated with white fur. The temperature varied between 101·5° and 102·5°, and the pulse was 108. On Feb. 1st four motions were passed—feculent, brown, with a light-coloured sediment. The temperature ranged between 100 8° and 102 5°. The pulse was 100. There was a dull pain in the right side. A pill of mercury (five grains) with hydrochlorate of morphia (a quarter of a grain) was administered and the patient put into a hot sitz-bath containing some mustard. The patient passed a good night, the bowels not being open. On the 2nd the pulse was 100 and the temperature 98 6°. The pain in the right side was almost gone, but the patient complained of a dull, heavy pain in the right arm and shoulder. Two doses of thirty grains of salicin were given at 10 A.M. and 2 P.M. respectively. During the morning the patient had two slight rigors, with a rise of temperature to 100°, which remained till 9 P.M. and then fell to normal. At 8 P.M. a pill of colocynth and hyoscyamus (five grains) was administered. One solid motion was passed. On the 3rd the temperature was 98 2° and the pulse 90. At noon the temperature rose to 102 5°. A mixture containing six grains of quinine, three minims of liquor arsenicalis, and twenty minims of acidum hydrobromicum was ordered every six hours. The evening temperature was 101 8°. On the 4th the midday temperature was 98 4°. There was still some pain in the right arm and shoulder. At night an injection of three minims of morphia was administered. From this date the patient made a comparatively quick recovery with one or two slight rises of temperature which were treated with the same mixture as given on Feb. 3rd, and the patient till 1896 enjoyed excellent health.

CASE 82. *Chronic dysentery.*—The patient, a man aged thirty years, had suffered from dysentery in India. On July 17th, 1894, his temperature was 104° and the pulse 98. The tongue was dry and furred. The skin was dry. The patient suffered from acute dysenteric pains and passed mucus and blood every half-hour. A powder containing ten

Hosted by Google

grains of quinine and ten grains of antifebrine was administered and an enema of hot soap-and-water was given. The patient commenced to perspire profusely in about a quarter of an hour. The pain became much relieved. Four hours afterwards three drachms of tincture of monsonia were administered and repeated every four hours. The dysentery was much relieved, but continued slightly till the 19th. A lead and opium pill was given with each dose of the medicine. The dysenteric symptoms had disappeared by the evening of the 19th. A return of the fever occurred about 8 P.M. I administered two grains of the bark of a tree whose value in intermittent fever I had learned from Kaffirs living in the fever districts of the Murchison Range, Transvaal, but which I was not able to identify, although it belonged, I believe, to the Croton family. The bowels were thoroughly well opened once, after which the patient went to sleep for eight hours. The symptoms all disappeared and the patient made a complete recovery. Up to the time I left the country—a period of nearly two years—he had had no relapse.

CASE 83. *Acute dysentery.*—This was a man, aged forty years, who came under my care on July 19th, 1894. He had been suffering for three days from an acute attack of dysentery, and had been taking powders composed of ten grains of pulvis ipecacuanhæ compositus and pulvis ipecacuanhæ respectively without effect. I at once ordered an enema of about three pints of hot water with a little Condy's fluid. The patient passed a large quantity of fæces. I then administered three drachms of tincture of monsonia, with a lead and opium pill every four hours. Three doses were given. The dysentery entirely stopped after the first dose. On the 20th, at bedtime, four grains of calomel were given. In the morning the patient passed a loose motion with slight tendency to tenesmus. Two more doses of the medicine of the 19th were given during the day, with the result that the dysenteric symptoms disappeared. Up to July, 1896, no recurrence had taken place.

CASE 84. *Acute dysentery.*—The patient, a woman, aged forty-two years, came under treatment on Sept. 20th, 1894. She had been suffering from acute dysentery for two days. The treatment was similar to that in Case 83. She passed dysenteric stools three times after the first dose of medicine, but all bad symptoms disappeared after twenty-four hours.

CASE 85. *Chronic dysentery with sloughing mucous membrane; death from cancrum oris.*—I saw this patient, a girl, aged four and a half years, on Aug. 2nd, 1894. She had been suffering for three weeks previously from whooping-cough and had been treated by a chemist with a mixture containing bromide and belladonna. When called in the child was extremely weak, and besides the whooping-cough was suffering from a severe attack of dysentery, which had commenced six days previously. The patient was frequently passing portions of sloughy mucous membrane mixed with blood. A mixture containing half a drachm each of tincture of monsonia, tincture of callilipis,[1] and syrup of tolu, with ten minims of spirit of chloroform, was given every four hours. At night a powder of six grains each of pulvis ipecacuanhæ compositus and bismuthi subnitras with half a grain of calomel was ordered. The child improved steadily, and on the 4th the dysenteric stools had almost ceased, although the bowels were still too loose. A mixture containing chalk with two minims of tincture of opium and five minims of tincture of catechu was given alternately with the previous mixture every four hours. The whooping-cough was considerably relieved and the bowels became normal. The child took her nourishment well, but did not appear to gain strength as quickly as could be wished. On the 9th the left cheek was noticed to be very much swollen, and on examining the mouth a large sloughing ulcer, evidently cancrum oris, was seen. The child rapidly sank and succumbed early on the morning of the 10th.

CASE 86. *Fever and dysentery.*—A girl, aged three years, came under my care on Sept. 25th, 1894. The patient had been suffering for three days from dysentery. The parents had been giving her chlorodyne without effect. When seen the child was slightly feverish, with bilious symptoms, and was also suffering from dysentery. A powder containing five grains of pulvis ipecacuanhæ compositus, four grains of bismuthi subnitras, and one grain of calomel, was administered at night. The patient passed some mucus mixed with blood and bile. On the 26th one drachm of tincture of monsonia and three minims of spirit of chloroform were ordered every four hours and at night five grains of pulvis ipecacuanhæ compositus with six grains of bismuthi subnitras. The patient was passing some greenish stools without blood, but with slight tenesmus and a little mucus mixed with the motion. On the 27th this treatment was continued. The powder given on the 25th but without the calomel was repeated morning and night. The bowels became normal during the day, but symptoms showed themselves of a slight attack of cerebro-spinal fever with pain in the head and irregular temperature. A mixture of ten grains of bromide of potassium, one grain of chloral hydrate, and fifteen minims of compound tincture of camphor was ordered every six hours, the head to be kept bathed with cold water. The symptoms continued for four days and then gradually disappeared. The bowels were regulated with small doses of calomel when necessary and a Dover's powder was given at night.

CASE 87. *Chronic dysentery.*—On Oct. 17th, 1894, I saw a man, aged thirty-three years, who had had several previous attacks of dysentery, one of which had lasted seventy days, two years before. He had been treated in a military hospital in India. Since then he had been subject to chronic attacks. The present attack had commenced insidiously two weeks before. When seen the patient was passing mucus and blood, frequently with great pain in the abdomen and tenesmus. The temperature was 102° F. The skin was hot and dry. The patient had a jaundiced appearance. Two grains of the powder mentioned in Case 82 were given and the patient vomited about a pint of bilious fluid two hours afterwards. A large enema of warm water was administered and a quantity of fæcal matter was passed. The patient felt much relieved, and a mixture of three drachms of tincture of monsonia with a lead and opium pill (4 grains) were ordered every four hours. On the 18th the bowels were moved three times; the patient was easy and his temperature was normal. The motions contained a little blood and mucus mixed with feculent matter. There was slight tenesmus. On the 19th there were two movements of the bowels. The mucus and blood had disappeared from the motions, but the patient complained of a feeling of distension about the stomach. Half an ounce of castor-oil was given and four hours afterwards a large loose motion was passed. Two doses of tincture of monsonia with a lead and opium pill (5 grains) were given at intervals of six hours. All dysenteric symptoms ceased. The patient was ordered a tonic of two minims of liquor arsenicalis with half an ounce of infusum gentianæ three times a day and made a complete recovery. No relapse occurred to the end of June, 1896—a period of over eighteen months.

CASE 88. *Acute dysentery.*—A man, aged twenty-three years, was seen on Feb. 24th, 1895. The patient was tall and rather poorly nourished, with a history of phthisis on his mother's side. Three days previously the patient was attacked with severe diarrhœa, for which he took large doses of laudanum and afterwards a lead and opium pill on his own account. When seen he was suffering from an acute attack of dysentery, and was passing mucus and blood with a good deal of tenesmus. The temperature was 98° F. and the pulse 90 and feeble. An enema of warm soap-and-water was given and a large quantity of fæces was passed. Four drachms of tincture of monsonia with a lead and opium pill (4 grains) were administered every six hours. The pain and tenesmus ceased, and during the next twelve hours one dysenteric motion was passed with very little straining. Early in the morning of the 25th the tendency to griping pains and tenesmus returned. Another enema was given and the medicine was continued. On the 26th the patient was improving slowly and the motions gradually became feculent with slight tenesmus. On the 27th the enema was repeated and the mixture continued. The patient felt much better, but still had a little pain in the lower part of the abdomen and slight straining. In the afternoon he took a drive into the country, and from that time no recurrence occurred. In June, 1896, he was still in good health.

CASE 89. *Acute dysentery.*—A man, aged twenty-two years, came under my care on Feb. 27th, 1895. He had had an attack of malarial fever two days previously. During the night symptoms of acute dysentery had commenced. When seen at 9 A.M. he was passing mucus and blood frequently with a good deal of tenesmus and pain in the lower regions

[1] Tincture of callilipis is made from the root of a plant of that name, which is peculiar to South Africa. It is used by some of the natives as a cough drug. As such it is not of great value, but in the few cases in which I have used it it has proved of marked value in the treatment of whooping-cough, especially in its late stages.

Hosted by Google

of the abdomen. The temperature was 98·6° F. and the pulse 70. An enema of warm soap-and-water was given and the patient passed a fair amount of fæcal matter. Half an ounce of tincture of monsonia with a lead and opium pill were ordered every four hours. Three doses only were taken and the patient resumed work on the 28th. No relapse occurred.

CASE 90. *Acute dysentery.*—A man, aged thirty-three years, came under treatment on March 12th, 1895. He suffered for two days previously from acute dysentery. He stated that he had been drinking rather heavily of spirit, and three days before he had been for a long walk in the heat of the day and had drunk a large quantity of water from a spruit. The symptoms came on within twelve hours. He had taken chlorodyne in full doses without effect. The same treatment was followed as in Case 89. On the 13th the patient complained of the bowels feeling full and uncomfortable. A large enema of hot soap-and-water was given and a large quantity of fæces was passed. Half an ounce of tincture of monsonia was administered and the patient resumed work in the afternoon.

CASE 91. *Chronic dysentery.*—A man, aged twenty years, had been for two months suffering from chronic dysentery. His first attack occurred in December, 1894, and lasted fourteen days. He came to me on July 13th, 1895. During the previous week the dysentery had been most troublesome during the early morning and daytime, the patient passing mucus and blood seven or eight times a day with a good deal of tenesmus. When seen the temperature was 98·4° F. and the pulse was 60. The tongue was white and flabby. The patient, although naturally strong, appeared very much exhausted. The exertion of walking to the surgery caused him to faint. An enema of weak Condy's fluid and water was administered. He passed a quantity of fæcal matter mixed with a little stringy mucus and blood. The same treatment as in the two previous cases was carried out, with the result that the patient was completely cured in about four days. I did not see him again, but met him some time afterwards, when he told me that no recurrence had taken place. He remained well to June, 1896—eleven months afterwards.

CASE 92. *Acute dysentery.*—A man, aged twenty-seven years, came under my care on Aug. 10th, 1895. He was suffering from an acute attack of dysentery, which had commenced on the previous day. An enema was given and medicine similar to that in the last three cases. He had no recurrence after the second dose of the medicine.

CASE 93. *Chronic dysentery.*—A man, aged twenty-four years, came under treatment on Sept. 14th, 1895. His temperature was 102·4° F. and the pulse was 98. The tongue was thickly coated with a brownish fur. The bowels, according to the patient's statement, had been continuously straining during the last twenty-four hours, accompanied by very severe pain in the lower part of the abdomen. A powder containing eight grains each of phenacetin and quinine was administered in a cachet, and a mixture of three drachms of tincture of monsonia and ten minims of spirit of chloroform was ordered every four hours. An enema of about a pint of warm solution of hydrargyri perchloridum (1 in 3000) was given. This produced violent pain and a feeling of faintness. A hypodermic injection of morphia (four minims) was administered, and the patient remained fairly easy for some hours till about 10 P.M. He then had three or four dysenteric motions slightly streaked with blood. An enema of warm water with a few drops of Condy's fluid was given and the patient felt much eased. On the 15th the straining disappeared and the temperature was 99·5°. The tongue was dirty. There were four motions, which were feculent, with very little mucus. The mixture was continued. On the 16th the temperature was 100·2°. The tongue was coated with dirty brown fur. The patient still strained occasionally, but passed nothing. The cachet of the 14th was repeated and an enema of soap-and-water was given, but without effect. One ounce of castor oil with fifteen minims of tincture of opium was administered. Two hours afterwards the patient passed a large quantity of hard fæcal matter. Tincture of monsonia was continued every six hours. On the 17th the temperature was normal; no motions were passed and the tongue was clean. On the 18th the bowels were normal and the medicine was discontinued, the patient being convalescent. The patient had had two previous attacks of dysentery with violent tormina, and since this attack he has had another which he cured with a fresh infusion of monsonia which a friend made from plants growing on his farm. No relapse has occurred since.

CASES 94, 95, 96, AND 100.—These were all acute cases treated at my own surgery. An enema was given in each case and a mixture of two and a half drachms of tincture of monsonia, fifteen minims of liquor opii sedativus, and six minims of spiritus chloroformi every four or six hours was ordered.

CASES 97, 98, AND 99.—These were all in one family—a mother and two children. The mother had been suffering for two months from chronic dysentery, which had been treated in various ways by another practitioner. The mixture given in the four preceding cases was given. As she had been taking castor oil no enema was necessary. The children (Cases 98 and 99) were both acute cases. Enemata were given and the same mixture ordered, Case 99, a child, taking one-fourth of the doses mentioned.

In discussing the foregoing cases it will be better to divide them into two classes, acute and chronic. First, acute. Out of 100 cases recorded ninety come under the heading of acute. In none of these was ipecacuanha used, the treatment consisting of monsonia in from two to four drachm doses every four or six hours. In a few of the later cases the action of the monsonia was supplemented by pilula plumbi cum opio, as, for instance, Case 88; but it is interesting to note in this case that the patient had previously to coming under treatment been taking both tincture of opium in full doses and pilula plumbi cum opio, and that in spite of the exhibition of these drugs the symptoms had become steadily worse, showing that the pilula plumbi cum opio alone was ineffectual as a cure. My reasons for adding pilula plumbi cum opio to the treatment in some of the later cases was that the specimens of monsonia from which the tincture I was using was made had been gathered nearly three years previously and appeared to be losing to some extent its activity. It is a recognised fact among pharmacists that some drugs, especially when kept in the dry state in hot climates, steadily deteriorate in quality, and in my experiments I have found that this was apparently the case with monsonia. The average number of days that a patient was under treatment was 2·3, which is certainly far below the average of any statistics which I have been able to consult under any other form of treatment.

Although, according to some of the Indian authorities, the records of the treatment of acute dysentery with ipecacuanha show almost equally good results, monsonia has one great advantage in that it requires no special precautions and can be taken by the patient just as any other drug without the necessity even of remaining in bed. Secondly, chronic dysentery, on the other hand, has not up to the present time proved amenable to any form of treatment, and has been hitherto looked upon as incurable and very frequently fatal, but the preceding records go far to prove that monsonia is as efficacious in the treatment of chronic as in that of acute dysentery. Out of the 100 cases I have reported ten were chronic, and of these nine made complete recoveries, and were under treatment for 8·1 days on the average. The one exception was Case 85; even in this case the dysentery was cured, but the constitution was so exhausted by the long illness previous to treatment that the child succumbed to cancrum oris. Seven of the chronic cases recorded as being cured were under observation for periods varying from one to four years, no relapses occurring. One case was lost sight of after six months, during which time the patient had no recurrence. The remaining case (No. 93) was the only one to my knowledge in which a relapse occurred; this was due, in my opinion, to the tincture of monsonia having lost some of its qualities, the plants from which it was made having been kept too long. This case was soon cured, however, by a fresh infusion of the drug made from plants collected on the patient's farm. The monsoniæ belong to the order Geraniaceæ, of which they form a genus. A great number of varieties are found in Southern Africa. The plants I have used come under the varieties Monsonia ovata and Monsonia Burkei. Several species are known to have astringent properties due to the tannic acid which they contain, chiefly in the roots. Their action as astringents is, however, weak, and I do not think that the results obtained by the preparations I have used in dysentery were at all due to their astringent properties. This conclusion is borne out by the fact that the drug appears to have very little effect on ordinary diarrhœa and also that the preparations made from the dried flowering plant without the root were in dysentery quite as effective as, if not more so than, those in which the root was used, and in which certainly a large proportion of tannic acid was present.

Judging from the number of cases which I have now

Hosted by Google

treated I feel convinced that the plant has a specific action on the poison of dysentery apart from any mere astringent properties. Whatever the active principle of the drug may be it appears to have a soothing influence on other forms of intra-abdominal irritation to the lower nerve centres. This was shown by the distinct and rapid relief it gave in about six cases in which I tried it in pelvic pain due to old inflammatory peri-uterine lesions. In each of these cases the relief was much greater than that obtained by opium or its alkaloids. These facts lead me to conclude that the effect of the drug on dysenteric symptoms is partly due to its soothing action on some of the lower nerve centres and partly to the peculiar healing influence which it exerts on ulcers of the intestinal tract. In the beginning of 1896 through not being able to obtain specimens of the plant I was obliged to return to the use of pharmacopœial drugs. This was unfortunate, as during the Matabele rising from March to July, 1896, an epidemic of dysentery occurred at Bulawayo, which would have afforded me very valuable materials for further researches with regard to the action and the peculiar properties of the drug. Though so far nonplussed I was still able to cope successfully with acute cases of dysentery, and it may be of general interest to give some account of the treatment pursued. One of the first cases which came under treatment was that of a child, four years of age, suffering from acute dysentery. I ordered four grains of pulvis ipecacuanhæ compositus with four grains of pulvis kino compositus every six hours and an enema of warm water twice a day. The child appeared to be all right the next day, but two days after the mother sent for me again, when the dysentery was as bad as ever and prolapse of the rectum was commencing. The powders seemed to have no effect. I ordered the enema to be continued and three grains of phenacetin to be added to the powders. The result was excellent, the child rapidly recovered and no relapse occurred. Most of the subsequent cases occurring in this outbreak were of a very acute form, often associated with a good deal of vomiting and sometimes high temperature. The treatment, briefly stated, was as follows. A mixture containing one and a half drachms of liquor bismuthi, one minim of acidum hydrocyanicum dilutum, ten minims of liquor morphiæ hydrochloratis and water to one ounce was given every four hours in cases where there was much vomiting. Ten minutes after each dose of the mixture a powder containing ten grains of pulvis ipecacuanhæ compositus, ten grains of pulvis kino compositus, and five grains of phenacetin was administered. In other cases ten grains of bismuthi sub-nitras was given before or with the powders. Where much fever was present a powder containing eight grains of quinine with eight grains of phenacetin was given night and morning. In cases in which the attack was of more than forty-eight hours' standing an enema of about two quarts of warm water with a little Condy's fluid was given. The patients were not kept in bed except in severe cases. Meat diet was strictly forbidden. Most authorities incline to the opinion that astringents and full doses of opium are not only useless but do much harm in the acute phase of the disease, and I think the foregoing powder would certainly come under that condemnation. The results, however, were extremely satisfactory in all the acute cases, which numbered somewhere about forty. I attribute their success to the addition of the phenacetin and also to the administration of the enemas. With regard to phenacetin, the *rationale* of its action in dysentery is somewhat similar to that of ipecacuanha. Dr. Ewart attempted to explain the action of the latter in the following terms:—"In large doses it stops inflammatory action, augments the alvine secretions from œsophagus to rectum, increases the flow of bile and pancreatic juice, purges without irritating, lessens peristaltic action, produces rest, restrains tormina and tenesmus, promotes diaphoresis, restores the balance of the portal circulation, is a direct sedative to cardiac action, and acts on the stomach and duodenum, pancreas, liver, and small intestines, and on the glands of the large intestine."

Although this statement is somewhat vague it is in the main, perhaps, as correct a representation of the action of ipecacuanha, and still more so of such powerful diaphoretics as phenacetin, as in the present state of our knowledge can be given. Consequently it acts as a corrective to the astringent qualities of kino and to the tendency which opium has to check the natural secretions in the intestines, which latter it is most important to encourage. Both the astringent action of the kino and the sedative action of the opium are very necessary in relieving the dysenteric symptoms, provided any deleterious action is guarded against. In order to explain the beneficial effects of large enemata in the treatment of dysentery it will be essential to draw attention to a very important point in the pathology of the disease and one which appears to have been almost entirely overlooked. After the first day or two in an acute attack of dysentery, and commonly in chronic cases, the small intestines are loaded with fæces. The way in which this condition is brought about appears to be as follows. An acute attack commences with diarrhœa which is at first feculent in quality; the stools gradually change from feculence to mucus and blood. This change takes place any time within the first forty-eight hours. From this stage onward, perhaps for days, no fæcal matter is passed. What apparently happens is that the dysenteric ulcers in the large intestine cause spasmodic contraction about the ileo-cæcal valve, which entirely shuts off the small intestine from communication with the large, thus preventing any chance of irritation to the dysenteric ulcers from fæcal matter. An exactly similar condition is seen in inflammation of the cornea, where the eyelids are spasmodically contracted as a natural protection against the irritation of light. This condition having been once induced it is self-evident that to give heavy doses of opium and astringents, without at the same time endeavouring to clear the small intestines of fæcal matter, would only tend to aggravate the disease. The fæcal matter continues to accumulate in the small intestine, increases the tendency to tormina and tenesmus, and adds fæcal poisoning to the other symptoms. This latter accounts, I think, to a large extent for the very rapid exhaustion which occurs in cases which are left untreated. It is for these reasons that large doses of opium and astringents have been so universally condemned; but I contend that if given with proper precautions opium and astringents are of decided benefit in the acute stages. I now make it a rule to inquire on first seeing a patient whether any fæces have been passed during the last twenty-four hours, and unless the attack is quite recent I invariably find that such has not been the case. I then order an enema of two or three pints of warm water with a little Condy's fluid in it. The patient as a rule passes a large quantity of fæcal matter and experiences a great feeling of relief, the tenesmus disappearing for the time being. Very weak solutions of any disinfectant are applicable, with the one exception of bichloride of mercury; this drug in the weakest solutions causes acute pain. In some cases, where the ulcer is low down in the rectum, the sphincter ani will be found to be paralysed temporarily. It is then impossible to evacuate the small intestine by means of enemata. In these cases it is necessary to give castor oil. In the subsequent treatment of dysentery, provided the tendency of the small intestine to become blocked is counteracted, no harm can result from the use of opium and astringents, combined with such diaphoretics as ipecacuanha and phenacetin; and judging from my experience in a large number of cases I feel convinced that they materially assist in the cure of the disease.

Birmingham.

ACUTE PEMPHIGUS.

BY MAURICE EDEN PAUL, M.D. BRUX., M.R.C.S. ENG., L.R.C.P. LOND.

IN THE LANCET of Oct. 31st, 1896, Dr. James Priestley described an interesting case of acute bullous eruption on an erythematous base, attended by severe febrile symptoms and ending fatally. He regarded the case as almost, if not quite, unique, but asked for opinions from those who have had experience of like cases. In the latter half of 1890, when I was in residence at the London Hospital as house physician to the late Dr. H. G. Sutton, I saw a very similar case. Notes are not now accessible to me and I can describe the case from memory only, but fuller particulars could readily be obtained from the records of the hospital. The patient was a middle-aged woman of a full habit of body. She was suddenly attacked with febrile symptoms attendant on the outbreak of a violent dermatitis. The skin over large areas of the trunk and extremities was bright red and raised, presenting, like erysipelas, a firm edge at the

Hosted by Google

junction of the inflamed and the healthy parts. On the surface of the inflamed areas of skin bullæ, from half an inch to one and a half inches in diameter, were freely sprinkled. In places these bullæ were confluent. It will be observed that this case differs from Dr. Priestley's in the presence of infiltration of the skin in addition to the erythema. That, however, the disease was not erysipelas was shown by the simultaneous appearance of the dermatitis in such wide areas. Moreover, diffused acute erysipelas would almost certainly have killed the patient in a day or two. I cannot recall whether there was or not faucial inflammation. Dr. Sutton was not attending the hospital when the patient was admitted, so at my request Dr. Stephen Mackenzie kindly saw the case. He said that it was anomalous, but that if he were compelled to give it a name he should call it "acute pemphigus." The patient was severely, even dangerously, ill for a time, but, as far as I can remember, made a good recovery in about ten days. The cause of the illness remained obscure.

Surely cases of this kind, though rare, are well recognised. Whitehouse, in the article on Bullous Affections in "Twentieth Century Practice," describes it as "pemphigus acutus," an eruption of bullæ on an erythematous base, with febrile symptoms and pharyngitis. He says, however, that the bullæ never exceed half an inch in size. In Dr. Priestley's case "the smallest bullæ were as large as a hen's egg"; and in the case I have described the bullæ were also, unless my memory plays me false, far larger than those mentioned by Whitehouse. But when the line that separates a "vesicle" from a "bulla" has once been passed, variation in size depends probably on individual peculiarities of skin and on the intensity of the inflammatory process, and cannot be regarded as specific. Again, the only difference between pemphigus acutus neonatorum and the pemphigus acutus of older children and of adults, appears to lie in the absence in the former case of pharyngitis. There is the same acute outbreak of large bullæ on an erythematous base, with fever and prostration. The absence of pharyngitis in pemphigus acutus neonatorum may be due to the fact that infants appear to be exempt from catarrhal inflammation of the pharyngo tonsillar region. Even in the case of the powerful poisons of syphilis and diphtheria, the stress of the inflammation falls in infants on the nasal and laryngeal mucous membranes, while the fauces are slightly if at all affected. Catarrhal pharyngitis I have never seen in a child under two years of age. The cause of these acute bullous eruptions remains undiscovered, and I have no light to shed on the subject. My excuse for writing this paper consists in my desire to bring before the profession the case already described and also one much more singular that came under my notice three years ago.

Case of acute pemphigus and acute eczema of the face in an infant, the two diseases being intercurrent, but independent in course.—The patient was a female child aged two months. Acute eczema of the face and hairy scalp of ordinary type began on Jan. 28th, 1894. On Feb. 4th bullæ appeared in the groins, then on the neck, and then on the upper part of chest and back, the crop in these regions occupying three days in its development. The blebs were about half an inch in diameter and in many places confluent. Three fingers of the right hand were entirely denuded of epidermis on the morning of the 7th. Up to this time the general condition had been good, but further blebs appeared, so that on the 9th the eruption was almost universal except on the legs, head, and face; collapse set in, and the infant was kept alive only by the free exhibition of brandy. The blebs being closely set and rupturing early, the appearance was that of an acutely inflamed skin with the epidermis hanging in shreds and patches, as in an extensive burn of the second degree. On the evening of the 9th the child began to recover strength, but moderate fever continued till the 12th. By the 14th the skin was soundly healed. Meantime, on the face, on which no bullæ had appeared, the eczema had run its ordinary course. By the 14th the period of active secretion and crust formation was over; but sub-acute discrete papules and vesicles continued to appear for more than a month longer, the child's general health remaining good all the time. The child is now, at three years of age, in excellent health. Such an example of two specifically distinct skin diseases running an independent, but a simultaneous, course in the same patient is, I think, sufficiently rare to deserve being placed on record. The sanitary surroundings and the feeding (artificial) of the child at the time of the illness were all that could be desired, and no cause could be discovered. The case was an isolated one in my practice. The child's father had suffered from acute eczema in infancy; again and severely at the age of eighteen years; and is now never free from chronic eczema in winter. This fact may interest those who believe in the existence of a "dartrous diathesis."

Nagasaki, Japan.

TREATMENT OF MALIGNANT TUMOURS BY MIXED TOXINS.

BY HUGHES REID DAVIES, M.R.C.S. ENG., L.R.C.P. LOND.

IN an annotation in THE LANCET of Dec. 5th, 1896, there is a record of a meeting of the Johns Hopkins Medical Society, at which Dr. Coley read the results of his treatment of 160 cases of malignant tumour by subcutaneous injections of the toxins of erysipelas and bacillus prodigiosus. Dr. Coley's perseverance and patient research should merit respectful attention, even though his resulting success be so limited. I should like to draw attention to an extract from my case-book on "Coley's fluid."

A stout Jewess, married, aged fifty-three years, with a strong carcinomatous family history, consulted me in 1893. At the axillary border of the right mamma, distinct from the gland tissue, I found a hard, clearly defined, freely moveable mass the size of a walnut, over which the skin was unbroken. I offered to excise the growth, but consent was refused. In October, 1895, I was again consulted and noted that the tumour was distinctly nodular, the size of a hen's egg, attached to the skin, and moveable with difficulty. The right mamma was much swollen. The cutaneous coverings of the axillary half of the mamma were hard and œdematous. The skin over the tumour was unbroken. The axillary and clavicular gland were implicated. On Oct. 3rd Mr. F. S. Eve kindly saw the case with me. We decided not to operate for many reasons, among which were: the duration of the disease from my first diagnosis in 1893; the presence of an adherent, ill-defined, infiltrating mass in the axilla extending under the pectoral muscles; the condition of the skin; and the strong objection of the patient's friends to any operation. The patient herself also had a horror of any attempt at surgical interference, yet craved that something might be done. As a last resource, and to satisfy the patient, subcutanous injections of Coley's fluid were commenced. On Nov. 22nd a hypodermic injection of one minim of Coley's fluid was administered about one inch from the tumour on the sternal side. There was no appreciable reaction beyond a slight blush round the tumour. On the 25th two minims of a weaker solution (equal to one minim of the previous stronger solution) were injected with no appreciable result. On the 27th two minims were injected and resulted in rigors, followed by about one inch of slight circumferential blushing lasting twenty-four hours. The patient was mentally but not physically upset. The temperature was 101° F. and the pulse was 90. The œdema of the skin was certainly less On Dec. 3rd three minims were administered and followed by slight rigors. On the 6th five minims were given, which produced strong rigors, vomiting, and diarrhœa (lasting two hours) within half-an-hour of the injection, which was well into the base of the tumour and not into the neighbouring skin. Four hours after the injection the temperature was 102 5° and the pulse was 140; there was no body rash, but a broad circumferential blush and axillary gland tenderness. There was great bodily and mental distress. Following this there were debility, loss of appetite, a daily temperature of from 100° to 101°, with a pulse of from 90 to 100, until the 14th, when another injection of four minims into the base of the tumour was given, from which there was no reaction. By this time there was not much increase in the size of the base, but the fungations were more expansive. The tumour was freely moveable. The œdema of the mamma and of the axillary folds was less. There was no inflammation or suppuration at the seat of the injections. There was no body rash and no wasting, but there were slight occasional hæmorrhages and free serous discharge from the fungating surface. On the 20th the fungating mass was sloughing

Hosted by Google

centrally, leaving a large cup-like cavity surrounded by large unequal fungations. The mamma was larger and harder. Owing to objections from the patient no hypodermic injection had been given since Dec. 14th. On the 23rd three minims were injected but no reaction followed. On Jan. 11th, 1896, the tumour centrally had sloughed almost flush with the thorax. There was marginal increase. Four minims of fresh Coley's fluid were injected into the marginal fungations, which produced a vigorous reaction in half an hour, with rigors and vomiting, followed by stupor and difficult locomotion, and succeeded by a deep sleep lasting all night. From this date to March 19th the injections were fairly regular at intervals of a few days. There was free serous discharge from the tumour, especially from the central cavity. The marginal growths were thinning perceptibly. Rigors, and often retching or vomiting, nearly always followed the injections. The patient was daily losing weight and strength, and the growth was slowly but steadily increasing in size, it then measuring four inches by three inches. An eczematous, patchy condition of the skin appeared on the forehead, eyelids, and extensor surfaces of the knees and elbows, with exfoliation. The skin of the fingers and palms cracked and peeled. At this stage, as no appreciable benefit had been derived, the injections were stayed.

On Dec. 7th, 1896, the tumour was found to extend from the angle of the right scapula to the axillary half of the right mamma, and above from the apex of the axilla to a line drawn from the lower border of the mamma to the inferior angle of the scapula. The pectorales muscles were pushed forward by the growth; the right arm was twice its normal size from œdema, and the clavicular glands were markedly increased in size and hardness. The mamma itself was badly infiltrated and partly sloughing. Mitigation of the agonising pain and sleeplessness experienced by the patient was derived from morphia pills, of which she daily took up to two grains. The local treatment throughout was an endeavour to keep the fungating masses dry, sweet, and clean by various powders and antiseptic washes.

On Dec. 23rd the patient became semi-comatose and, without regaining consciousness, died on Dec. 27th, 1896. The usual Jewish objections to post-mortem examination prevented me following the case further; but external abdominal examination showed that there was immense hepatic enlargement, the lower margin almost reaching the iliac crest.

Remarks.—The value of Coley's fluid, as gathered from the foregoing notes, has been, in this case of carcinoma, I fear, practically *nil*. True, in the early stage of the disease I fancied the rate of growth was checked and the fœtor of the discharge lessened, but the terribly alarming reactions after injection, and the final skin effects, as noted, induced me to desist from a further course of treatment.

Bow, E.

SOME REMARKS ON PLAGUE.

BY J. A. LOWSON, M.B., C.M. EDIN.

A FEW remarks on some plague questions may not be out of place at a time when Europe is threatened with invasion by an old enemy, and especially as a late paper on the subject—viz., that by Dr. Cantlie before the Epidemiological Society on Dec. 18th, 1896—contains inaccuracies regarding the Hong-Kong epidemic as well as opinions which are not shared by several of those whose experience of the disease has been very much greater than his. Full treatment of these subjects can scarcely be gone into, as considerations of time and space do not permit at present.

1. *Nomenclature.*

Any change in the nomenclature of the disease is greatly to be deprecated; there is really no necessity for it. In Hong-Kong those of us who were constantly describing the disease to medical visitors had occasion to call it a malignant polyadenitis some time before Dr. Cantlie ever saw a case. It will be time to change the name when we find that plague includes two or more diseases, as typhus fever did in days gone by. At present, however, there seems to be little danger of the name "malignant polyadenitis" taking root; one might as well apply it to syphilis as to plague.

2. *Distribution.*

The present known limits of plague have not been correctly laid down by Dr. Cantlie. I have very little doubt myself that plague has made its way over Europe, Asia, and Africa in past days. In the course of desultory reading I came to the conclusion that the East Coast of Africa at least had suffered from the disease further south than a limit of nineteen degrees north, but without medical authority at hand refrained from mentioning this at the Epidemiological Society's meeting when plague was discussed. Since that time I find that plague is well known in Equatorial Africa, and through the courtesy of Mr. Peter Rattray of Dundee, lately in Uganda, some interesting details can be given. The disease in the Uganda district is known as "kaumpuli" and is well known there. In a dictionary edited by Pilkington and printed by the Church Missionary Society in 1892 the definition of this word is given thus:—"The plague—a disease attended generally by a swelling of the glands, pain in the chest, very prevalent after the rains. Treatment: Blisters on the swollen parts and an emetic is the most successful." I understand Captain Ashburnham of the Rifle Brigade nursed a European through the disease out there. I hope to get further information on the African distribution of the disease. When a native is attacked the whole tribe remove to another district at once—sound policy easily carried out because of its inexpensive character. Uganda is practically on the Equator, and although almost 4000 feet above the level of the sea the mean temperature should be nearer 90° than 80° F. The usual afternoon temperature in the shade is about 98° in the dry season, slightly less in the rainy season. This surely does away with Dr. Cantlie's limits and the ingenious suggestion of Dr. Payne that the isothermal line of 78° may stop the march of the disease. If the disease is well known in the centre of Africa it must have found its way there; and I will not be surprised, now that attention has been directed to the subject, to hear that it is met with in other tracts of Africa. It seems peculiar that Stanley and other explorers have nothing to say on the subject, the information I had previous to Mr. Rattray's being founded on missionary lay reports on the disease.

In Singapore in the latter end of 1895 or early in 1896 the death-rate was abnormally high (from sixty to seventy-five per mille per annum) for several weeks, and some malignant disease was presumably "hanging around." The authorities there, however, reported that no plague existed. In 1896 three cases of plague were landed in Hong-Kong from ships arriving from Singapore, and although two cases could be explained away by long periods of incubation or other loop-hole, one case—that of an Indian servant on a Calcutta liner—leads me to conclude that he must have been infected in Singapore. He was perfectly well when he left Calcutta and no swellings of any kind whatever were present prior to his arrival at Singapore, yet after being on shore in Singapore he became severely ill in three days, typical plague glands formed, and he was landed at Hong-Kong to die. Even the medical officer of health who saw the gland and had had previous plague experience did not think it was plague at first, but it was an undoubted and typical case. From the inquiries made of the man I could not trace any other source of infection, such as by fomites, &c., on the ship. Calcutta at that time was not infected, so, if my conclusion be right, Singapore is another equatorial spot to be added to the geography of plague colonies. I trust further explanation will be forthcoming. So far, if it has been in Singapore it has not done much damage.

The evidence regarding Uganda, however, must convince us that plague will march and flourish wherever it is carried and finds a suitable pabulum—irrespectively of the ordinary temperatures we find on this earth.

3. *Pestis Minor and Pestis Ambulans.*

It is to be hoped these two terms will be kept distinct when further discussion occurs. Pestis minor is that bubonic disease which occurs (?) before an outbreak of plague, whilst pestis ambulans is the designation applied to glandular enlargements occurring during or after an epidemic which may probably be due to a less potent infecting power.

Pestis minor.—The Hong-Kong experience in this respect

Hosted by Google

requires notice. Dr. Cantlie said in his paper that all his ideas on the subject had been changed in a few days owing to the reputed discovery in the blood of patients suffering from buboes in Calcutta of a bacillus similar to the plague bacillus. Since 1889 Dr. Atkinson has placed the venereal wards especially of the Government Civil Hospital in my hands, and the records of excision and scraping of glands in that institution given by Dr. Cantlie cannot enter a plague report at all. Before the Hong-Kong and China Branch of the British Medical Association I read a paper in 1893 entitled, "On Venereal Disease in the Far East and the Repeal of the Contagious Diseases Act," and stated that all these cases of inguinal bubo which I had operated on were venereal in origin, in most cases due to a preceding chancre, in some cases due to gonorrhœa; in every case an antecedent venereal history was obtained. I think it must have been at this same meeting that Dr. Cantlie gave the definition of the bubo published in THE LANCET of Jan. 2nd, 1897. The majority of the members at that time gave a similar experience to that obtained at the Government Civil Hospital, and if further inquiries had been carried out perhaps Dr. Cantlie might have modified his statements on these cases, many of which probably were of that kind of patient who did not want to have venereal disease as a cause of absence from work. It was surely remarkable that they all occurred in the inguinal glands, more remarkable still that they all occured in men. No comparison could be drawn between the years I have mentioned and those previous, as radical treatment such as excision at least was seldom, if ever, attempted. I have been informed by some of the older practitioners of the East that the same type of bubo has been in evidence for as long as they can remember in China. I have seen very few of the non-venereal buboes mentioned by Dr. Manson, and in all there was some cause for the enlargement such as continued irritation from morphia injection, old injury, elephantiasis, or other similar mischief. In one case excessive copulation seemed to be the cause of an inguinal bubo, but after a few days on Easton's Syrup a slight discharge from the penis took place, which proved to be the remains of an old gonorrhœa. A peculiar form of lymphangitis appeared in the garrison of Port Hamilton in 1886-87 and was reported by Surgeon A. J. Wildey, R.N., in the Transactions of the Hong-Kong Medical Society published in 1889. Here there was a lymphatic disease of a somewhat epidemic character, but it cannot be said it was the forerunner of plague or in any way associated with it.

The children's epidemic glandular disease related by Dr. Cantlie in 1891 was certainly peculiar, but he forgets to mention that at the time he was fully convinced it was mumps. I saw several cases of true mumps about that time, but knew nothing of Dr. Cantlie's cases until he read his paper before the British Medical Association, Hong-Kong branch. It was singular that no adults were affected, and although a close watch was kept in the Government Civil Hospital afterwards no cases were ever seen by the medical officers there. Godding's cases coming after the plague, if related to that disease at all, should be treated under the heading of pestis ambulans. They were very like those narrated by Surgeon A. J. Wildey, R.N., and the danger of plague on board men-of-war may be the next scare for the Admiralty.

I contend that the Hong-Kong cases mentioned above have no relation to plague and cannot be classed as pestis minor—that bubonic plague in its severe type was introduced straight into Hong-Kong without any mongrel form intervening. In 1893, when these buboes were discussed, I mentioned that, not to be behind Dr. Cantlie, I hoped to discover the bacillus bubonicus Lowsonii, but have to confess to having failed up to the present moment. I have asked several medical men in America to keep watch on their bubo cases, many of which show the same characteristics which have been noted in the East—their results may be expected presently. The Calcutta cases should be "thrashed out" by the medical men there. The reports already received give good grounds for scepticism.

The reports of the Russian outbreak in 1877-79 leave no doubt that Dr. Döppner saw some cases which at present have the best claim to be classed as pestis minor; but what a different description to those of the Far East. "They had abscesses of the lymphatic glands either of the groin or the armpit which were suppurating freely." Again: "It was marked by a period of feverishness occasionally extending to a fortnight, but usually of a shorter duration, followed by the development of buboes in the submaxillary, axillary, and crural regions, *but most frequently in the submaxillary region.*" If my memory is correct none of Dr. Cantlie's children's cases suppurated; they resolved, as the usual parotiditis caused by mumps in this country does. In most hospitals in Britain a certain number of lymphatic abscesses occur every year, and it has been the same in Hong-Kong. Mr. Rattray informs me that in Uganda many natives came to him with swollen glands and said they had "kaumpuli," but that in every case he found some ordinary cause for the condition.

I trust these remarks will remove any false impression Dr. Cantlie's remarks may have given regarding the subject of pestis minor in Hong-Kong in 1894.

Pestis ambulans.—After the 1894 outbreak it was only natural that some glandular cases should occur where there was doubt in diagnosis, and in several such I examined microscopically the blood and gland "juice" without finding a trace of the plague bacillus. I made no culture experiments. In most acute infectious diseases a minor infecting power has been proved—cholera, influenza, and diphtheria being common examples; but in plague so far I have not met it, unless a slightly greater percentage of recoveries towards the end of an epidemic is attributable to this cause. A very careful history has to be got before ambulatory plague can sometimes be excluded, and so far I do not know if the plague bacillus has ever been found in pestis ambulans. It seems possible that a small amount of the toxin may be somehow absorbed by the body to cause slight glandular enlargement without the necessary entrance of bacilli, as the products of the bacilli may hang about a neighbourhood long after all bacilli are dead. One case sent in by Dr. Cantlie will illustrate the difficulty of diagnosis sometimes met with. A Parsee was admitted with slight elevation of temperature and enlargement of glands in the left femoral region. Preliminary examination of blood was negative and no cause could be found for the enlargement until a nocturnal specimen of blood showed we were dealing with a case of filaria sanguinis hominis. This was a purely accidental occurrence—the examination of a 9 P.M. specimen of blood; but for this we might have had this case puzzling us still for a diagnosis. The only case during the epidemic—or rather immediately afterwards—which was really doubtful was that of one of our nurses whom I was requested to see after she had been ailing for some time with lymphatic inflammation of the right leg and femoral lymphadenitis. Four or five weeks previously she had had some pain in the groin simultaneously with pain extending down the lymphatics of the leg to the knee, and it was only when the lymphangitis was well marked down almost to the toes that she complained and took to bed. For several reasons it was deemed unwise to make a puncture in the gland, so no microscopical examination was made. Recurrent attacks of lymphangitis followed, with occasional enlargement of the gland, such as is seen sometimes in any large hospital, and the conclusion was come to that it was not due to plague infection. This is the only case seen which has been left in doubt. During 1895 cases of ambulatory plague were still looked for carefully, but none turned up which could be classed under that heading—in fact, the so-called sporadic cases showed no lessening of virulence, with the result that every case died if my memory serves me right. In Swatow several cases occurred, so I am informed, but of these more evidence is required yet. While on this subject it is right to mention that many mistakes have been made by competent men when examining blood or bubonic tissue for the plague bacilli, and it requires some time for even a man who has done some laboratory work to be sure of the correctness of his examination.

(4) *Infection. (a) Method of Leaving the Body; (b) Mode of Infection; and (c) Carriage and Spread of Infection.*

(a) Method of leaving the body.—One certain but infrequent channel is by the discharge from buboes. The bacilli are numerous in such discharge, and even after it becomes purulent some days elapse as a rule before the bacilli disappear and the infecting power is lost. This loss of infecting power will explain why the experiments which have heretofore been made by inoculating man and animals have failed, and the statement has consequently been made that the discharge from buboes was not infective. After some days' suppuration the pus has no more infecting power than that from a simple ulcer. The reason why this channel of exit is infrequent is that death generally supervenes before any vent to the discharge is made or required. Out of about

Hosted by Google

2300 cases seen in the Hong-Kong Chinese hospitals certainly not fifty buboes suppurated and burst, whilst in Macao and Canton I only noticed other two such cases amongst large numbers of plague-affected patients. The fæces are infective. The most complete experiments on this subject were made by Staff-Surgeon Wilm, who was working with us in Hong-Kong.[1] In every case he experimented on culture from a plague patient's fæces gave positive results as to the presence of the plague germ. In cases where albuminuria and casts were found bacilli were also present in the urine. The sputum almost always contains them, as also the fur on the tongue. At present there is no evidence to show that the milk is infective. I doubt it, as many children who were suckled by their plague-stricken mothers were left on our hands in hospital. Still, it is possible that such children were able to resist infection by the alimentary tract or mouth inoculation. No bacteriological experiments were made. The bacilli have so far not been found in the sweat secretion and I do not think in pure sweat they will be obtained. All culture experiments so far have failed. I believe there is little or no danger of infection by the breath of a plague patient. In Hong-Kong, had this danger been great, certainly more deaths would have occurred amongst those occupied in plague work. In the house-to-house visitation party who went round twice daily and entered the most infective houses in the city no one took the disease. Their duties only necessitated examination of the inmates of a house and their removal when suffering from plague, with a minimum of interference as far as movement of furniture or dirt was concerned. At the height of the epidemic these men spent the best part of two hours twice daily in the worst infected houses in the city. I certainly do not agree with the view that prolonged exposure to, and respiration of, "plague atmosphere" is necessary to get plague. A lengthened exposure only adds to the possibilities of a man getting it; he might get it from merely looking in at the door and getting a whiff of dust from the floor blown into his face; it is plague dust and dirt which are the infecting agents in houses. The cleansing squad of soldiers suffered, however—those who had to remove the dirt after stirring it up—and these only suffered when a preliminary disinfection was not carried out. After primary disinfection had been thoroughly set going none of these soldiers took plague. Several of the sanitary board's men who drove the dirt and refuse and shovelled it on to the fires on the Praga died, but, in contrast to this, notice how the attendants in hospitals fared. During the first ten days of the epidemic the hospital ship *Hygeia* was overcrowded (considering the hot, still atmosphere in the harbour), and the lower deck especially threatened to be dangerous, the smell of patients lying in dirty clothing being sickening and causing frequent emesis amongst those looking after their welfare, reduced in numbers and unable to get through all their bathing duties on account of many of the "boys" having fled. In this "hole" not one of these remaining attendants took the disease, although they were frequently fourteen hours on duty there. A Chinese hospital (the old glass works) was opened shortly after, and in forty-eight hours the building was crowded with dead and dying, and the condition of affairs under Chinese management grew most alarming. Here were wards full of patients looked after by Chinese attendants, who religiously kept all windows and doors closed whenever a European's back was turned, and who often slept in the same rooms as their patients, only separated from them by a partition extending half way up to the ceiling. Not one of these got plague, although they were breathing as thick a "plague atmosphere" as one could desire. Even some days after, when free disinfection of the floors took place every morning when being swept, the atmosphere during the night was indescribably bad. The deaths of hospital attendants in 1894 were only two in number in Hong-Kong. The first to contract the disease was a Eurasian Roman Catholic sister at work in the Alice Memorial Matshed Hospital, the cleanliness of which was undoubted; but the sister having had no previous experience of nursing it is probable that some indiscretion was the cause of infection. Incidentally I would remark that the most stringent instructions to be careful should be given to all attendants and any carelessness punished at once—even by dismissal if other attendants can be had. The other case was that of an Amah in the Chinese hospital (the new abattoirs), where hygiene was perfect so far as the building was concerned. Here, again, there was ignorance of nursing, not to mention the fact that the woman had to do the washing of patients' bedclothes, &c., in addition. At a Chinese hospital outside Hong-Kong one attendant took the plague and died. This hospital was meagrely supplied with lime as a disinfectant. At a large hospital I visited in Canton after the plague had been raging there for three months none of the attendants so far had taken the disease although they lived practically with the patients—some of the attendants' friends actually sleeping in the same small room. In this case, however, actual contact with the patient was rare, as the latter were allowed to die in their old clothes and were only occasionally supplied with tea or medicine (?) out of a pot or Chinese bowl. This hospital used no disinfectants. The walls of the small rooms had been whitewashed before the epidemic began and the floors were simply swept up after each patient died and a new mat was placed upon the bed board, the old one being generally destroyed. I contend that in the case of the lower deck of the *Hygeia* (for some days, at least), in the Glassworks Hospital and the Canton Hospital the condition of the atmosphere as far as being laden with the expired air of plague patients could not have been worse; the attendants had every opportunity, from length of time employed, of inhaling it for hours on end, yet none took it, and one is forced to believe that the mere expired air of a plague patient cannot have much, if any, potency. The infection of plague in this respect I liken to phthisis, the sputum here again conveying the infecting matter. Further, the majority of houses in Hong-Kong consist of a ground-floor and first-floor, in many cases a second-floor, and occasionally a basement. These floors are connected by a wooden stair inside the house shut off from the dwelling parts by a badly put together wooden partition, in some cases not reaching up to the ceiling. Now the atmosphere of this house is practically the same all through, yet often the inhabitants of single floors would be swept away and the others escape scot free. These floors were attacked indiscriminately—the first-floor or second-floor seeming to be attacked with greater regularity than the ground-floor, probably because the last was more exposed to the fresh air and sunlight and had a larger exit for refuse. This impartiality in attack of floors is also a strong point against those who pin so much faith to the theory that the soil originates or harbours the disease and that the order of attack depends on the distance an animal's or man's mouth is above the ground. This was especially the case in 1894, and I do not think the 1896 experience has been much different. In the latter year many isolated cases occurred in houses, but the disease got no further owing to excellent organisation, early detection of cases, and immediate disinfection. The term "house epidemic" has frequently been made use of in previous plague history, but this ought now to make way for "floor" or "flat epidemic." Of course, it may happen that all floors in some houses may be infected at the same time, but from what I have already said it is probably unusual.

(*b*) *Mode of infection.*—"Infection may take place by inoculation, inspiration, or introduction into the stomach."[2] The preponderating method will vary in different epidemics and will depend on the opportunities presented. Rabbits, when inoculated by an incision in the abdomen, generally present appearances of reaction—inflammation and œdema—round the wound. When inoculated in the leg such reaction is sometimes absent. Lymphangitis in man may or may not occur early in the disease, and even if present may give no external evidence of its presence. Some cases may be instructive.

CASE 1.—Professor Aoyama of Tokyo: "On June 28th, at a dinner given by the Japanese doctors to several of the Hong-Kong medical gentlemen connected with the plague, Professor Aoyama's temperature was 101·6° F. He slept well during that night. On the morning of the 29th Dr. Cantlie saw him and found him suffering from what he supposed to be the results of a dissection wound. At 5.30 P.M. he was seen by Dr. Molyneux and myself, and the case being immediately diagnosed as plague he was removed to the *Hygeia*. From the evidence which we procured it seems that on June 22nd or 23rd, whilst making a post-mortem examination he scratched the left third finger on the posterior and ulnar aspect of the first phalangeal joint.

[1] See Report to the Hong-Kong Government on the subject, 1896.

[2] Medical Report on Bubonic Plague to the Hong-Kong Government by James A. Lowson.

Hosted by Google

On June 27th he again scratched himself on the end of the right thumb. When removed to the *Hygeia* he had a temperatare of 105°; had a bubo in the left axilla without lymphangitis; had a well-marked lymphangitis of the right arm extending up to the level of the middle of the humerus." Here there was no lymphangitis at first in what I took to be the plague-infected arm, but it was only non-apparent, as it appeared later, and its intensity can be gauged by the fact that over twenty incisions had to be made in it. Professor Aoyama's own statement is as follows (translated from the German): "On June 28th, after having finished a dissection, I took my meal about half past two and did not enjoy it. After the meal I went upstairs, when at certain movements of the arm I felt a slight pain in the left armpit, and on feeling with my finger I found some slightly enlarged glands present. In the evening I felt very ill, depressed, and languid, burning hot along the whole of the back, whilst the thermometer showed normal temperature. As Mr. Kitasato and I had invited guests that evening I was present at supper. I had no appetite and felt so weak and languid that I often wished to withdraw. At half-past eleven I hurried to my room, when I found my temperature was 39·5° C. I took 1 gramme of quinine and slept well. Next morning I awoke and noticed on the ulnar side of the left ring-finger a small, whitish-yellow blister, and thence along the back of the hand a red line. From this time I remembered nothing for more than two weeks." Now on the evening of his removal to the *Hygeia* and next morning three medical men with as good eyesight as it is possible to have examined him and could not see a trace of lymphangitis in the arm, even when local phalangeal trouble was already evident. The lymphangitis of the right arm was caused by the wound of June 27th. The question as to whether there will be "wound reaction" at the site of infection depends on the purity or impurity of the infecting material and the susceptibility and resisting power of the animal or person inoculated; and in the case of Chinese, who are notoriously susceptible to the disease and have little resisting power, it is little wonder that lymphangitis should be frequently absent seeing that they die usually from the first to the fourth day, before lymphangitis, when it is to occur, has had time to make itself apparent. Lymphangitis may occur late in the disease as a sequela, and when it does it often appears in what was probably the infected limb, of which Case 2 is an example.

CASE 2.—Dr. Ishigami, assistant to Mr. Kitasato. "Examination (June 29th) showed the absence of any open wound on the left hand (he had a left axillary bubo); but there was the mark of a small scar on one of the fingers where he said he had scratched himself some days before. ..... On July 26th lymphangitis of left arm, treated with lead and opium." I take this as an example of what probably often occurred in the epidemic—inoculation by a small wound, no wound reaction, no lymphangitis within the first few days, but developing later if the patient survived—even this last condition is not at all necessary. No mention of lymphangitis is made by Cerutti, who inoculated six Europeans to preserve them from the plague, five of them dying. Professor Aoyama and his assistants were always particularly careful of their hands whilst examining patients in the wards, using carbolic spray, &c.; but it struck me that in the post-mortem room, where there was far greater danger, they were careless in not using some antiseptic oil on their hands. Although they washed their hands afterwards in water and alcohol, yet there would be about two hours during the sectio cadaveris in which they could easily get infected.

CASE 3.—A policeman's wife was "admitted with sore between first and second toes, right foot; right femoral bubo and lymphangitis already suppurating." Here there was evidently a mixed infection of plague and streptococcus at once and suppuration was rapid.

These views on inoculation I have given somewhat fully, as this mode of infection has been ridiculed by some medical men in the Far East without having given much attention to the subject. The mere fact that many plague buboes in the groin and armpit suppurate whilst the internal enlarged glands in the same patient do not seems to bear out the fact that the streptococcus infection is practically stopped at the primary bubo, whilst a secondary plague infection of other glands goes on. The cervical glands rarely suppurated; perhaps in inoculation by the mouth the streptococci had not the same chance of entering the system. In one or two cases multiple abscesses were found, as one occasionally gets a pyæmia after septicæmia; but had these cases been infected by plague alone I do not think suppuration would have been found in disseminated foci. The better class Chinese do not suffer nearly so much from plague. Their houses are slightly cleaner than those of the lower classes, and they wear shoes with the trousers tied tightly round the stockings, thus cutting off a large amount of infecting ground.

Actual proof of infection from food will not be easily proved amongst Eastern races, and may arise from infection of the animals eaten or from infection of food or vegetables which have been exposed in plague houses. Infection by drinking water can only be possible where the most insanitary wells are allowed to exist. It will probably be found that, although the infection be carried to these by flies, mosquitoes, &c., it will not long survive in any well or pool where a free access of air is possible.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF EXOMPHALOS WITH OTHER MALFORMATIONS.

BY WALTER M. WOODHOUSE, M.R.C.S. ENG., L.R.C.P. LOND.,
SENIOR ASSISTANT MEDICAL OFFICER, KENSINGTON INFIRMARY.

A GIRL, aged twenty years, was admitted into Kensington Infirmary on Nov. 5th, 1896, suffering from syphilis. On examination it was found that she had mucous tubercle round the vaginal orifice and anus, besides a squamous eruption on her skin, which she stated had been there since her ninth year. The patient was thought to be in about the sixth month of pregnancy. Under anti-syphilitic treatment the mucous tubercles cleared up considerably and her general condition greatly improved. On Dec. 18th the patient had a sudden and somewhat copius hæmorrhage from the vagina. An examination was immediately made and the right foot of a fœtus was found to be presenting. After the other foot had been brought down some difficulty was experienced owing to two soft masses which were felt, one lying posteriorly to the abdomen and the other anteriorly to the head. The former of these was found to be the placenta, and a large swelling seemingly attached to the umbilical region; the latter, a tumour which ruptured prior to delivery, will be presently described. The mother made an uninterrupted recovery and is now to all appearances quite well. The fœtus showed no sign of life; at the same time, there was no evidence of maceration.

Necropsy.—The child, a female, was twelve inches in length, and, as far as the characteristics would permit one to judge, of about from six and a half to seven months' development. Both feet presented well-marked talipes varus. There was a general stunted appearance, the neck being absent, and the head, which was flat at the top with a curiously sloping posterior part, appeared to spring direct from the shoulders. The eyes were prominent and the upper lids seemed much swollen. Dissection proved the absence of the vault of the skull, except some part of the frontal bone, which was pressed back and closely approximated to the anterior part of the base. The roof of the orbit was absent, leaving the eyeball uncovered on its superior aspect, thus explaining the swollen appearance of the eyes. Various foramina for vessels and nerves could plainly be discerned after the skin flaps had been dissected back. What brain matter there was was contained in a tumour before mentioned over the cervical vertebræ and posterior part of the base of the skull. There was no bony matter behind the usual situation of the foramen magnum, which was absent. The neural arches were deficient over the entire spinal column, leaving the spinal canal unenclosed. Still more remarkable was the arrangement of the abdominal and thoracic viscera. The thorax appeared to be abnormally short. From the region of the umbilicus sprang a pedunculated mass the size of a large orange, the pedicle being an inch in diameter. From the opposite end arose the umbilical

Hosted by Google

cord, the length of which was one and a half inches. It may be inferred that the outer coat of the mass was amnion, since it was continuous with the amnion on the cord. On internal examination the mass was divided into two unequal parts by a flat structure composed of muscular tissue, no doubt diaphragm. The smaller, situated in the pedicle, contained the heart with its pericardium, the lower end of the œsophagus, and the lungs. This necessarily caused elongation of the trachea and bronchi. The large cavity—containing the stomach, the large and small intestines, liver, and spleen—was lined by a continuation of the peritoneum. The large intestine re-entered the true abdominal cavity and was continued as the rectum to the anus. The thoracic cavity was almost obliterated, containing only the thymus gland. The kidneys and pelvic organs were normal.

Kensington.

A CASE OF MALIGNANT DISEASE OF THE RECTUM; PERFORATION; DEATH; NECROPSY.

BY ALONZO G. RIDER, M.B. LOND.,
ASSISTANT SURGEON TO THE ROYAL ALBERT HOSPITAL, DEVONPORT.

ON Sunday morning, May 24th, 1896, I was asked to see a widow woman, aged sixty years, as she was in pain in her abdomen. Before I reached the house, however, another medical man had been called in, as the pain had become much worse. I did not see the patient, but learned from the patient's daughter that she was much easier after a hypodermic injection of morphia. Next day I was asked to see the patient, and the history obtained was as follows. The patient was seemingly in perfect health till Sunday morning about eight o'clock, when she was taken with pain in her abdomen, which increased rapidly in severity. (There was no error in diet to account for this attack.) The pain seemed to radiate from the umbilicus, where it was most severe, all over the abdomen. Vomiting set in soon after the attack; it was persistent, at first bile-stained and afterwards brownish and offensive. It was not feculent. The history obtained gave two or three months alternating constipation and diarrhœa. Bright blood was often passed with the motions, which were frequently flattened. There had been no bladder or uterine troubles. Occasionally the patient felt some dull, aching pain over the sacrum, but with this exception she said "she had never felt better in her life till this attack commenced." There had been very little loss of flesh. The bowels were easily moved by mild aperients. There was nothing definite with regard to the family history. When seen the patient was lying on her back with both legs drawn up. The features were pinched; the extremities cold and clammy. The pulse was 90, weak, and of low tension. The respirations were 24, not markedly costal. The temperature was 97 4° F. The tongue was dry and covered with thick whitish fur. The abdomen was distended. There was no evidence of fluid in the peritoneal cavity. There was tenderness all over the abdomen especially around the umbilicus. In the right iliac region a swelling the size of one's fist could be felt; it pitted on deep pressure. There was no œdema of the legs. Nothing could be detected per vaginam or per rectum. Malignant disease of the large intestine, probably the rectum, was diagnosed with acute intestinal obstruction supervening on the chronic condition, and the patient was as soon as possible removed to the Royal Albert Hospital with a view to having colotomy performed. She, however, rapidly became worse and died before any operation could be performed about six hours after admission.

Necropsy.—There was no free gas in the peritoneal cavity; in Douglas's pouch there was about half an ounce of brown-coloured fluid with a fæcal odour. Some of the lower coils of the small intestine were covered in places with recent lymph. In the upper third of the rectum there was a growth surrounding the bowel for a distance of one and a half inches. It almost entirely occluded the lumen of the gut. On the left side of the bowel there was a recent ulceration, passing through all its coats large enough to admit a No. 3 catheter. No secondary deposits were found. The appearance of the growth was carcinomatous, but no microscopic examination was made.

Devonport.

CASE OF PAPILLOMATA OF THE LARYNX IN A CHILD; RECOVERY AFTER TRACHEOTOMY.

BY G. HUNTER MACKENZIE, M.D. EDIN.,
SURGEON FOR DISEASES OF THE THROAT AND NOSE TO THE EYE, EAR, AND THROAT INFIRMARY, EDINBURGH.

A BOY, aged two and a half years, was sent to me at the Eye, Ear, and Throat Infirmary on Sept. 4th, 1895, by Dr. McCreadie of Leith. His voice had been husky from birth, and for a year previous to admission the vocal symptoms had grown appreciably worse. Latterly the respiration had become noisy and somewhat impeded, especially when he had "cold," to attacks of which he was now very subject. He had been singularly free from the usual troubles of infancy and childhood. On admission the boy was in poor general condition, the respiratory act was noisily performed, and inspiratory dyspnœa was distinctly, but not markedly, present. He spoke in a whisper. An attempt to use the laryngoscope alarmed him and induced an aggravation of the respiratory difficulty with spasm. He was accordingly chloroformed and again examined, without, however, very definite results. On Oct. 7th he had become so much worse that tracheotomy had to be performed for the relief of the breathing. Great improvement followed and he was dismissed in about a week.

The subsequent history of the patient may be briefly summarised. The tracheotomy tube was worn for seven months. During this period pieces of warty-looking growths were detached from time to time and were coughed up, usually at such times as the tube was removed for cleansing purposes. Ten such pieces, the largest being of about one-half the size of a grain of rice, were detached and recovered from the expectoration and secretion of the trachea and tracheal wound. These were found to be papillomatous in structure. In June, 1896, being seven months from the date of operation and two months from the time of expectoration of the last piece of growth, it was determined to remove the tube and close the tracheal opening, and although for a few weeks the breathing was at times greatly impeded, especially during sleep, it gradually improved, and re-insertion of the tube was not necessary. The boy (in January, 1897) breathed quite freely, and about a month previously his normal voice had been heard for the first time.

Remarks.—This case is recorded as an example of the success which attends the treatment of papillomata of the larynx in children by simple tracheotomy. There is abundant evidence to show that forcible removal of these growths by intra-laryngeal or extra-laryngeal operations is very apt to be followed by rapid and frequent recurrence. Not only so, but in the case of the last mentioned (thyrotomy) being adopted an additional and serious drawback is probable in the form of permanent injury to the voice. The disease, it will be noted, seems to have been congenital, which is occasionally the case, although more frequently it appears as a sequel of one of the exanthemata, usually measles.

Edinburgh.

AN UNUSUAL RESULT OF ABORTION.

BY C. E. PURSLOW, M.D., M.R.C.P. LOND.,
HONORARY OBSTETRIC OFFICER, QUEEN'S HOSPITAL, BIRMINGHAM.

THE patient from whom the specimen which I am about to describe was obtained was the mother of three children. During her last pregnancy she suffered in the early months from retroflexion of the gravid uterus. This was rectified and a pessary worn for two months, and the condition gave rise to no further trouble. On this occasion she had not menstruated for eighteen weeks and had all the signs of normal pregnancy. She was then seized with somewhat severe labour pains, and when I saw her the fœtus contained in its amniotic sac had been expelled and was lying in the bed. The placenta could be felt presenting at the os, and as pains were going on regularly it was not interfered with and the placenta and membranes were expelled in about two hours' time. A douche was then given and the patient made a normal recovery. No discharge of any kind had preceded the expulsion of the amniotic sac. On examining the specimen it was seen that the fœtus, about six inches long, was enclosed in the intact amniotic sac with

Hosted by Google

the liquor amnii. There was no trace of chorionic or placental tissue on the outer surface of the amnion, and the fœtus could be plainly seen through the walls of the sac. The umbilical cord had given way at its placental attachment and its torn end was very distinctly seen as a depression on the surface of the sac, the whole length of the cord lying in the sac with the fœtus. The specimen is now in the museum of Mason College. The expulsion of the entire sac of the ovum is fairly often met with at all stages of pregnancy, but such a result as the one I have described appears to me to be extremely unlikely to occur, and it is with the object of discovering whether any of the readers of THE LANCET have ever met with such a specimen that I have written this note, as I can find no reference to any similar specimen having been described.

VICTORIA HOSPITAL FOR CHILDREN.

A CASE OF PURULENT CEREBRO-SPINAL MENINGITIS; DIAGNOSIS BY MEANS OF LUMBAR PUNCTURE; NECROPSY.

(Under the care of Dr. DAWTREY DREWITT.)

PUNCTURE of the spinal canal and evacuation of the cerebro-spinal membranes in cases of tuberculous meningitis have been practised with varying success. This case illustrates its advantages as an aid to diagnosis in other diseases of the spinal cord. The puncture itself is unlikely to cause any injury if performed with ordinary care, and the position of the cauda equina in young children—lying in two bundles on either side of the canal—makes the nerve elements at the point usually selected practically safe from injury. Mr. Power gives a description of the operation in his book on Surgical Diseases of Children. For the notes of the case we are indebted to Dr. Louis B. Hayne, house physician.

A girl, aged ten years, was admitted into the wards of the hospital on the night of Dec. 15th, 1896, under the care of Dr. Dawtrey Drewitt, with the history that from infancy she had suffered from intermittent attacks of otorrhœa, mainly on the right side; she had never been really well since she had diphtheria three years previously. Recently she had been studying hard at school. On Dec. 5th she had right-sided earache with a little discharge, and on the 8th the present illness commenced, with headache and vomiting. She was kept in bed for a week, the main symptoms being drowsiness and headache. There was no action of the bowels after the 9th. On the 16th, the morning after her admission into the hospital, symptoms of cerebral irritation were present. The head was markedly retracted and the child constantly cried out in a semi-delirious manner, complaining of headache mostly over the right frontal and temporal regions. The temperature was 102·8° F., and the pulse was rapid but regular. The tongue was dry and brown. There was vertical nystagmus on fixation and also optic neuritis; and there were a few flakes of pus on the right membrana tympani. A rigor, the temperature rising to 104·8°, occurred during examination. The knee-jerks were absent; there were no localising symptoms. By the advice of Mr. D'Arcy Power the sub-arachnoidean space was punctured at the level of the third lumbar spine by a fine trocar and cannula, a test tube full of foul-smelling pus being withdrawn. The child was considerably relieved and slept quietly for three or four hours; symptoms of irritation, however, returned, which terminated with death twelve hours later.

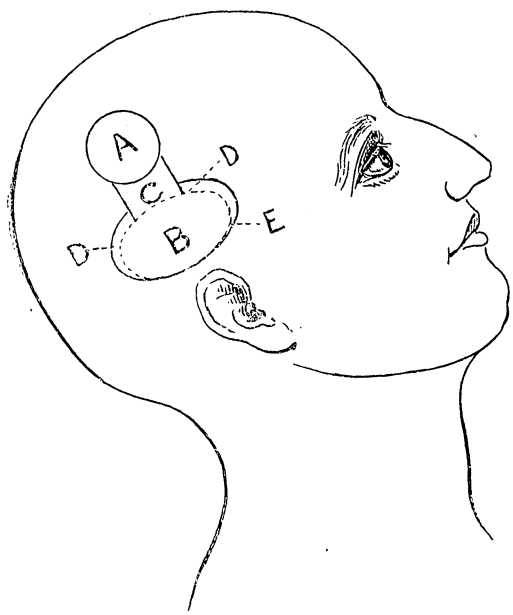
Necropsy.—At the post-mortem examination purulent lymph and pus, somewhat offensive in character, were found covering the base of the brain and of the left lobe of the cerebellum, with considerable matting together of the parts. The base of the right lobe of the cerebellum was normal; the brain substance was also normal. The spinal membranes and cord were covered with pus of a similar nature. No evidence of middle-ear disease was discovered.

Remarks by Dr. L. B. HAYNE.—Lumbar puncture, carried out with the ordinary aseptic precautions, serves as a useful addition to our diagnostic aids in cases where there are no signs to enable us to distinguish between cerebral irritation as the result of a general and that the result of a local condition. In this case the history of previous attacks of right otorrhœa might reasonably have led one to suspect the presence of an acute cerebral abscess, and undertake the operation of trephining accordingly. The futility with which such an operation in this case would have been undertaken was happily avoided by the formation of the diagnosis afforded by the preliminary lumbar puncture.

STANLEY HOSPITAL, LIVERPOOL.

A CASE OF TRAUMATIC EPILEPSY; TREPHINING; IMPROVEMENT.

(Under the care of Mr. G. P. NEWBOLT.)



OPERATION for the relief of traumatic epilepsy is placed on a firm footing and many cases of its successful accomplishment are on record, yet the account of a case such as the following, in which the lesion was an extensive one, will always be of interest to those engaged in surgical practice. Although the patient does not appear to have received the full benefit hoped for from the operation, still there is no doubt of the improvement which has ensued. More than one case is known in which the removal of a spicule of bone which projected from the under surface of the skull was sufficient to relieve the patient of his fits, and a case is on record in which such a spicule was found near the trephine opening after death. The operator had failed to discover a cause for the attacks at the time of the operation. In a collection of 82 cases 72 had a distinct history of some lesion to the head. In 46 out of these 72 there was a fracture, which was compound and depressed in 26 cases. The exact seat of the lesion is not given accurately in a large majority of the cases. In 45 it was over one or the other parietal, in 14 over the frontal, and in 3 over the occipital area.[1]

A sailor, aged forty-five years, was admitted to the Stanley Hospital on April 3rd, 1894, suffering from epileptic fits apparently due to an old injury of the head. The following notes, giving the early history of the case, were obtained from the surgeon under whose care the patient came directly after sustaining the injury at Boston, U.S. On Dec. 13th, 1888, whilst weighing anchor a chain parted and the end of it struck the patient on the right side of the head, inflicting a compound comminuted fracture of the skull, from which brain substance and blood exuded. On admission to the Boston Hospital there was a wound the size of a silver dollar half an inch above and posterior to the external ear. Under ether one large detached fragment and several other depressed fragments of various sizes were removed, a small amount of brain substance was washed out, and the wound was closed as far as possible, but there was not sufficient scalp to cover it completely. The patient was delirious and had to be restrained for four days, but at the end of that time he was fairly rational. On Jan. 27th, 1889, he was up and dressed for the first time, and said that on the previous day all at once his memory and senses came to him, and he knew who he was and where he was. On the 30th he was quite rational, and remembered everything except what had occurred during his stay at the hospital, but he recollected nothing about the accident. The granulating surface of the wound lay about three-quarters of an inch below the surface of the scalp and pulsated visibly. On Feb. 10th his eyes were examined, with the following report: "V.O.U. $\frac{20}{20}$; the fundus is normal; there is complete hemianopsia; the left side of the field is gone in both eyes, the division line being practically vertical and running across the fixation point. The eyes were not absolutely steady during examination, but enough so to make the general result unquestionable." On the 16th he was examined by a neurologist with the following result: "Smell, sensation, and motion are normal. He reads fluently. The grasp is strong, the dynamometer recording—right hand 100, and left hand over 95. The triceps, radial, ulnar, and epigastric reflexes are absent, the abdominal

[1] Jacobson: The Operations of Surgery, second edition, p. 186.

Hosted by Google

cremasteric and plantar reflexes being present. The knee-jerk is slightly greater on the left side; he stands with the eyes shut. There is hemianopsia." On March 30th he was discharged well. For two years after the accident the patient was perfectly well, and then whilst working he had a fit and dropped as if shot. Since that date (March, 1891) he had had fits at intervals varying from two weeks up to two and a half months. Before the fit came on he had a sensation of numbness and then pain starting about three inches above the left wrist on the inside. The pain shot down the inside of the wrist and around the back of the hand and also passed up to the shoulder. He then became unconscious for about five minutes and was a quarter of an hour in coming to himself. Lately he had had pain in the left wrist and ankle, also at the seat of fracture, and at the corresponding point on the other side of the skull. On account of these fits he could get no employment whatever and consequently was most anxious that some operation should be done. On admission to the Stanley Hospital the patient was a strong, healthy looking man. There was an oval depression in the bony wall of the skull on the right side above, and posterior to, the external ear. It was three-quarters of an inch deep and at the bottom of it the brain pulsated. When he lay down this depression filled up whichever way he turned his head. There was a distinct impulse on coughing. The bony margins of this depression were rounded, but there were fissures in it anteriorly, posteriorly, and below. The antero-posterior diameter was one and a half inches. From above downwards it was two inches, and the lower edge was one and a half inches above the centre of the external auditory meatus. There was no paralysis, but he was slightly deaf on the left side and hemianopsia was present. On April 6th, 1894, the head having been completely shaved and rendered aseptic, chloroform was given and a big semicircular flap was turned down from the right side of the skull, its base being level with the top of the depression. A circle one and a half

A, Trephine centre. B, Old wound. C, Bone removed between trephine centre and old depression. D, Margins pared. E, Spot where spicule was found.

inches in diameter was then raised from over the wrist centre, but the parts beneath were apparently healthy; and so, having reflected the flap lower down, Mr. Newbolt removed the portion of bone (C) between the trephine circle and the edge of the depression. The adhesions betweeen the cicatricial tissues covering the old wound and the edges of the bone (DD) were next separated and the bone pared all round except at the base. Whilst doing this a spicule of bone was discovered in the anterior corner of the wound (E) and underneath it a small cyst. The spicule was removed and the cyst opened. All hæmorrhage having been stopped, the pieces of bone removed were cut up and re-implanted, the wound was completely closed, and the patient returned to bed. On the 16th he was allowed to be up. By the 18th the wound had healed by first intention and the replaced bone had formed a dense cicatrix over the part on which it was placed. On May 4th he left the hospital. His last fit before the operation occurred on March 18th, 1894. He kept perfectly well until Nov. 2nd, when he had a slight fit, not so severe as the others, and he was able to walk home soon after it. This was seven months after the operation. At the end of May, 1895, whilst at Santos, he had a second fit, another interval of seven months having elapsed, and at the end of September, 1895, a third took place, the interval being four months. When last seen, on March 12th, 1896, the patient had remained well and had not suffered from another fit. He still had hemianopsia and slight deafness. The replaced bone had become quite firm and the old depression still existed.

Remarks by Mr. NEWBOLT.—I report this case as I think it is interesting both in itself and from the early history of the accident. I am inclined to think that adhesions probably have had a good deal to do with the onset of the fits, though the spicule may have acted as an irritant. It will be interesting to follow the history of this patient and to see whether the fits increase in frequency or not. He was shown at the Liverpool Medical Institution.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Urine in Typhoid Fever.—Nervous Symptoms in Typhoid Fever.

A MEETING of this society was held on Feb. 8th, the President, Dr. HOWSHIP DICKINSON, being in the chair.

Dr. P. HORTON-SMITH read a paper on the Occurrence of Typhoid Bacilli in the Urine of Patients suffering from Typhoid Fever. He referred to the observations of previous writers who had found the bacilli present in a varying number of the cases examined, and in some as early as the first week. He thought, however, that these results ought to be accepted with some caution, as sufficiently stringent precautions did not appear to have been taken to distinguish the organism from the bacterium coli commune. In all his cases he had made careful negative tests and excluded this fallacy. The urine was passed with careful precautions into a sterilised flask. Plate cultures were made (*a*) by smearing drops of urine on the gelatin surface; and (*b*) by filtering the urine through a sterilised Chamberland's bougie and making cultures from the deposit. Their identity as typhoid bacilli was confirmed by their appearance, and especially that of their cilia under the microscope; by their not evolving gas when cultivated in gelatin; by their not coagulating milk, even after a month; and by their reaction with typhoid serum. He had observed eight cases, involving sixty-one examinations, in which he had established the presence of typhoid bacilli in the urine. He had never been able to find it in the early stages of the disease, and therefore the diagnostic value of a positive observation was small. The investigation showed that it was important to disinfect the urine as well as the fæces of patients suffering from typhoid fever.—The PRESIDENT drew attention to the important practical conclusion to which this scientific investigation had led.—Mr. H. E. DURHAM asked whether in any of these cases of undoubted typhoid fever Widal's serum reaction had been tried during life. He did not find the test so reliable as he had been led to expect, and it was specially important to have information as to its presence or absence in cases which were shown bacteriologically to be true cases of typhoid fever.

Dr. JOHN ABERCROMBIE read a paper on Some Affections of the Nervous System met with in Association with an Attack of Typhoid Fever. He thought that the imbecility occasionally met with was mainly due to insufficient feeding. He described the case of a boy who was very delirious during the first two weeks and then passed to a condition of mental dulness, but resented any attempt to feed him, nasal feeding being necessary, except for a short interval, for two months, during which time he remained in the same imbecile condition. He quite recovered his mental equilibrium a

Hosted by Google

month later. Some peripheral paralysis came on during his convalescence, but ultimately recovery was complete. Although rigors usually suggested peritonitis or perforation they might have no grave significance, and in several cases quoted appeared to be simply dependent on constipation. He (the speaker) described one case and quoted others observed by Osler in which rigors were associated with the occurrence of venous thrombosis. He had met with two cases of convulsions in the course of typhoid fever. In the first case the fever came on a few weeks after a perfectly normal labour; the initial diarrhœa had given way to treatment and the bowels were acting daily. During the third week the patient had four convulsions, for which there was no evident cause. It was believed that the convulsions were reflex, and although the bowels were acting daily it was decided to give a glycerine enema. A large, pultaceous, very offensive stool was evacuated; the patient's temperature came down to 101° F. that night, and she had no more convulsions. The second case occurred in a man, thirty-five years of age, who had a convulsion on the forty-first day which was apparently due to the occurrence of venous thrombosis.—Dr. HERRINGHAM said he had seen cases of imbecility occurring in patients who were in hospital and taking a full amount of nourishment. Insufficient food could only be regarded as one of the factors. Rigors might be due to quite trivial causes, and some people seemed specially liable to them. He thought there was an analogy between the temperature curve and the epileptic paroxysm, the early sustained pyrexia corresponding to the tonic stage, the fluctuating temperature during defervescence to the clonic stage, and the rigors to the sudden irregular jerks which are so often seen at the close of a convulsion.—Dr. DE HAVILLAND HALL had seen a case in which rigors occurred with symptoms of heart failure; no explanation was found for their occurrence, and they did not delay the recovery.—Dr. JOHN HARLEY insisted on the close relation between typhoid and intermittent fevers. He thought there was an inherent tendency to rigors, especially in severe cases. Typhoid fever had a way of bringing out any weak spot in the nervous system, and he quoted cases in which transient paralytic symptoms showed themselves during the course of the fever.—Dr. NORMAN MOORE mentioned two cases in which rigors were followed by the passage of pus in the urine. It was difficult in such cases to tell if the formation of pus were due to the attack of fever or were antecedent to it. He thought that the mental weakness was in great part attributable to the long duration of the fever.—Dr. RUSSELL WELLS referred to cases of typhoid fever in which symptoms of cerebro-spinal meningitis occurred. No lesion was found in those cases which were examined after death, and the symptoms appeared to be due to the circulation of some chemical poison.—Sir DYCE DUCKWORTH thought that the long duration of the disease was one of the most important factors in producing mental weakness. Mania and melancholia were frequently met with after typhoid fever, and both they and the more severe forms of delirium are usually associated with a neurotic family proclivity. He hardly agreed as to the existence of any close relation between typhoid and intermittent fevers.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Feb. 8th, the President, Mr. REGINALD HARRISON, being in the chair.

Dr. MORGAN DOCKRELL showed a case of Withering Sarcoma of the Scalp of fifteen years' duration. The case was shown by the late Mr. Morrant Baker nine years ago and fully reported in the St. Bartholomew's Hospital Reports; it had remained quiescent until a few months ago, when it became more active and acquired a condition of mycosis fungoides. The question arose whether such a case was suitable for the injection of Coley's fluid.—Mr. G. R. TURNER asked if the discharge had been examined for the ray fungus. He thought that such a growth as this patient exhibited appeared too extensive for the use of Coley's fluid.—Dr. DOCKRELL, in reply, said that he had found that when a condition of mycosis fungoides was present these cases did best with Coley's fluid. He thought that as the growth was increasing it was worth while to try the injection of the fluid.

Mr. NOBLE SMITH showed a woman who ten years previously had sustained an Injury to the Second Finger of the Right Hand. The finger was amputated. He also showed a case of Diffuse Lipoma and Congenital Deformity of the Phalanges of the Index Finger in a woman who, at the age of fifteen months, fell down some steps and injured the thumb and index finger of the right hand. A full report of these two cases is published at p. 431 of our present issue.

Mr. J. H. MORGAN showed a man, aged twenty-six years, with Bi-temporal Hemianopsia after Compound Fracture of the Anterior Fossa of the Skull. He had fallen from a height and fractured the patella; he vomited a considerable quantity of blood, had ecchymosis of both eyelids, blood in the nostrils, and conjunctival hæmorrhage on the right side. He developed a condition of cerebral irritation. More than a month later a swelling was noticed in the upper part of the right orbit with a bony margin, and emphysema was present in this region, which lasted several days. It was found that he had loss of vision in both temporal fields. The discs were pale and probably in a condition of early atrophy. Mr. Morgan thought the fracture involved the anterior fossa and the orbital plate on the right side.

Mr. F. C. WALLIS showed a boy, aged sixteen years, who fell on his shoulder through a distance of thirty feet and caused a longitudinal fracture of the great tuberosity of the humerus just below the insertion of the muscles. This portion of bone sprang away from the shaft, but was not separated from it, and tore through the fibres of the deltoid. An incision was made and it was found that in the abducted position of the arm the splintered bone came nearly into position; subsequently, however, it was necessary to remove the projecting portion of bone. The boy made a good recovery and has good movement in the arm.

Mr. G. R. TURNER showed a case of Excision of the Head of the Radius for Old Unreduced Dislocation in a Soldier who was thrown whilst driving a cart. He sustained a fracture of the ulna about the middle and dislocation forward of the radius. A skiagram showed that the head of the radius was dislocated forwards. The head of the radius was excised, care being taken not to interfere with the tuberosity of the biceps. The man made a good recovery and was able to pronate and supinate well, power of flexion being limited.—Mr. F. C. WALLIS asked if any treatment short of operation had been tried.—Mr. WATERHOUSE said that he had, in a child eight years of age, been able, after making an incision, to force the head of the bone back into position with a periosteal elevator.—Mr. TURNER, in reply, said that he had tried manipulation under chloroform. He did not think that it was likely in such a case as this that reduction could be performed, and that these cases often seemed to do better when the head of the bone was excised than they did even if one succeeded in reducing the dislocation.

Dr. R. MAGUIRE showed a case of Malignant Disease of the Lung in a man, aged fifty-two years, who complained of shortness of breath and cough, the first complaint being, however, difficulty in swallowing. He had dulness over the upper part of the left lung with loud bronchial breathing. He thought that infiltration of the lung by new growth had taken place along the bronchi. The œsophagus allowed a bougie to pass easily.

Dr. R. MAGUIRE showed a second case of a man with Congenital Heart Disease, aged twenty-two years. He had had rheumatic fever three times, but when only seven months old he had been seen at Brompton Hospital by Dr. Pollock, and was then said to have had heart disease.

Mr. SWINFORD EDWARDS showed a Skiagram of a Knee-joint after Suture of the Patella from a man, aged thirty years, in whom he had wired the patella on the ninth day after the accident.

Dr. G. STOKER showed two cases of Ulcers treated with Oxygen Gas, the one ulcers on the leg, the other lupus of the nose. In the latter case scraping the surface had been combined with treatment by oxygen; both conditions had considerably improved since being under treatment.

OBSTETRICAL SOCIETY OF LONDON.

Exhibition of Specimens.—Annual General Meeting.—President's Address.—Election of Officers.

A MEETING of this society was held on Feb. 3rd, the President, Dr. F. H. CHAMPNEYS, being in the chair.

Mr. DORAN showed the following specimens:—1. Fibroma

Hosted by Google

of Ovary; Impaction; Ascites; Removal. A year before removal this tumour was impacted in the pelvis; the uterine cavity measured three and a half inches. It was reduced with ease. In the autumn ascites set in and the uterus measured four inches; the tumour, eight inches broad, lay in the abdomen across the pelvic brim and quite moveable. Mr. Doran removed it on Jan. 12th. The pedicle was five inches broad and very short, otherwise no difficulty was encountered and the patient did well. She was forty-nine years of age. 2. Lipoma of the Lumbar Region, four pounds in weight and of twenty years' growth. The patient was aged fifty-five years and had borne ten children. She was very corpulent. In 1876 it measured three inches and remained about that size till 1891, when it began to grow very rapidly. It was removed in 1894 without any difficulty; it then measured nineteen inches in its long diameter, bulging conspicuously from the loin forward and outwards. 3. Fibroma of the Abdominal Wall increased during Pregnancy. The patient was aged thirty-two years and had borne five children. The tumour was first seen in December, 1895, and the patient became pregnant shortly afterwards. It increased over two inches in its long diameter during pregnancy and was removed five weeks after delivery. It lay in the substance of the left internal oblique muscle and probably originated in the conjoined tendon. Neither the external oblique muscle nor the peritoneum was involved or adherent to the tumour. Mr. Doran called the attention of the society to the great predominance of parietal tumours of this kind in women.

Dr. JOHN PHILLIPS showed a Fœtal Monstrosity (Hemicrania). The mother, a young primipara, was delivered at the eighth month of pregnancy; the labour was complicated by marginal placenta prævia. The fœtus presented by its face and labour terminated with the chin to the anus as in first vertex delivery. The placenta was of enormous size and irregular shape. The fœtus was stillborn. The external appearance of the monstrosity is exactly depicted by Ahlfeld, the characteristic frog-like attitude being well seen. The tumour over the site of the occipital and upper spinal regions had been removed in the specimen and was found to consist of a broken-down brain substance with various nerves passing from it. The whole of the posterior portion of the cranial vault and the posterior vertical laminæ were entirely absent. The lower jaw articulated in a fossa in normal relation to the zygoma. The generative, digestive, cardiac, and pulmonary systems were normal. The fœtus was a female. The left foot had an equino-varus and the right a calcaneo-valgus.

Mr. TARGETT showed a specimen of Ruptured Gestation in an ill-developed right uterine cornu. The gestation sac was connected with the cervix of the well-formed left cornu by a small, rounded cord which seemed to be traversed by a minute canal. This cord was three inches long and represented the lower end of the Valerian duct. The evidence that the gestation sac was uterine and not tubal rested upon the facts that the right round ligament took origin from it and that the sac possessed a normal right broad ligament with a Fallopian tube and ovarian ligament of the usual length. The left cornu was lined with decidua and its cervix plugged with mucus. A rupture of the sac was caused by vomiting in consequence of the administration of an aperient draught and was speedily fatal. The patient was in the fifth month of pregnancy.—After remarks from Dr. MACNAUGHTON-JONES, Dr. GRIFFITH said he had carefully examined two similar specimens with the object of endeavouring to identify and trace the Mullerian duct or any channel of communication between the developed and the undeveloped horn containing the gestation sac. The method he adopted was by microscopical section through the whole thickness of the septum uniting them. He had failed to find any trace of such a canal in either specimens, and he placed no reliance on a bristle for this purpose, which would naturally find some passage along the bundles of muscle fibres or some vessel or nerve.—Remarks were also made by Dr. MACLEAN.

Dr. CULLINGWORTH exhibited a specimen removed by operation a few hours previously consisting of the Fallopian Tubes and Ovaries. The right Fallopian tube was enlarged, tortuous, and completely occluded by adhesion of its fimbriated extremity to the surface of the ovary. Its diameter was one inch and its length four and a half inches. Its lumen was dilated and contained about half a fluid ounce of greenish-yellow pus without odour. The mucous lining was covered with granulation tissue without any trace of ulceration. The right ovary was enlarged, and on section was seen to contain a large number of small abscesses with walls of thick, opaque, whitish tissue, giving them the appearance of degenerate corpora lutea. Dr. Cullingworth said that he exhibited the specimen chiefly on account of the interest attaching to the condition of the ovary. It was unusual to find a large number of small abscesses in the ovary except in tuberculous disease. In this case he believed the inflammation to be of gonorrhœal origin, the purulent vaginal discharge during the first inflammatory attack having probably been due, not to the bursting of an abscess, as was then supposed, but to acute gonorrhœa. The result of the operation showed that nothing short of complete removal of the diseased parts would have sufficed to give the patient relief.—Remarks were made by Dr. STEVENS, Dr. MCCANN, and Mr. GANDY.

The annual general meeting of the society was then held. The reports of the honorary treasurer (Dr. Potter), the honorary librarian (Dr. Griffith), and the Chairman of the Board for the Examination of Midwives (Dr. Cullingworth), respectively, were read and adopted, and a vote of thanks passed to each gentleman.

The laws as revised by the Council were confirmed.

The PRESIDENT then delivered his Valedictory Address; and it was moved by Dr. Potter and seconded by Dr. Hurry, "That a vote of thanks be accorded to the President for his address, and that he be requested to allow it to be printed in the next volume of the Transactions." This was carried unanimously.

A vote of thanks to the retiring Vice-President and Members of Council, proposed by Dr. Playfair and seconded by Dr. Sinclair, was passed.

The names of the officers recommended by the Council and elected were as follows:—President: Dr. Charles James Cullingworth. Vice-Presidents: Dr. William Duncan, Dr. John H. Galton, Dr. Thomas Cargill Nesham (Newcastle-on-Tyne), and Dr. Jamieson Boyd Hurry (Reading). Treasurer: Dr. John Baptiste Potter. Chairman of the Board for the Examination of Midwives: Dr. Percy Boulton. Honorary Secretaries: Dr. William Radford Dakin and Dr. John Phillips. Honorary Librarian: Dr. Walter S. A. Griffith. Other Members of Council: Dr. Thomas Rutherford Adams (Croydon), Dr. John Walters (Reigate), Mr. Joseph Thompson (Nottingham), Mr. Albert Kisch, Dr. Arthur Nicholson (Brighton), Mr. Richard Pinhorn (Dover), Dr. Thomas Watts Eden, Dr. Amand Routh, Dr. Frederick John McCann, Mr. William Gandy, Mr. George Henry Pedler, Dr. Montagu Handfield-Jones, Dr. William Rivers Pollock, Dr. Alfredo Antunes Kanthack, Dr. Angus Fraser (Aberdeen), Dr. Harold A. Des Vœux, Dr. Charles Hubert Roberts, and Dr. Walter W. H. Tate.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.

Double Harelip and Cleft Palate.—Deafness following Bilateral Dislocation of the Jaw occurring during Extraction.—Cement and Amalgam as a Filling.

AN ordinary meeting of this society was held on Feb. 1st, Mr. R. H. WOODHOUSE, President, being in the chair.

Mr. MESSENGER exhibited models and related the history of a case of Double Harelip and Cleft Palate. The operations for remedying the harelip and cleft palate had proved successful, but the maxilla, owing to the operations, was V-shaped and the mandible very prominent, the lower lip having a strong tendency to drop.

Mr. BOWDEN recounted an interesting case of Deafness following Bilateral Dislocation of the Jaw occurring during Extraction. The patient, a female, aged thirty-seven years, had the three left mandibular molars removed, nitrous oxide being administered as an anæsthetic. On the patient's regaining consciousness it was discovered that there was a bilateral dislocation of the jaw, which was easily reduced under the influence of a further dose of the anæsthetic. Two weeks subsequently the patient was found to be absolutely deaf in the left ear. The patient was then seen by Mr. Cumberbatch, who stated that his first impression was that the deafness was nervous in character from the shock of knowing that the jaw had been dislocated, but the presence of pain did not support this view, as primary affections of the labyrinth were not painful. The suggestion he made was that the violent wrench on the jaw by pulling on the

Hosted by Google

cartilaginous meatus, and through that the membrane, had set up inflammation of the tympanum which spread to the labyrinth. About three weeks after the operation the condition of deafness began to improve.

Mr. H. BALDWIN read a communication on Cement and Amalgam as a Filling. After detailing the method he usually employed he remarked that as a filling the combination of cement and amalgam had distinct advantages over amalgam, as in addition to being entirely free from the many objections to which the latter was open it possessed the following points of merit as compared with either amalgam or gold: (1) it required a much smaller sacrifice of healthy tooth substance and (2) therefore left a stronger tooth; (3) it necessitated less pain in excavating; (4) it interposed a non-conducting layer between the sensitive denture and the metal; and (5) it was thoroughly water-tight. In addition, the rapidity with which the combination could be employed, and the absence of a tendency to stain the tooth, must also be regarded as distinct advantages. Mr. Baldwin stated that he had used the method with increasing frequency for over thirteen years, and stated that the results he had obtained had been most gratifying.—Mr. ROBBINS referred to the fact that amalgam as a filling was receiving proper scientific attention from such investigators as Mr. Tomes in this country and Dr. Black in America. He spoke in favour of the continuation of cement with amalgam.—Mr. A. E. BAKER, Mr. CUNNINGHAM, Mr. RUSHTON, Mr. HUMBY, Mr. HERN, Mr. MATHESON, and Mr. LLOYD-WILLIAMS also took part in the discussion.

HARVEIAN SOCIETY OF LONDON.

Smoking at Non-clinical Meetings.—Polyneuritis in Children.—Primary Sore on Lip.—Rodent Ulcer.—The Oxygen Treatment of Ulcers.

A MEETING of this society was held on Feb. 4th, Dr. R. H. MILSOM, President, being in the chair.

The PRESIDENT, in opening the discussion upon the subject of smoking being allowed at ordinary meetings, said that whilst considering the views of the smokers it was also necessary to look at the question from a much broader point of view. The society was one of the oldest medical societies in London, and the members ought to be very careful not to introduce any innovation which would be detrimental to it or lower the prestige with which it had been handed down to them by their predecessors.—Dr. NORMAN KERR was opposed to the introduction of smoking at ordinary meetings. Though unable now to smoke he had been a smoker for a long series of years and had derived much enjoyment therefrom; but he had always looked upon it as a matter of fairness and honour never to enjoy the "divine weed" in the presence of those who neither approved of nor relished the use of tobacco.—Dr. THOMAS MORTON, Mr. JULER, and others spoke against the proposition, which was negatived by a unanimous vote.

Dr. LEONARD GUTHRIE showed two boys, each aged five and a half years, who had suffered from Polyneuritis. Case 1 was admitted to the Children's Hospital, Paddington Green, on Oct. 5th, 1896. Twelve days previously he had suddenly lost power in his hands and arms; in a few hours his legs became similarly affected. Two days later he was unable to walk. He complained of headache and pains in the limbs when handled. He had been slightly delirious at night and the bowels had been relaxed. His previous health had always been good. There was no history of diphtheria or any form of sore-throat. On admission he was healthy-looking and well nourished. The eyes were normal except for slight nystagmus in looking to the left. The palate was unaffected and the voice was natural. He was unable to sit up or stand without support and could not walk at all. The movements of the upper extremities were all weak, and the hand-grasp so much so that he let objects slip through his fingers and could not feed himself. The legs below the knees were bluish, cold, and tender on pressure. He cried with pain behind the knees when made to stand. There was foot-drop on both sides and power of dorsiflexion of the feet was much impaired. The extensors of the legs and feet did not react to galvanism or faradism. The knee-jerks and plantar reflexes were absent. Otherwise he seemed well. The treatment was massage and galvanism, together with daily injections of liquor strychniæ, beginning with one minim, and increased by half a minim every other day until the dose reached ten minims. By Nov. 4th he was able to sit up in bed and feed himself, but could not stand alone. The extensor muscles of the legs had wasted and also the thenar and hypothenar eminences in both hands to a slight extent. Henceforth he gradually improved, becoming able first to stand and then to walk alone. At the present time the only symptoms which remained were slight dropping of the feet in walking and loss of knee-jerks. Case 2 was admitted to hospital on July 16th, 1896, with symptoms resembling those of cerebellar disease. Nine weeks previously he had begun to tremble and shake, his gait became unsteady, and he often fell down. Five weeks later his face was drawn to the right side and he complained of pain in the left side of the face and head. He was restless and noisy at night, fretful and irritable by day, and had lost his appetite. There was no history of diphtheria, sore-throat, or other illness. On admission he was healthy-looking and well nourished, but seemed drowsy and listless and complained constantly of left-sided headache, but did not vomit. He had complete left-sided facial paralysis. The palate was unaffected and the voice unchanged. There were neither signs nor history of middle-ear disease. The optic discs were normal. There were marked tremors and ataxy of the hands on voluntary movements and also tremors of the legs on standing. When in the erect position there was considerable lumbar lordosis. He walked with his legs apart and staggered as in cerebellar disease. He could not rise from the sitting position without resting his hands on his knees as in pseudo-hypertrophic paralysis. The knee-jerks were absent. There was no wasting of any part, but only general muscular weakness. The treatment was by small doses of biniodide of mercury. After two weeks he began to improve; the tremors and ataxy and the facial paralysis gradually disappeared He became able to sit up and rise from the ground without difficulty, but the knee-jerks were still absent. By Sept. 7th the knee-jerks had returned and now he was in every respect well. In commenting on these cases Dr. Guthrie remarked that, although the symptoms seemed dissimilar, the disease—polyneuritis—was the same. The etiology of the disease was uncertain. One naturally thought of diphtheritic paralysis, although a history of primary diphtheria was absent, for many cases of diphtheritic paralysis occurred without any such history. A stronger objection to this diagnosis was the absence of palatal paralysis. The soft palate was, he believed, invariably affected in paralysis following faucial diphtheria. It might escape or be attacked later in cases of vulvar or cutaneous diphtheria. But the patients were both males and there was no history of cutaneous diphtheria, which could not have escaped notice had it occurred. It was suggested that a modified attack of influenza in unprotected subjects might account for the symptoms. For influenza in its primary form was essentially a disease which attacked the nervous system and left behind it effects which simulated those of almost every nervous affection known. Syphilis, alcohol, and other toxic agents could be excluded.—Dr. JAMES TAYLOR expressed agreement with Dr. Guthrie's diagnosis.—Dr. NORMAN KERR would like to know the atmospheric conditions when the attack began.—In reply Dr. GUTHRIE said that as to climatic influences the illness of one child commenced in May and lasted till August. The illness of the other began in September. The hot months were well known to be associated with diseases such as infantile paralysis and cerebro-spinal meningitis in children.

Mr. ROUGHTON showed a woman, aged thirty years, suffering from a Primary Chancre of the Lower Lip. When first seen (two months after the first appearance of the sore) there was a yellow, circular, raised, indurated ulcer the size of a shilling, but there was no enlargement of the sub mental glands. Glandular enlargement appeared soon afterwards, but was very much less in amount than that usually seen in such cases. Mr. Roughton commented on the importance of early diagnosis in cases of erratic chancre, and pointed out that there was a risk of their true nature being overlooked.—Mr. EASTES had seen similar cases. In one the swelling of the face measured three inches across from the lip to the chin, the primary sore near the angle of the mouth being little more than a crack.

Dr. ALFRED EDDOWES presented a man, aged thirty-one years, suffering from Rodent Ulcer of the face and ear of four years' duration. The age of the patient, the fact that the ulcer, now an inch wide, had never been treated surgically, and the clean cut appearance of its edges, were the chief points of interest. The patient, whom Dr. Eddowes had only seen a few days ago for the first time, was at present opposed to operative treatment; but Dr. Eddowes had lived

Hosted by Google

long enough to see sad relapses in cases which had been treated years ago by very skilful surgeons. He did not scrape in such cases, but always adopted the plan of burning the tissues with a cautery of low temperature to the extent of a quarter of an inch in all directions. He expected in this case that the large hole would become filled in a few days with granulation, and that there would be an excellent flat scar with minimum disfigurement.

Mr. GEORGE STOKER showed Cases Treated by Oxygen Gas. Case 1. A woman, aged fifty-one years, has had ulcers on her legs for seven years. They began by an abrasion of the skin. The patient had suffered great pain. She was treated at Chelsea Dispensary and at St. George's Hospital. The ulcers never healed. When she came into the Oxygen Home on Dec. 28th, 1896, she had three large and two small ulcers. She was treated with equal parts of oxygen and purified air. In eleven days the two large ulcers healed, the other three being reduced in size, but still open. On Jan. 25th, 27th, and 29th these latter were inoculated with staphylococci. On Feb. 4th two were healed and the third one nearly so. Case 2. A woman, aged thirty-eight years, was admitted to the Oxygen Home on Oct. 21st, 1896. Just before Christmas, 1894, the leg first became bad, she was then treated as an out-patient at St. George's Hospital. In April, 1896, she went again to St. George's Hospital. Since that time till October 1896, she had been laid up at home. She had suffered constant pain. She was treated with equal parts of oxygen and purified air. On Nov. 23rd the two smaller ulcers were quite healed. On Dec. 21st the large ulcer had almost healed, only two small places remaining unhealed as large as threepenny and sixpenny pieces respectively. On Jan. 22nd, 1897, the small places still remaining unhealed they were inoculated with staphylococci. On the 25th, 26th, and 27th the inoculations were repeated. On the 29th the patient was discharged cured.—Mr. GEORGE STOKER and Mr. GEORGE DONEEN gave a bacteriological report on the above cases. Case 1. Before the oxygen treatment was begun a cultivation was taken from the ulcer on agar agar. After incubation it was found to contain a pure growth of staphylococcus pyogenes citreus. N.B.—Out of upwards of sixty cases examined this was the first and only one in which a pure growth of staphylococci was found previous to the oxygen treatment being begun. Case 2. The cultivation taken before the oxygen treatment was begun was found to contain bacillus fluorescens and staphylococcus pyogenes albus. The former disappeared after a few weeks. The above examinations are especially important as showing the relation between oxygen and staphylococci in promoting healing. In Case 1 we found staphylococci in an ulcer that showed no disposition to heal till oxygen was applied, and in both cases a stage was reached in which oxygen ceased to cause healing till fresh staphylococci were introduced by inoculation. It would seem from this that there is some collaboration necessary between these two factors, oxygen and staphylococci, in order to promote healing by this system of treatment.—Dr. SOLOMON SMITH said that, however open to criticism the oxygen treatment might appear, it at the least was worthy of careful investigation. The bacteriological observations which were recorded by Mr. Stoker were of very great interest. It was certain that wounds often healed well when bathed in pus which must be crowded with micro-organisms, in illustration of which he instanced the "laudable pus" of pre-antiseptic days. They were all aware of the septic evils so often associated with certain forms of streptococci, but what Mr. Stoker had stated in regard to the "healing" effect of pure cultures of staphylococci seemed to him to far outweigh in importance all that had been said about oxygen. In every out-patient room there were cases healing well under various forms of treatment—under Unna's paste, for example—which were certainly not aseptic, and he urged that careful examinations of the discharges in such cases should be made, with the object of ascertaining whether in them also a similar preponderance of staphylococci presented itself.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

The Menopause viewed from a Gynæcological Standpoint.

A MEETING of this society was held on Feb. 5th, the President, Mr. W. BRUCE CLARKE, being in the chair.

A discussion on Disorders associated with the Menopause opened with the reading of a paper by Dr. AMAND ROUTH, in which he first dealt with organic lesions common at the menopause, leaving psychical conditions to subsequent speakers, though they could not be ignored in actual practice if success in treatment was to be attained. He showed that the vulva was apt to become affected with local hyperæsthesias, such as pruritus pudendi, which was a symptom of many diverse conditions. Thus it might be due to a pure neurosis, to reflex causes, such as early cancer of the cervix, to mucous polypus, to prolapsed ovary, or to kraurosis, local rashes, dirt, parasites, vaginal or uterine discharges, irritating urine, as in cases of cystitis, acidity, gout, or diabetes. Kraurosis vulvæ and diabetic pruritus were described, with their appropriate treatment. Intra pelvic climacteric affections were next considered and the influence of the ovarian "internal secretion" was discussed, with the probability that the diminution of this influence accounted for some of the climacteric phenomena. The hæmorrhages of the menopause were then dealt with. If vaginal and cervical disease could be eliminated the uterus should be digitally explored after rapid dilatation, and a means of diagnosis and immediate treatment thus afforded. If this were done as a matter of routine early cases of fundal cancer could be very easily dealt with by vaginal hysterectomy, which was now an operation almost without mortality, though, owing to the cases being seen somewhat late, the final results were still unsatisfactory. Functional pelvic and constitutional troubles were then considered, and it was pointed out how advisable it was to avoid local treatment at this age unless it were imperative. The subjects of tachycardia and "flushings" were discussed. The treatment was most successful by combined nerve sedatives, anti-spasmodics, and purgatives. All such patients needed much encouragement, and in the absence of serious organic disease should be assured that they would soon emerge from their present trials and become active and possibly even robust and vigorous.

Mr. CHARLES TUKE discussed the subject from the psychological aspect. He pointed out that the neuroses seen show many gradations from nervous irritability with effects on the character and temper to fully developed insanity, which has a tendency in a large proportion of cases to melancholia or a delusional insanity, less frequently to mental weakness, and rarely to general paralysis. The treatment advocated was change of air and scene, removal from friends, together with attention to the bodily health. By these means many patients were restored to mental and physical vigour.

Dr. HARRY CAMPBELL observed that the nervousness of the climacteric is not strictly synchronous with the menstrual irregularities of this epoch, that a wave of nervous irritability comes over the woman before the commencement of the irregular menstruation and lasts for some time after its disappearance. The same is true of puberty. He contended that practically every woman suffered from depression of spirits at the climacteric. He referred to the frequency of post-climacteric monthly manifestations. He had observed them in over 100 cases, and in one case had traced them to beyond seventy years of age. He was inclined to believe that the menstrual rhythm continued in all women to the end of life.

Dr. J. A. MANSELL MOULLIN said that Dr. Routh had dealt exhaustively with the local troubles of the vulva commonly met with at this period. One symptom to which Dr. Moullin drew attention was dyspareunia. Cases occurred where the introitus was small, the mucous membrane of the vulva had already acquired that smooth and glazed appearance characteristic of senility, and around the ostium vaginæ were certain well-defined, circumscribed spots extending forwards and involving the meatus urinarius and the urethral canal. These were exquisitely tender and bathed in a muco-purulent discharge. This condition had been termed lupus minimus, which Dr. Moullin regarded as a misnomer.

Dr. HENRY SUTHERLAND remarked that he did not believe that the change of life *per se* had much influence in causing insanity at this period. His data were based on an investigation of 100 cases of insanity at this period. The form of insanity was melancholia in 67 per cent, mania 24 per cent., dementia 4 per cent., epileptic insanity 3 per cent., general paralysis 2 per cent. The prognosis was usually favourable, 40 per cent. recovering. The duration of the attack varied from three months to three years, after which period the

Hosted by Google

outlook was hopeless. Dr. Sutherland added suggestions as to treatment.

Mr. MCADAM ECCLES alluded to two points of interest to the surgeon in connexion with the menopause: (1) as to operations at this period, and (2) as to whether the involution of the sexual organs had any effect on mammary cancer.

Dr. FORBES-ROSS referred to the insanity occurring in the male sex at a period corresponding to the climacteric, and that some derangement of the abdominal organs was associated with the mental disorder.

Dr. MCCANN said he quite agreed with Dr. Harry Campbell as to the continuance of the menstrual phenomena after the blood loss had ceased, as the discharge of blood might be looked upon as an accidental concomitant of menstruation, examples of so-called white menstruation being not uncommon. He pointed out that cases of early menopause might be confounded with a condition which he believed to be more frequent than was generally accepted—viz., transitory superinvolution of the uterus associated with amenorrhœa and climacteric signs and symptoms. He described a case where a patient, aged thirty-two years, having nursed her child for eight months, had a period of complete amenorrhœa for fourteen months after the cessation of lactation. She complained of marked flushings and other disturbances associated with the menopause. On vaginal examination the uterus was found to be small, the cavity measuring two inches, and there was contraction of the upper portion of the vagina (a well-known sign after the menopause). Six months later menstruation returned with increased size of the uterus, and the patient had continued to menstruate regularly. She was not anæmic. He had seen in addition two other cases closely resembling the one described.

Dr. CHAPMAN advocated belladonna in the treatment of tachycardia at the menopause.

Mr. CHARLES TUKE disagreed with Dr. Sutherland's opinion and thought that the climacteric was frequently associated with a mental "breakdown." He had seen acute mania develop after the removal of a mammary cancer at the climacteric. He thought that mental and nervous symptoms were more frequent in the upper classes. He agreed with Dr. Forbes-Ross in thinking that there were analogous mental disorders in the male corresponding to the climacteric in the female.

Remarks were also made by Dr. CAMPBELL POPE.

Dr. ROUTH, in reply, expressed his sense of the value of the discussion. He was familiar with the painful granular areas of the vulva. In reply to Mr. Eccles, he believed that acute mania was more common after ovariotomy at the menopause than at other ages. Ovarian "internal secretion" was a very interesting subject. The cure of osteomalacia by oöphorectomy was explicable by the chemical changes produced in the blood, but the very recent recovery of recurrent mammary carcinoma after oöphorectomy was so far inexplicable. He had not seen any cases of temporary superinvolution described by Dr. McCann and was much interested in the cases.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The Royal Commission on Vaccination.

A MEETING of this society was held on Jan. 15th, Dr. G. P. BATE, President, being in the chair.

Dr. F. T. BOND, of Gloucester, read a paper entitled, How shall we Legalise the Recommendations of the Royal Commission on Vaccination? While paying a high tribute to the ability and character of the members of the Commission he expressed his regret at the absence from their report of summary, index, insets, or headlines, as well as of any clear indication of the practical policy they would propose. There were but three "recommendations"—viz., the discontinuance of criminal procedure and of repeated penalties, the more effective inspection of common lodging houses, and the supervision of tramps who might be vehicles of infection—and perhaps a fourth as to the more general supply of calf lymph. They "thought" that the age for primary vaccination might be extended from the third to the twelfth month, as in Scotland—except in the presence of an outbreak, though they did not indicate how such exceptional procedure should be enforced; that vaccination might be oftener postponed on account of ill-health or insanitary surroundings; that greater care should be taken to avoid wound poisoning, and the inspection delayed until the tenth or twelfth day, when the effects of such accidents were manifested (which should be treated by the public vaccinator); and that the Local Government Board should have power to compel the establishment of small-pox hospitals. They were "of opinion" that vaccination should not be optional and that the State should "promote" it, though by what form of pressure or suasion they did not say; and persons suffering loss by isolation or exposure to infection should be compensated by the local authority; while they "believed" that risks and opposition would be lessened if vaccination and inspection were, "as a rule," carried out in the home. They admitted the value of isolation, but only as an auxiliary measure, and made a passing reference to "sanitation," and, "believing" in the protection afforded by vaccination and re-vaccination, "considered" the danger incident to vaccination "insignificant" in comparison. But while piously wishing for the extension of vaccination, which the State should not only "promote" but "require," they would so far sympathise with "honest or conscientious" objections as to enable any parent to evade it by a simple statement before a magistrate or vaccination officer, at the same time dropping procedure against the merely negligent by the repeal of existing Acts. Dr. Bond maintained that it would be better to suspend, for a limited period of, say, five years only, the harsher and more obnoxious clauses, substituting "orders" of a tentative and temporary character. He considered that in order to distinguish "honest" objection from indifference the summons should be taken out as hitherto and the costs paid by the objector, who by a public declaration in court might obtain an exemption, to be entered in the register of the vaccination officer, but to hold good only until the child reached school age or small-pox broke out in the district. It would be far easier to enforce vaccination of school children than of infants, and inspection of their arms would discover the "sham" vaccinations which worked such evil, and he thought that re-vaccination might be required on leaving. The difficulty in tracing defaulters, through change of residence, if not wilful mis-statement of place of birth, would cease, since children were now compelled to attend some school, and their arms would be evidence of vaccination or of its omission. He considered that certificates should testify not merely to alleged "success" but to the number and area of the vesicles, which should be entered in the register for future reference. He approved of home vaccination by the public vaccinator, but could not agree to every practitioner being constituted one. He strongly urged the transference of vaccination from the guardians to the sanitary authorities on whom all measures for the prevention of disease and control of epidemics already devolved, pointing out that the difficulties apprehended by the commissioners in respect of overlapping authorities were imaginary and owing to a confusion between unions and sanitary districts. This would necessitate and hasten the much-needed re-organisation of sanitary administration and the better adjustment, consolidation, &c., of areas, with the appointment of whole time and independent medical officers of health, who should be brought into closer touch with the Poor-law medical officers, vaccination, registration, and other officers. The post of chief vaccination officer would be attached to that of superintendent-registrar over revised and coincident areas. He thought that if a short statement of the benefits of vaccination with evidence were affixed to the notice given at the registration of birth, and the public vaccinator were between six and twelve months later to visit the parents at their home by tact and suasion both the objections and the apathy might mostly be overcome. After summarising the conclusions embodied in the report, Dr. Bond asked the support of the society for the following recommendations—(1) to allow public vaccinators to offer calf lymph as a substitute for human lymph in all cases in which it might be preferred; (2) to extend the period within which a child was at present required to be vaccinated; (3) to provide for the medical treatment of children after vaccination, so far as might be necessary to ensure good results; (4) to provide for the more effectual supervision of tramps and common lodging houses; and (5) to ensure better means than now existed for enforcing the proper accommodation in every sanitary district for the isolation of small-pox and other infectious diseases.

The discussion of the paper was adjourned until the next meeting.

Hosted by Google

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Specimens.—Serum Diagnosis of Typhoid Fever.

A MEETING of the pathological section was held on Feb. 4th, Mr. F. T. PAUL being in the chair.

The following specimens were exhibited:—

Dr. GEMMELL: (1) Calcareous Deposit in the Broad Ligament; (2) Tubo-ovarian Abscess; and (3) Adenoma Uteri.

Mr. ROBERT JONES: (1) Omental Adhesions after operation for Ascites; and (2) Osteo-Sarcoma of the Femur.

Dr. BARENDT: Lichen Ruber Planus-efflorescence.

Mr. R. A. BICKERSTETH: (1) Villous Tumour of the Bladder; and (2) Hypertrophy of the Prostate.

Mr. LARKIN: (1) Carcinoma of the Submaxillary Salivary Gland; and (2) Fibroma of the Skin.

Dr. LESLIE ROBERTS: (1) Angioma Serpiginosum; and (2) Lymphangioma Capillaræ Varicosum.

Dr. GIVEN: Acne Keloid.

Mr. R. PARKER: Sarcoma of the Popliteal Space.

Dr. JOHN ROBERTSON (St. Helens) read a paper on Serum Diagnosis of Typhoid Fever in which he gave a brief review of the observations of earlier workers, and especially those of Pfeiffer and Kolle, Gruber, Durham, Widal, and Delépine. He showed the method of demonstrating the special action of typhoid blood serum on the bacillus of typhoid fever (*a*) in test tubes, and (*b*) as hanging-drop preparations under the microscope and spoke of the advantages of the latter method for clinical purposes. He explained the method of collecting blood in sterile, large-sized vaccine tubes and described the special apparatus used for collecting. The preparation of the typhoid culture was next reviewed and the necessary dilution of the serum. The results obtained by various observers and those obtained in St. Helens during the past six months were compared. The value of the early diagnosis of typhoid fever to the patient and for public health purposes was emphasised and the use of known typhoid serum in identifying the typhoid organism was commented on.

After a few remarks from the CHAIRMAN Professor DELÉPINE emphasised the importance of using fresh cultures of the bacillus typhosus. He had noticed that old cultivations had of themselves a tendency to clumping. To obtain such cultures the bacillus was grown on solid medium and fluid cultures were made from day to day as required. It was important to avoid the slightest contamination, and he considered a magnifying power of 300 diameters sufficient to observe the reaction.

Mr. H. E. DURHAM (London) drew attention to a few historical facts contrasting the old observations of Metschnikoff and others on growth in immune serums with the sudden and immediate direct action of serums on appropriate microbes. Bordet had not attached sufficient importance to the "clumping action" of serums to lead him to the study of the inter-actions of various microbes and serums; the positive result in Bordet's phenomenon is arrived at when all microbes are degenerated into coccus-like bodies. He showed that a positive reaction is present between organisms which are otherwise regarded as specifically different, so that a positive result in testing microbes is not absolutely conclusive as to species; the positive reaction of Gärtner's bacillus enteritidis (with typhoid serum discovered in Professor Gruber's laboratory) was cited as a case in point, as well as the reactions of certain races of vibrios. At the Wiesbaden Congress in April, 1895, Professor Gruber and he had demonstrated that animals which had received a single immunising dose of cholera more than a year previously still showed a specialised action upon cholera vibrios, but not on other kinds. The use of serum reactions might be summed up under three headings:—(1) recognition of kinds of bacteria and, to a certain extent, of the virulence of bacteria; (2) recognition of kinds of serum and their potency; and (3) recognition of disease in man clinically by the reaction of the serum on known bacilli. It was pointed out that positive reaction was not strictly specific. The two kinds of immunity—viz., antitoxic and anti-bacterial—must always be distinguished. Anti-bacterial serums had great clumping power on appropriate microbes, yet might be entirely without antitoxic power. Antitoxic serums always had some anti-bacterial power, but in no relation to the antitoxic power. Highly acute infective diseases (mainly toxic) as diphtheria or cholera required therapeutically an antitoxic serum. In more chronic diseases such as typhoid fever an anti-bacterial serum might be sufficient; present results with anti-typhoid serum (which is mainly anti-bacterial) were not unpromising. The present anti-streptococcic serum as tested by its clumping power was not highly potent anti-bacterially; it was suggested that probably more uniformly good results would be obtained when a higher potency of anti-bacterial power had been obtained. For anti-bacterial purposes it would be possible to gauge the dose of serum required by estimating the dilution which occurred in the patient's body. As regarded the clinical value of typhoid sero-diagnosis, observation showed that a positive result was not always obtainable in typical cases of typhoid fever. This was not curious when it is remembered that the degree of immunisation or production of "antibodies" is relatively slight in man when contrasted with an animal which has received a large number of injections. A warning was raised against a positive reaction from the fact of the inter-action of typhoid and Gärtner's bacillus, an instance being cited of positive reaction occurring after a nondescript attack resembling typhoid fever somewhat, but which yet might have been due to a bacillus similar to that of Gärtner. Mr. Durham then gave a demonstration of photographic lantern slides (many of which were of historical interest as having been prepared in the summer of 1895) to show the macroscopic and microscopic effects of various serums, illustrating the want of absolute specificity in the reaction and the abnormal growth in serums (coccus chains). A series of tubes were shown to draw attention to the action of typhoid fever serum and the serum of typhoid fever patients on the bacillus enteritidis of Gärtner. Blachstein's "Chrysoidin" cholera reaction was also exhibited.

Dr. GRÜNBAUM emphasised the importance of dilution of the serum and recommended that it should be accurate. On account of the action of normal serums and those of other diseases a time limit is also necessary. He had observed similar effects to those of the Canadian observers from the variability of virulence, but proper dilution obviated any confusion. The action of typhoid serum on other micro-organisms was interesting, but did not affect its diagnostic value. That the reaction should be present from about the third day of the disease was in accordance with experiments on animals whose blood first showed an agglutinative action generally about the third day after the first inoculation. He had not come across any case of enteric fever in which the reaction was not present at some time. In one so-called abortive case it was also found. The method does not depend on the motility of the pathogenic organism, as was shown by the agglutination of a diplococcus from a scarlet fever case by serum from another scarlet fever patient. He hoped that the results of investigations now proceeding would enable him to isolate the micro-organisms of other diseases as well as facilitate their diagnosis, although in some cases there were difficulties arising from mixed infection.

Dr. N. E. ROBERTS showed a hanging-drop specimen of typhoid bacillus culture, to which the serum of a typhus fever patient had been added four hours previously (dilution 1 in 20). The bacilli were motile and showed no clumping. In contrast with this, two specimens of enteric serum treated in the same manner and at the same time gave the following results. The active darting and gliding movements were lost in a few minutes and clumping was marked in one case in half an hour and in the other case in a little over that time. He was of opinion, from what he had observed, that there seemed to be a decidedly specific quality in the blood of an enteric patient tending to inhibit the movements of the typhoid bacillus in broth culture and also to the formation of clumps. What had struck him as most remarkable—in some cases it was startling—was the almost immediate cessation of the movements of translation on the field, and he was disappointed to find that Mr. Durham did not seem to attach much importance to this. In his first observations on typhus blood he obtained the reaction, but on diluting the serum as above it failed to give it. He asked what was the intimate meaning of this reaction. Was it associated with immunity? If so, was it proportional to immunity? As physician to the Liverpool City Hospitals he had about 300 cases of typhoid fever under his care every year. During the five years he had charge of the South Hospital the typhoid fever cases were not far short of 1300. He found that about 4 per cent. of these cases relapse, by which is meant that a patient undergoes a fresh attack of typhoid fever. This is excluding all doubtful cases and those of mere recrudescence. He would take an ordinary case of relapse as an example. A patient had a severe attack of typhoid fever lasting four weeks. The temperature became settled

Hosted by Google

and the patient was in a fair way towards convalescence when in a week or ten days he started a fresh attack—a new enteric process. That patient was not immune against typhoid fever surely. At all events he was not immune in the sense that a typhus fever or small-pox patient was after an attack of either of these diseases. He was not protected against the disease. The relapses at the City Hospital resulted in a two weeks' fever as a rule. Sometimes after the first relapse the patient underwent another attack after an interval perhaps, and rarely a third relapse had been described. This would appear to show that protective immunity, if attained at all, must come on very late indeed in the history of a patient. But it was said that the serum reaction came on very early, some observers saying that they found it in the seventh or eighth day of the disease. If the phenomena of relapses therefore were of any value on this point the serum reaction did not appear to be proportional to immunity attained. On the other hand, that immunisation was going on during the enteric process appeared to be probable, as evidenced by the fact that it was comparatively a rare occurrence for a typhoid fever relapse patient to succumb to the attack. It was a curious fact that a patient who had just emerged from a severe attack of typhoid fever, perhaps lasting for four weeks, and who, weak and prostrate from the effects of it, was very badly equipped to weather another storm, should in the large majority of cases go through his second attack without "turning a hair," to use a vulgarism. He had a moist tongue, looked well, slept well, had a fair pulse, and was comfortable. That was the usual story of a typhoid fever relapse. Further, the temperature might be high, even higher than in the primary attack. This latter fact seemed to throw a sidelight on the question of the importance of mere temperature in typhoid fever. It would, therefore, appear that for some reason or other the toxæmia in relapses was very much modified and the recoveries were much more numerous than in primary typhoid fever. The explanation of this appeared to the speaker to be that a slow immunisation was going on from an early date in the history of the case, which, although not sufficient to protect the patient absolutely, was sufficient to modify the severity of the attack. To sum up, Dr. Roberts was of opinion that immunity of a protective quality came on very late in typhoid fever, if at all, but that an immunisation was going on all along.

Professor BOYCE said how indebted they felt to the great authorities who had come that evening to render this debate on the diagnosis of typhoid fever one of the most important which had occurred up to the present time. They had had the privilege of hearing from Dr. Robertson, Mr. Durham, Dr. Roberts, Dr. Grünbaum, and Professor Delépine the results of their most recent investigations. No one would question the value of the serum diagnosis of typhoid fever, and the simplicity of the test made it incumbent upon all to apply it. They had now only to send a small capillary tube of blood to the pathological laboratory to receive an opinion. The discussion had brought out the share that the several speakers had taken in this most important investigation, and he gladly seized this opportunity of claiming for Dr. Grünbaum priority as regards Widal's observations. Professor Boyce agreed with the observations of Dr. Roberts, who was working in the pathological department upon the reaction of typhus serum.—Mr. DURHAM stated that he obtained a reaction with the bacillus enteritidis. Dr. Campbell and himself had tried the reaction with a closely allied bacillus, which was invariably associated with a very severe form of dysentery met with at the Rainhill Asylum, but they had not obtained clumping with typhoid serum.

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases.—A Plea for more Accurate and Systematic Feeding of Infants.

THE fifth ordinary meeting of this society was held on Feb. 3rd, the President, Dr. A. H. CARTER, and afterwards Dr. FOXWELL, being in the chair.

Mr. MORRISON read notes on a case of Fracture of the Clavicle by Muscular Contraction.

Dr. FOXWELL showed a case of Early Disseminated Sclerosis in a young man. No similar disease or neurotic predisposition could be traced in the sufferer's family. The disease was attributed by the patient to hard work in a stooping position, and the first symptom was vertigo of increasing intensity and becoming so severe as to cause the patient to fall. The present symptoms and signs were extremely spastic gait and spastic tremor of the legs while standing, with marked preservation of volitional power and disappearance of the tremor in the recumbent posture, spastic expulsion of the urine, and only a very little tremor of the hands near the completion of delicate coördinate movements. Affection of the speech was doubtful and not recognised by the patient and his friends, but there was a slight nystagmus on strong lateral conjugate deviation, chiefly to the right side.

Dr. SAUNDBY showed the Kidneys from three cases of Diabetes Insipidus in which death had ensued from uræmic coma. The first pair, which showed well-marked hydronephrotic sacculation, came from a case published at length in the *Practitioner* of January, 1895. The patient was a young man who had suffered from polydipsia and polyuria all his life, but during his final stay in hospital the amount of urine was less—between five and six pints—and the urea only 200 grains daily. He died comatose on the eighteenth day after admission. The kidneys shown next were from the body of a young man who had had polydipsia and polyuria for four years. When seen last September his urine was only from five to six pints daily and contained 300 grains of urea. He died from coma on Jan. 11th. The kidneys were sacculated and wasted, the microscope showing sub-capsular interstitial nephritis. The last pair of kidneys were from the body of a woman who had died in the General Hospital from uræmic coma. For a month before admission the patient had suffered from thirst and polyuria. The urine contained a little albumin, and varied in amount from five to seven pints. The urea was estimated soon after her admission only, and was then stated to be 700 grains. These kidneys showed no trace of sacculation, but the cortical substance was atrophied, and the microscope showed similar sub-capsular interstitial nephritis, as in the former case. Dr. Saundby referred to the cases published in "Beale's Archives" in 1861 and 1862 by Dr. Strange of Worcester and Dr. Eadie, but he remarked that the lesson contained therein had been unheeded by that generation and had had no definite significance for himself, although well known to him, until his first fatal case two years ago. The point he wished to bring home was that cases of diabetes insipidus are liable to suffer from secondary wasting of the kidneys, causing fatal uræmia, and that this is common enough to require modification in the current prognosis, which regards this disease as but little dangerous to life, although generally incurable.

The PRESIDENT read a paper entitled "A Plea for more Accurate and Systematic Feeding of Infants," in which he insisted that greater attention should be given to the composition of infants' food from whatever source it was derived. He discussed the composition of human milk, the variations usually met with in practice, and the best means of overcoming them. Reasons were adduced for the preference of cow's milk as a substitute for human milk, and tables were submitted for more accurate adjustment of milk to infant's requirements. It was pointed out that by more careful feeding, accompanied by periodical weighing of infants at short intervals, much might be done to prevent serious gastro-intestinal disorders.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 28th, the President, Mr. RECKLESS, being in the chair.

A resolution of congratulation to Lord Lister on his elevation to the Peerage was passed with acclamation.

Mr. SIMEON SNELL introduced the following clinical cases: (1) An infant with Anophthalmus and Cyst of the Right Lower Eyelid; (2) two instances of Rupture of the Choroid; (3) Sub-conjunctival Dislocation of Lens, with Rupture of the Globe above; (4) Retinitis Pigmentosa with an unusual amount of Pigment (the patient's grandfather on the mother's side was affected); and (5) Herpes Ophthalmicus. Mr. Snell then related the particulars of a case of Distended Frontal Sinus. The patient had undergone a similar operation fifteen years previously and had remained well for

Hosted by Google

twelve years. About three years since a tumour at the upper orbital region re-appeared and increased until the patient again came under observation in November last. There were then considerable prominence and outward displacement of the eye. The sinus was opened from the orbit and a drainage-tube passed into the nose. Stereoscopic photographs of the patient before and after operation were shown.

Dr. ARTHUR HALL demonstrated the presence of Borax in the Urine from Cutaneous Absorption.

Mr. ARCHIBALD YOUNG showed a case of Molluscum Fibrosum.

Mr. CUFF showed cases illustrating some of the Various Lesions of the Joints and Bones occurring in the later stages of Congenital Syphilis and made remarks upon them. They included forms of sclerosing osteitis and necrosis of the tibiæ, humeri, ulna, and radius; enlargements of the epiphyses of the long bones and in one case lengthening of the affected bone (tibia). Necrosis of the frontal bone was also present in one case. The joint lesions included the usual ones found in syphilis and were in the main symmetrical. The bone lesions, on the other hand, were asymmetrical, contrary to what is usually taught.

Dr. SINCLAIR WHITE showed—(1) a lad, aged eleven years, with Atrophy of the Thenar Eminence and Bulbous Enlargement of the Tips of the Thumb and Index Finger due to implication of the median nerves in the callus of a fracture of the humerus; and (2) a large Calculus removed from the Prostatic Urethra of a Boy. The calculus had a uric acid nucleus which, becoming impacted in the prostate, had increased in size and produced retention of urine.

The PRESIDENT, Dr. KEELING, Mr. ATKIN, Mr. PYE-SMITH, Dr. SINCLAIR WHITE, Mr. SNELL, Mr. CUFF, and Dr. EASTES made remarks.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Spontaneous Rupture of the Female Bladder. — Ileo-colic Intussusception: Enterostomy; Recovery.—Lateral Sinus Pyæmia. — Empyema of the Maxillary Sinus. — Some Instruments of Local and Historical Interest. — Diphtheria.—Exhibition of Specimens.

A MEETING of this society was held on Jan. 15th, Dr. BRAITHWAITE being in the chair.

Mr. E. O. CROFT read notes of a case of Spontaneous Rupture of the Female Bladder. A widow, aged thirty-eight years, was admitted into the Hospital for Women and Children at Leeds suffering from hæmorrhoids. The rectal symptoms had existed for four or five years, but there was no history of other illness and the family history was good. On Dec. 5th, 1896, the hæmorrhoids were removed by operation under ether. There was no subsequent retention of urine and progress was normal until Dec. 14th—i.e., eight days after the operation, when the patient complained of abdominal pain and stated that she had felt a twitch in her body while reaching to move her pillow. Abdominal pain and distension continued and the urine diminished in quantity, though a few ounces were drawn at intervals by the catheter. There was no rise of temperature. The patient gradually sank and died on Dec. 17th. At the necropsy a large quantity of urine was found in the peritoneal cavity. There was no peritonitis, adhesion, or evidence of tuberculous disease or abscess in the pelvis or abdomen. The bladder was empty. On the upper and posterior surface of its peritonial aspect, in the middle line, was found a long, somewhat oval ulcer measuring about one inch by half an inch at its widest part. From its thickened edges it appeared to be of old standing. The base was formed of the mucous membrane of the bladder, and in its centre was found a small circular aperture about one-sixth of an inch in diameter. The specimen has been preserved for further examination and a fuller report will be subsequently published. Mr. Croft drew attention to the diagnosis being rendered obscure by the fact that the bladder continued to hold some urine after the perforation took place, and also to the peculiarity of the ulceration taking place on the outer surface of the bladder.

Mr. LAWFORD KNAGGS described a case of Ileo-colic Intussusception in which Enterostomy was performed for Obstruction. After an interval the intussusception, which had been diagnosed subsequently to the enterostomy, was reduced through a lateral incision, and later the artificial anus was treated by enterectomy. A second case, in which the intussusception was of colic variety, had been reduced through a median incision after the failure of inflation. Both cases had done well. Some circumstances observed in connexion with the first formed the basis of some remarks on the mechanism of spontaneous reduction.

Mr. MAYO ROBSON read a paper on a case of Lateral Sinus Pyæmia in which he had removed part of the lateral sinus and ligatured the internal jugular vein in the neck. The patient, who was extremely ill at the time of the operation, and was suffering from a high temperature with frequent rigors, made a slow but good recovery and was now quite well. The wound in the neck healed by first intention and the trephine opening, which had to be packed, healed by granulation.—A discussion followed in which Mr. WALKER, Dr. BRONNER, Dr. WHITEHEAD, and Mr. HOLLINGS joined.

Dr. ADOLPH BRONNER read notes on a Case of Empyema of the Maxillary Sinus, in which the only symptom complained of was parosmia. He drew attention to the frequency of diseases of the accessory cavities of the nose after influenza. In most cases the symptoms of disease of the maxillary sinus were discharge from the nares, parosmia, and slight pain. In the case recorded parosmia was the only symptom. The sinus was opened through the alveolar process and the opening kept patent by a gold pin attached to the false teeth. This was the most successful method of treating these cases.

Mr. C. J. WRIGHT read a paper upon Some Instruments of Local and Historical Interest and exhibited a number of specimens from the Medical School Museum. He referred to the very ancient examples found in Pompeii and other parts of Italy as illustrating more or less perfect forms of those in use at the present day—viz., catheters, probes, dissectors, scalpels, trephining instruments, uterine sounds and hooks, and anal and vaginal specula. These were seen recently in this country amongst the valuable collection exhibited by Messrs. Oppenheimer and Co. at the annual meetings of the British Medical Association in 1894-95. The Donaria—or votive offerings to the medical deities—chiefly of terracotta, in this collection evinced much anatomical and pathological accuracy. Coming to later times, plates in Scultetus' "Armamentarium Chirurgicum" (seventeenth century) of Hey's saws and Weiss's dilator were found, of which the forms at present in use are mere developments, and a drawing from the same work showed that suction for cataract was practised before that time. The following were then exhibited: Stethoscope (the original form as depicted in Laennec's book—about 1816, and another later form, with stopper); Hey's Saws (various forms—1803-1810); Aston Key's Lithotomy Case (1824); straight grooved Staff and Beaked Knife, Blunt and Cutting Gorgets, &c., according to Cheselden; Knives and Blunt Gorgets used by the late Samuel Smith of Leeds; and a Pair of Bone Forceps which belonged to Liston, marked with his initials, "R. L." The jubilee of anæsthesia rendered important the earlier modes of administration of ether. A glass receiver enclosing sponges was shown, corresponding probably with that described by Dr. Wm. Squire[1] in 1896 as the one used at the first administration of ether, at which he was present, in December, 1846; also a Sponge covered with mackintosh, used upon the re-introduction of ether to England in 1872, and Allis's Cage Inhaler for open administration, brought from Philadelphia in 1875 and still used in America. The obstetric examples were Smellie's Forceps (covered with leather, 1754); Denman's short straight Forceps (1794); Davis's short curved Forceps (about 1841); Pair of Crotchets with English lock (Smellie's); and another Pair of Crotchets, with sheath for guarding one point (Davis's). Some "Moxas"—an old form of escharotic and counter-irritant for burning into the subcutaneous tissues and consisting of pith and cotton soaked in potassæ nitras—completed the list. Mr. Wright concluded by appealing to members for contributions to his collection.

Dr. GORDON SHARP read a paper upon Diphtheria and dealt with Hansemann's views, and showed that the percentage of cases in which the Klebs-Löffler bacillus is not found is few in number. Further, that the presence of the bacillus on normal mucous membrane is accidental, and the same may be said of the tubercle bacillus or other micro-organism. The presence of other micro-organisms in diphtheria was next spoken of, and Dr. Sharp gave it as his opinion that

[1] Brit. Med. Jour., Oct. 17th, 1896, p. 1143.

Hosted by Google

staphylococci and streptococci hindered the production of the organic acid and so increased the malignancy of the malady. His opinion was that these last-named microbes did not produce a membrane like that seen in a well-marked case of diphtheria evident to the clinician. Regarding the mild cases of diphtheria with almost no membrane and little or no symptoms, Dr. Sharp said he believed the best plan was to make no more fuss of them than was consistent with ordinary common sense.

Mr. ROBSON showed the following card specimens: 1. A case of Gastrostomy with a small oblique opening. The patient had been fed for eighteen months by means of a catheter through the artificial opening with no tendency to leakage. 2. A case of Pyloroplasty for simple stricture of the pylorus performed five weeks previously. 3. A Calculus weighing 5¾ oz. removed by Supra-pubic Lithotomy.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

The Insanity of Childhood.—Perforating Gastric Ulcer.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Feb. 3rd, Dr. W. B. RANSOM, President, being in the chair.

Mr. EVAN POWELL, in a paper on the Insanity of Childhood, said that the disease was rarely met with unassociated with idiocy or imbecility. The variety and range of the mental disorder varied with the degree of mental development. The insanity of the child was for the most part that of the senses, and the chief characteristics were restlessness, viciousness, and destructiveness. He described a case of mania in a boy aged seven years, who was said to have been frightened by a dog when two years of age, and soon after to have had a sort of "fit"; he showed now and again certain peculiarities of conduct up to the date of the attack of mania; his symptoms were acute excitement, with violence and destructiveness, and there was lack of coördination in the muscles of his limbs and much tremor of the face. A week after admission he had an epileptoid seizure and became unconscious and rigid, but was not convulsed; after this he steadily improved and was discharged after two and a half months' residence. As age advanced the insanity began to simulate that of the adult and delusions and hallucinations appeared, but these were transitory and less liable to become fixed. He (Mr. Powell) related two other interesting cases of acute mania in boys aged fourteen years, the result of injury to the head and epilepsy. The latter, he said, was one of the most common causes of insanity in children. A peculiar feature in some cases he had noticed was the habit of climbing. Occasionally an attack of mania might arise in a congenital imbecile. He related a case in a boy, aged fifteen years, who recovered after an attack of eczema of the scalp. Melancholia in children was rare. Dr. Emminghaus found that out of 199 cases of insanity in children 24 were melancholic. The disease was mostly of the simple variety, but occasionally it assumed the active form, the child becoming acutely distressed, incessantly crying or moaning, and seeming to be in constant terror; delusions of persecution and hallucinations of hearing sometimes were present; but the most striking form in which the melancholia of children manifested itself was by suicide. The suicidal act may be committed under sudden impulse, from the dread of punishment or from disappointment, in some rare instances also from jealousy. He gave some statistics of suicide in children and related a recent case. Moral insanity, another variety of the derangement of the affective faculty, was sometimes met with in children; there was more or less complete perversion of the moral sense, and the child exhibited inordinate vicious propensities, either to steal, to destroy things, to torture animals, or to commit sexual vice. He recommended that such cases should be treated away from home, either under the care of private individuals or in suitable "homes." In conclusion, Mr. Powell related three cases of general paralysis in children aged respectively twelve and a half, thirteen, and fourteen years.

Mr. A. R. ANDERSON read clinical notes of two cases in which he had operated for Perforating Gastric Ulcer. The first patient lived six weeks and succumbed to the results of subphrenic abscess, the site of the ulcer being found firmly healed. The second made an uninterrupted recovery and was shown at the meeting.

The following cases were also exhibited:—

Dr. C. BELL TAYLOR: (1) Bilateral Glioma; (2) Simple Cataract Extraction in a patient aged ninety-six years; and (3) Skin Transplantation for Ectropion.

Mr. STEVENS showed a pathological specimen of a Gastric Ulcer communicating with an hepatic abscess.

KIDDERMINSTER MEDICAL SOCIETY.

Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 29th, the President, Mr. W. MOORE, being in the chair.

Mr. J. L. STRETTON showed:—1. A boy, aged thirteen years, upon whom he had operated for the Radical Cure of Hernia last October; the result was perfect. 2. A man, aged thirty years, who strained himself seven months previously while lifting a heavy weight and ever since had suffered from pain in the left chest and shortness of breath. When first seen about six weeks before there was a systolic murmur heard to the right of the sternum and conducted upwards, but this has disappeared. There was also a marked difference in the volume of the pulses felt at the wrists and they were not synchronous; the difference is still very marked, the left pulse being very thin. There was no specific history, but he was decidedly neurotic. The case was of interest because the question had been raised as to whether his condition was really due to the strain. Mr. Stretton thought that as the result of the accident there was some dilatation of the aorta.—An interesting discussion ensued, some members considering that the symptoms were due to nervous conditions.

Mr. W. HODGSON MOORE showed:—1. A young woman with Specific Disease affecting the bones of the lower extremities. She had derived benefit from large doses of iodide of potassium, but when pushed it did not remove the whole of the disease. He raised the question of whether there was not some other disease in association with the syphilis, but the general opinion of the meeting was against this. 2. A Plaster-of-Paris Jacket which he had removed from a boy who complained of considerable pain in the dorsal region. When removed it was found that a halfpenny had become fixed in the mid-dorsal region and by pressure caused a considerable amount of ulceration. It was then remembered that he had dropped the coin down his back some time before it gave rise to any symptoms.

Mr. E. P. HASLUCK showed a Heart with very extensive Calcareous Degeneration of the Aortic Valves from a man aged seventy-four years. He was only ill for a few hours and died from exhaustion. The degeneration was so extensive that the cusps were rigidly adherent and gave a distinct metallic ring when struck; they felt like rough stones. In spite of this mischief he did not exhibit any serious symptoms, although he had been short of breath for the previous five years. He was walking about, apparently in good health, within a few hours of his death.

Mr. S. STRETTON read a paper entitled Some Notes on the Present and Future General Practitioner.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

The Perigraph.—Dual Brain Action and its Relation to certain Epileptic States.—Operations for Gall-stone.

A MEETING of this society was held on Feb. 3rd, Dr. W. CRAIG, Vice-President, being in the chair.

Dr. GRAHAM BROWN showed an ingenious instrument, invented by himself, which he called a Perigraph, for delineating the shape of the thorax and for clinical mensuration generally. It was based upon the pertagraph, but instead of having a straight arm for following the outline the arm was sickle-shaped and had a joint which enabled it to be turned over so that the point of the sickle could follow a circle.

Dr. LEWIS C. BRUCE (Morningside Asylum) read a paper on Dual Brain Action and its Relation to Certain Epileptic States. He defined the condition as one in which an individual appeared to have two separate states of consciousness and in whom the right and left brains alternately influenced

Hosted by Google

the motor functions. Many cases published as instances of dual brain action were merely examples of delusional states. His attention had been drawn to the condition by a patient in the Derby Borough Asylum who presented two distinct states, which he called the English stage and the Welsh stage. In the English stage he was right-handed, spoke English, but understood Welsh. His memory was a blank for everything that had occurred in the Welsh stage. He wrote with his right hand, but if he used his left hand he wrote mirror-fashion. In the Welsh stage he did not understand English and spoke only in Welsh. He wrote with his left hand and from left to right. Dr. Bruce thought the condition was due to the unequal effects of disease in the two hemispheres and examined the patients in the asylum with a view to elucidating this point, but no case presented the motor peculiarities present in the Welshman. He was led, however, to the study of unilateral epileptic seizures, which suggested that the condition known as epileptic automatism might be due to the seizure paralysing one side of the brain while the other carried on its function. He gave an example of this condition in an epileptic who, after a unilateral fit, was able to walk and feed herself with the left hand. Her mental condition was altered so that when shown money she manifested no desire to obtain it, although in her normal condition she did. The conclusion drawn from this case was that the left hemisphere controlled the right and was more highly educated. After a right-sided seizure the left hemisphere was disorganised and left the other uneducated hemisphere alone acting. He thought it was owing to this that the mental phenomena after a fit were of such a low type. He suggested that in some epileptics the disease was due to a want of equal education in the two hemispheres rendering the patient liable to brain exhaustion under certain conditions.

Dr. RUTHERFORD MORISON (Newcastle-on-Tyne) read notes on cases of Gall-stone. In the first case the gall-bladder was found to be small, but two stones were removed from the common duct. In the second case a tumour could be felt in the right hypochondrium, which descended with respiration and was apparently not a moveable kidney. It proved to be adis tended gall-bladder filled with clear fluid, a single stone blocking the cystic duct. In the third case a tumour, which could be felt in the right hypochondrium in the position of the gall-bladder, was found to be a thin-walled sac continuous with the gall-bladder. The gall-bladder itself was contracted and thickened. Several stones were removed from the sacculus and two from the common duct.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Excision of the Tongue.

A MEETING of this section was held on Jan. 22nd, Professor BENNETT being in the chair.

Mr. WHEELER read a paper on Excision of the Tongue, and referred to sixty-one cases that he had operated upon, stating that each particular case of cancer of the tongue generally required a special operation and that no individual recognised operation would be suitable for every case. He never ligatured the lingual arteries prior to the operation on account of any dread of hæmorrhage during the operation. His practice was to extirpate the tongue before removing the sub-maxillary glands and the enlarged lymphatic glands, as the diseased mass in the mouth was a constant source of irritation and the longer it remained the greater chance there was to the patient of septic poison. He had operated on the tongue with the ordinary scissors, the thermo-cautery scissors, and the electric cautery, and for precision and celerity he thought that, in suitable cases, the thermo-cautery scissors were the best. There was no charring of the part, no sloughing, and no secondary hæmorrhage. He never found it necessary to perform preliminary tracheotomy before excising the tongue, as he considered that there was no compensation to the patient for this additional operation and no advantage to the operator. He emphasised the necessity of absolutely cleansing the mouth and tongue prior to and after the operation. Some of his cases had occurred from three to fifteen years ago and had had no return of the disease. The parts removed were examined by competent pathologists and microscopists and found to be epithelioma.

Mr. SWAN said that Mr. Wheeler was to be congratulated on the fact that he had patients alive fifteen years after operation for this disease, but most surgeons would admit that cases were occasionally seen which presented all the clinical aspects of malignant disease of the tongue—viz., the ragged sore with a hard base, the emaciated appearance of the patient and the enlargement of the neighbouring glands, the age of the patient also being that at which cancer commonly occurred—and which were, however, not cancer but only simulated it and got well under a course of mercury. He agreed with Mr. Wheeler that it was unnecessary to tie the lingual artery as a precaution against hæmorrhage in the removal of the tongue.

Sir THORNLEY STOKER said he did not think that the minute anatomy of the tongue had any essential bearing on the rude facts that they had to deal with in connexion with the surgery of this portion of the body. Syphilis was unquestionably a predisposing cause of cancer, and he also agreed with the remarks of Mr. Swan as to the difficulty of diagnosing many cases of cancer of the tongue from syphilitic affections. Most of them had seen instances of what had commenced as syphilis degenerating into carcinoma. Mr. Wheeler spoke of dividing the gustatory nerve as a means of relieving pain and salivation in cancer of the tongue. He had performed the operation on a good many occasions, and he had not found any marked benefit to result from that proceeding. The gustatory nerve was seldom divided at a time when the nerve was easy of exposure and when the operation was an insignificant one; but when the cancer had infiltrated the floor of the mouth and produced aggravated pains in the ear the division of the gustatory nerve became rather a serious operation. He entirely disapproved of the practice of transfixing the base of the tongue. There was a reason for transfixing the base of the tongue in the days when the écraseur was used in the operation and a needle was put in to prevent it from sliding, but no one would use an écraseur in this operation now. As to the thermo-cautery scissors, he thought it a totally unnecessary instrument. In cases which were proper ones for the performance of the operation, perfect command over the vessels was obtained by performing Whitehead's operation and using a clipped forceps if an artery began to bleed. He had never found it necessary to divide the cheek, and dividing the lower jaw and opening the floor of the mouth were, in his opinion, unnecessary practices. Complete access could be got to the base of the tongue—in spite even of the small mouths that Mr. Wheeler seemed to have found so common—through the oral aperture by Whitehead's operation, and as far back as it was safe for the surgeon to carry that operation. He had of late years done no operation except Whitehead's, and he believed it to be the best for removing the tongue in a case of cancer. In the last case he operated on he found it necessary to go so far back that he had to remove the anterior artery of the palate and a portion of the tonsil on one side, and he found no difficulty in doing it by Whitehead's operation. The tongue could—by a pair of forceps, and not by the old practice of a ligature—be drawn so far out of the mouth that the operation was practically an extra-buccal one; and every artery that sprang—there were only four or five—could be secured by a clipped forceps and tied. He believed that the practice of operating in hopeless cases of cancer of the tongue was a bad one. In ordinary cases deligation of the lingual arteries was unnecessary.

Mr. TOBIN said that in cancer of the tongue he should like to see an operation of such magnitude undertaken that not only would the diseased tongue be removed—not through the mouth, but through an incision underneath the jaw so that the floor of the mouth and all the structures in their continuity could be reached as far as possible—but also the glands connected with it.

Mr. M'ARDLE said that where the disease had not returned for fifteen years it would be very desirable to have a microscopic section which would indicate the character of the disease at the outset. His experience in cases in which the diagnosis had been thoroughly established was that the return took place very much earlier. The phrase "removal of the tongue" was hardly sufficient for nineteenth-century surgery. It was not sufficiently definite. Removals of the whole tongue, of a patch at the side of it, and of the front of it should be distinguished. If statistics were to be of any use they should be founded on something definite. A cancer engaging the base, or one side of the tongue, bore little or no resemblance to a cancer

Hosted by Google

on the tip of it, and these degrees of affection should not be all classified in a heap. He was adverse to the practice of charring the mouth by cautery. The operator saw nothing of what he was doing; he never knew whether he had got beyond the limits of the disease or not, and though the practice in question was the readiest way it was not the most perfect. If the disease had engaged the base of the tongue the lingual artery should be secured and a submaxillary incision should be made outside the mouth, for once the base of the tongue had been infiltrated with cancer the sub-lingual glands must be infected, and it would be impossible to remove them without an external incision.

Mr. LENTAIGNE said that up to two or three years ago they firmly believed in Whitehead's operation; but they did not get to the root of the disease by it, and if there were an extension of the disease to the glands Whitehead's operation was not sufficient. If he were tempted by a very small cancer at the end of the tongue to perform Whitehead's operation, he would go on to a second operation and search for the glands, especially under the upper portion of the sterno-mastoid, where, in his experience, recurrence most often took place. He agreed with Mr. Wheeler as to the importance of having the mouth clean before the operation. Cautery of any kind was objectionable. He had frequently used adhesive gauze after operations on the tongue, and had found it to be of great use. It protected the cut surface from food, &c., and the healing proceeded in a most satisfactory way under it.

Mr. DOYLE said that the thorough removal of cancer of the tongue and all the glands and the diagnosis of this disease were by no means easy. A late associate of that society, who had a small white spot near the margin of the tongue, was seen when it first appeared by specialists in London and other cities, who said there was nothing in it. Three years afterwards it was removed by an operation under cocaine. The removed portion was submitted for microscopic observation to another specialist, who could not tell anything about it. Three months afterwards the disease recurred in the submaxillary glands and terminated fatally.

Mr. MYLES said that quite recently, with the assistance of Sir Thornley Stoker, he operated on a supposed cancerous tumour of the breast, and as the question of diagnosis was very doubtful he called in a younger colleague, Mr. Greer, who was an experienced microscopist, and made a microscopic examination of part of the tumour, but the result was nil. Microscopic examinations of scrapings or of fresh sections of the tongue were absolutely unreliable. Professor Hamilton of Aberdeen brought under the notice of the profession the changes that occurred in the tongues of old people, and produced microscopic sections of the tongues of persons over fifty-five years of age, and every one of these presented the identical appearances that were usually associated with epithelioma. He placed side by side with them sections of clinical epithelioma and the most expert pathologists were unable to distinguish between the two. When he (Mr. Myles) was house surgeon of Steevens' Hospital a case came there to be operated on for cancer of the tongue, and everybody, except Mr. Edward Hamilton, diagnosed it to be epithelioma. The patient was a woman of sixty-five or sixty-six years of age, who was the mother of eighteen children and the grandmother of twenty-four. Mr. Hamilton suggested a mild course of mercury, which was adopted, and she went home perfectly well. In a large percentage of cases it was impossible to distinguish a syphilitic gumma from true epithelioma.

Mr. WHEELER, in reply, said that he had recorded the history of his cases as fully as he could. There were only ten that he could account for. In twenty-nine he knew that the disease returned. As to twenty-two, he had no direct knowledge of the disease not having returned, but he heard indirectly that five of them were alive.

THE SOUTHAMPTON WATER SUPPLY.—The Directors of the South Hants Waterworks Company, whose undertaking the Southampton Corporation is endeavouring to compulsorily acquire, announce in their half-yearly report that they are taking steps to oppose the Bill by every means in their power, feeling assured that by so doing they are protecting the best interests of the proprietors. It is of interest to note that they report last year an addition of 994 houses to the rent-roll, giving an increased annual rental of £1,222. They declare dividends for the half year of 10 and 7 per cent.

Reviews and Notices of Books.

Handbuch der Gynäkologie. In drei Bänden. Herausgegeben von J. VEIT (Leyden). Mit zahlreichen Abbildungen. Erster Band. Wiesbaden: Verlag von J. F. Bergmann. (*Handbook of Gynæcology.* In Three Volumes. Edited by J. VEIT (Leyden). With numerous Illustrations. First Volume. Wiesbaden: J. F. Bergmann.) 1897. Pp. 628.

THE volume before us is the first of three about to be edited by Dr. J. Veit, the complete work promising to be an important contribution to gynæcological literature. It contains five monographs by well-known and able men, who present to the reader the results of the latest observations. The subjects taken in order that are here discussed are: Asepsis and Antisepsis in Gynæcology, by Dr. H. Löhlein of Giessen; the Anomalies of Position and of Movement of the Uterus and Neighbouring Organs, by Dr. Otto Küstner of Breslau; the Diseases of the Vagina, by the editor, Dr. J. Veit of Leyden; Gonorrhœa, as it affects the Female Genito-Urinary Organs, by Dr. E. Bumm of Basel; and the Development and Defects of Development of the Female Generative Organs, by Dr. W. Nagel of Berlin.

Dr. Löhlein, in his article on Asepsis, shows himself to be a staunch adherent of the doctrines advocated by Lord Lister. Cleanliness in the gynæcologist should be a reflex act. He discusses the merits of various antiseptics that have been found serviceable, amongst which may be mentioned lysol, kresol, creolin, solveol, aqua chlorata, lime chloride, and others. For purification of the hands, sand and soft soap may be used with advantage. Woodcuts are given showing the construction of various sterilisers. For the purification of catgut he recommends cumol, the high boiling point of which, from 160° to 170° C., destroys some form of germs that remain capable of proliferation in boiling xylol the boiling temperature of which does not exceed 136° to 140° C. Silk is more easily purified. Full instructions are given in regard to the arrangements of the operating theatre and of the perfect cleansing and sterilisation of instruments and for the preparation of the patient when vaginal and other operations, such as laparotomy, have to be performed. A table is given showing the excellent results obtained in the Giessen Hospital for Women since the introduction of asepsis, only 4 per cent. dying under the most serious operations. The article which will, perhaps, be perused with most interest by those who can read German is that of Professor Otto Küstner of Breslau, the contents of which we may briefly indicate. After a short section devoted to the normal position and movements of the uterus he passes on to the consideration of pathological fixation the result of parametritis, and then discusses abnormal mobility, with anteflexion, retroflexion, lateral flexion, torsion, prolapse, inversion, eversion, and hernia, with the special methods of relief devised or practised by the author, and a very large number of excellently drawn illustrations. Moreover, each of these sections is preceded by an excellent bibliography.

Dr. Veit, in his article on the Diseases of the Vagina, gives an excellent account of modern bacteriological investigation in regard to the micro-organisms present in the vagina. Various observers, he points out, have shown that organisms are present normally which might easily, under appropriate conditions, induce puerperal fever and death, and that such auto infection does actually occur in even well-appointed institutions. The reason why this does not occur more frequently is, according to Döderlein, that the vaginal mucus has a strongly acid reaction, and is therefore an unfavourable medium for the growth of micro-organisms, whilst in disease the secretion may become neutral or even alkaline. The bacilli in health are few in number and of definite

Hosted by Google

nature, whilst in disease they present great variety, and, amongst them doubtless there are some saprophytes and pathogenic germs. Much doubt, however, seems to exist in regard to the whole of this inquiry, and much more investigation is evidently required before any positive statements can be made, the researches of Krönig, for example, being by no means in accordance with those of Döderlein. Dr. Veit describes with much interesting detail inflammation, wounds, and foreign bodies in the vagina, neoplastic formations, (such as cysts, myoma and sarcoma, malposition, and, finally, fistulæ) communicating with the large and also with the small intestines. The treatment of such cases will, we presume, be given in detail in some future article, as it is here only glanced at.

Dr. Bumm, to whom with Neisser and Haab science is indebted for the demonstration of the micro-organism constantly associated with gonorrhœa, treats the subject which he has made his own in a very satisfactory manner. He remarks that, considering Dr. Bernutz and Dr. Goupil as long ago as 1857 drew special attention to the extension of gonorrhœal inflammation to the Fallopian tubes and the frequency of pelvic peritonitis in connexion with it, he has been greatly surprised that it was very generally overlooked n works published twenty or thirty years later. It required the monograph of Noeggerath to compel the attention of practitioners to the serious effects of gonorrhœa in the female, and it needed experimental and microscopic evidence to establish the facts that are now generally admitted. A similar uncertainty existed in regard to purulent ophthalmia, and it was reserved for Zweifel in 1884 to supply evidence by inoculation that ordinary lochial secretion is incapable of producing blennorrhœa. Dr. Bumm gives an exact description of the gonococcus, the size of which he estimates at 1·2 μ from pole to pole. It is, he says, the micro-organism of all those at present known—at least, of those that are pathogenic in man—which has attained the highest grade of parasitic adaptation. Whilst other pathogenic germs, such as the bacteria of tuberculosis, of splenic fever, and of typhus fever, can thrive well in the bodies of animals, the gonococcus attaches itself exclusively to the human mucous membrane. All attempts to infect the lower animals with it, even the highest apes, have signally failed. That the gonococcus is the active agent he considers to be demonstrated by the fact that severe gonorrhœa can be caused by inoculation with the pure culture twenty removes from the original matter, and a slighter attack even after thirty pure cultures in succession. Dr. Bumm has examined fragments of the cervical mucous membrane in cases of recent infection and finds that the gonococci penetrate as far as the connective tissue of the mucosa between the epithelial cells, these last, being detached, either leaving the surface denuded or being replaced by flattened or roundish cells. He has carefully examined the membrane of the uterus in five cases in which the uterus was removed on account of chronic salpingitis. The infection was found invariably to be limited to the mucous membrane, the muscular tissue being quite free from infection. The glands of the cervical region were invariably intact. The cells covering the papillæ are often very healthy. The gonococci have to be searched for sometimes over areas of considerable extent. Hence he arrives at the conclusion that in chronic cervical gonorrhœa the invasion of gonococci is limited to a few isolated and very small patches of the membrane. He gives drawings which bear out his statement.

From the present standpoint of our knowledge Dr. Bumm is inclined to think that recovery from an attack of gonorrhœa must be due to functional changes in the protoplasm of the regenerated epithelial cells rendering the cells capable of resisting the inroads of the gonococci. This immunity, however, only exists for the particular attack, and so long as the gonococcus is present in the secretion, since a new germ or germs can easily induce another inflammatory outburst. Gonorrhœal inflammation of the urethra occurs with great frequency in females, as all those who have to deal with lock hospitals for females know, but is in general easily cured. The microscopical characters are similar to those in men. The extension of the inflammation to the bladder, ureters, and pelvis of the kidney is rare. Gonorrhœa extending to the interior of the uterus and even to the tubes is not uncommon, and of the inflammatory appearances and of the invasion of the micrococcus in both of these parts and of the ovaries, peritoneum, and rectum Dr. Bumm gives minute and carefully written accounts. From his own and recorded observations he shows that gonorrhœa though a frequent, is not by any means a constant cause of sterility. He gives some statistics of the frequency of gonorrhœa in New York on the authority of Noeggerath—statistics that must, we think, exaggerate the prevalence of the disease, although, no doubt, it is common in all large towns. Whilst many pages are devoted to the diagnosis and symptomatology of gonorrhœa there is but a small space occupied with the treatment, and the changes must still be rung on perchloride of mercury, nitrate of silver, and carbolic acid injections, and other well-known measures. If the successive volumes of this work are maintained at the same high level as this, the work will prove of the greatest value to the practitioner.

Essays and Addresses. By Sir JOHN RUSSELL REYNOLDS, Bart., F.R.S., M.D. Lond., LL.D. Aberd., LL.D. Edin., late President of the Royal College of Physicians of London and of the British Medical Association; Physician to Her Majesty's Household; and Consulting Physician to University College Hospital. With Portrait and brief Biographical Sketch. London: Macmillan and Co., Limited. 1896. 12*s.* net.

WE have rarely, if ever, read a volume with greater pleasure than this, and in publishing it Lady Reynolds should earn the gratitude not only of the medical profession, but of all, whatever their rank or calling, who love noble thoughts nobly expressed. The papers of which it is composed were personally selected with others for publication by the late President of the Royal College of Physicians of London, and it was his intention to write appendices to them where it appeared to him that such additions were required to bring the matter up to date. The experience of half a century's assiduous practice in hospital ward and consulting-room was at his disposal to be drawn upon, and leisure alone was wanting for the completion of the task in accordance with his wishes. But this leisure never came. "My husband died," says Lady Reynolds, in her graceful and pathetic little prefatory note, "when the work was merely planned in his mind. I have, therefore, chosen from among the selected papers some of general interest, the majority of which would have been published by Sir Russell Reynolds without alteration Here, we think, Lady Reynolds adopted a wise course. There were many papers left behind him by Sir Russell Reynolds that might well have been re-published—the Lumleian Lectures, for example, upon the Relation of Medical to Legal Practice; but it was their author's opinion that they required alteration or explanatory notes to give them their complete modern value. Either, then, the work would have to be published in a form with which Sir Russell Reynolds had expressed himself as not quite satisfied or it would have to be entrusted to another hand to write the additional notes. Neither course would have been absolutely satisfactory, and we consider that it was a wise decision to give to the public only such work as had, firstly, passed the test of the author's hardly-earned approval and, secondly, such as called for no elucidation or editorial addition from

Hosted by Google

the pen of another. For in this way we have obtained not only a volume of fine and finished essays, each complete in itself and carrying its distinct and unmistakeable message, but we have also obtained a very faithful portrait of the author's mind.

In the first essay in this book, entitled "The Relation of Practical Medicine to Philosophical Method and Public Opinion" we have very clearly displayed the fact that Sir Russell Reynolds estimated other qualities in the physician as much as technical skill, and this fact forms a sort of key-note of all the other essays. Proper scientific equipment the student of medicine must have, but psychological knowledge he must also possess, and he cannot obtain this by intuition. Powers of observation must be trained as groups of muscles are worked up to perfected movement by the athlete; and the habit of logical thought must be as much fostered and instructed as the habit of daily exercise if the result is to be the alert mind comparable to the alert body. But Sir Russell Reynolds's Aristotelian teaching does not stop here. The true student of medicine—we do not use the term student as meaning a school-boy or an examinee, but as implying all who are wishful to learn—should not hold that he has complied with all possible requirements when, in addition to practical and text-book knowledge of his particular science, he has mastered the forms for the analysis of reasoning, and assumed the habit of putting these forms to practical employment in his work. In every science or branch of knowledge facts must be studied; in every science or branch of knowledge these facts must be arranged and must be weighed and their conclusions must be looked to as much as the premisses upon which they rest. But in the science of medicine, at any rate, this is not all. In the science of medicine sympathy, charity, and imagination play a part that they do not play in more exact sciences. While Sir Russell Reynolds in some essays—as for example in the address at the opening of the Westminster Hospital Medical School in 1859, entitled "The Facts and Laws of Life," and in the introduction to the System of Medicine—lays particular stress upon the value of logic, he is careful in others to point out that nature cannot be expounded by syllogisms and that the medical man wants hope, love, and belief in an ordained scheme for good, as well as his technical knowledge and his orderly mind, if his services are to be, what he should strive to make them, for the good of his generation. To the teacher of such doctrines, it need hardly be said, the transcendental side of medicine would naturally appeal, and some of Sir Russell Reynolds's finest writing—an address on the Present Position of Medical Knowledge, delivered at Norwich in 1874, and certain passages in the Harveian Oration of ten years later, for example—are devoted to showing how all embracing is the science which deals with life as approached from the avenues of disease, and how necessary it is that the votaries of such a science should be single-minded in their intent to search out the truth, yet humble-hearted in their conviction that the test-tube does not contain the whole story of the creation. The true physician, according to Sir Russell Reynolds, must be the true philosopher or lover of wisdom. Where a defined range of accurate performance is possible he cannot be too accurate, but before the unknowable he must be neither impertinent nor despairing. To see in a glass darkly is not a performance to be ashamed of. It is better than entire inability to see. The wise man will understand his limitations and work on strenuously and humbly that he may set back those limitations if not for himself at least for generations that are to come. To accept what cannot be explained is not a sign of confessed credulity, and the most learned man is the man that has learned to look upon his knowledge as so infinitely small compared with the magnitude of the things that remain to be known, that it is borne in upon him that even he is ignorant. This is but a bald exposition of Sir Russell Reynolds's attitude towards the greatest problems of our cosmogony, and we recommend our readers to study "The Relation of Practical Medicine to Philosophical Method and Popular Opinion," written in 1858; "The Present Position of our Knowledge," which was the address in medicine delivered before the British Medical Association in 1874; and, lastly, the "Organised Progress of Medicine," the Presidential address to the same body twenty-one years later. They will in those papers see Sir Russell Reynolds's faith revealed.

From this high philosophical level of thought several of the essays make a gentle descent and reveal the author in the more familiar mood of practical adviser, discoursing humourously of things as they are and things as they ought to be in the medical career. To this category belong the well known introductory lecture entitled "Types of Students," delivered to the Medical School of University College in 1863 and reprinted in THE LANCET as recently as 1894; the essay entitled "Specialism in Medicine," a speech before the Medical Society of University College, London, in 1881, and the paper on the Value of Competition, an address delivered on prize-day, 1885, at University College, Bristol. The first of these essays is the most broadly humorous, the second is the most caustic, and the third the most directly practical. But all three serve to show their author in a totally different aspect from that in which he presents himself to us in the more stately compositions to which we have already alluded. There he is an instructor whose ideals are hard to follow and whose optimism may appear not altogether justified by the affairs of everyday life, because based upon a range of knowledge with which the everyday working man is not dowered. Here he is the shrewd and genial adviser, familiar with the troubles, pitfalls, and temptations that assail the men of his own calling from their entry as students until the end of their professional careers, and as prompt to put a finger upon the sore spots as to recommend remedies of a thorough and drastic sort.

We have resisted many temptations in the course of this review to quote copiously from the pages. The essays abound with phrases which form remarkable illustrations of the bent of the author's mind and of his high and sensitive moral standard, but they are composed with such regard for symmetry and proportion that detached passages, however pregnant of meaning, brilliant, or humorous, do not give a fair idea of the whole. It is as a whole that we recommend their perusal to our readers. Their teaching is noble; their wisdom is deep and shrewd; frequently they move to laughter, and now and again they may provoke tears. No one can rise from reading them without feeling that they have held intimate communion with a man whose sympathy was as broad as his penetration was acute and whose wide range of learning and career of unbroken worldly success only served to make him the kinder critic of less gifted men and the readier friend of less fortunate.

Hygiene for Beginners. By ERNEST SEPTIMUS REYNOLDS M.D., F.R.C.P. Lond. London: Macmillan and Co. 1896 Pp. 226. Price 2*s.* 6*d.*

THIS is a small but, so far as it goes, a very excellent little book. It is an expansion, as the author tells us in his preface, of a Primer of Hygiene written by him in 1894 for the use of higher-grade school children and the like. As an introduction to the chapter upon Hygiene a short but succinct account of anatomy and physiology has been added. These two subjects, though necessarily treated in a very cursory manner, are set out with lucidity. Part II., which is concerned with hygiene, commences with a short history of hygiene, and mentions various pioneers in the field of

Hosted by Google

sanitary science and preventive medicine, such as Cook, Howard, and Jenner. The author is wrong, however, in saying that "Cook first showed how to prevent scurvy on board ship" (p. 106). That honour belongs to James Lind, physician to Haslar Hospital, who published his treatise on Scurvy in 1753, while Cook published, or rather read, his paper before the Royal Society in 1775.

There is an excellent chapter on Parasites and their Action on the Body, which includes a short account of bacteria.

Other chapters deal with Impurities in Air and in Water and the diseases they cause; and with Food, Cooking, and Beverages. We cannot agree with Dr. Reynolds in thinking that three-year-old mutton is the best. Five-year-old is far superior. On page 139 salt is included among the condiments as "not in any sense a true food." This is obviously a slip which should be corrected in the next edition, for on pp. 91 and 134 salts are given as necessary parts of the perfect diet.

The chapters on Ventilation, Warming, Lighting, and the Dwelling-house in general are well and clearly written, but in that upon Personal Health, although ordinary baths are spoken of, there is no mention of the Turkish bath, that invaluable adjunct to health, especially for the town-dweller. The chapter upon infectious diseases is admirable, except, we fancy, that Dr. Reynolds makes too light of German measles. The book ends with a clearly-written chapter upon what to do in various medical and surgical emergencies. Altogether this is an excellent little book, despite the one or two slips which we have pointed out, and one we can recommend to parents, guardians, schoolmasters, and others.

A Manual of Infectious Diseases. By E. W. GOODALL, M.D Lond., Medical Superintendent of the Eastern Hospital of the Metropolitan Asylums Board, formerly Medical Registrar to Guy's Hospital; and J. W. WASHBOURN, M.D., F.R.C.P. Lond., Physician to the London Fever Hospital, Assistant Physician to Guy's Hospital and Lecturer in the Medical School. London: H. K. Lewis. 1896. Pp. 368. Price 15*s*.

THE authors have produced an excellent and well-balanced handbook. Facts are clearly stated, and no recent results of any value omitted. The five opening chapters on Fever, Contagion and Infection, Disinfection, Rashes simulating those of the Specific Fevers, and Sore-throat give precisely what a student needs. Controversy is, as far as possible, kept in the background, and the heated discussions on cow scarlet fever of a few years ago are here summed up as follows: "In others [milk-supplies] no such infection could be traced, even after the most careful investigation, but the cows supplying the milk were found to be suffering from a disease of the udder, skin, and viscera; and it has been supposed that this was really scarlet fever in a modified form." The account of the complications of scarlet fever and their treatment is very good and full. In a future edition, in describing the distribution of diphtheria, it might be well to enter into a little more detail. The curious facts brought out in Dr. Longstaff's paper and map are worthy of much attention, and every medical man would be capable of adding to our knowledge of them if the lines of inquiry were pointed out. The bacteriological examination of diphtheritic membrane and the differences between various forms of bacilli found are clearly explained. There is also a very lucid account of the standardising of antitoxic serum. In the chapter on Small-pox and Vaccination there is nothing new, but all necessary points are well brought out. The chapter on Enteric Fever is detailed and practical. The book is a thoroughly sound one.

LIBRARY TABLE.

Transactions of the American Gynæcological Society. Vol. XX. Philadelphia: Wm. J. Dornan, Printer.—There are several papers of interest in this volume. We may especially mention one by Dr. S. C. Gordon, entitled "Further Experience and Observations in Hysterectomy for Fibroids." He believes that hysterectomy for fibroids of the uterus should be as much the general rule as ovariotomy for tumours of the ovary. His last twenty hysterectomies for fibroids have been without any mortality. Another paper of interest is by Dr. Howard Kelly on the Renal Catheter and its Uses in the Diagnosis and Treatment of Renal Diseases. He passes the catheter into the ureter through a speculum, and this method, which appears to be especially dependent on a good light being available, seems far better than any attempt to pass a catheter into the ureter by the sense of touch alone. There is also an exhaustive paper on Deciduoma Malignum, with numerous references, that will prove of great use to anyone desirous of looking up this subject. The volume is quite equal to any of its predecessors, and it contains a general index of Volumes I.—XX.

JOURNALS AND REVIEWS.

Scottish Medical and Surgical Journal.—Professor McCall Anderson (Glasgow) describes a case in which hæmatoporphyrin occurred in the urine in connexion with attacks of hydroa æstivale. The patient was a man, twenty-six years of age, who had from infancy suffered annually from an eruption of the face, ears, and hands. It usually began in early summer and disappeared on the approach of winter. The first symptom was a sensation of itching and burning, which after ten or twelve hours was followed by the formation of blisters filled with a greenish serum. The urine was acid, and contained no albumin, sugar, bile pigment, or blood, but was of a light burgundy-red colour, which spectroscopically seemed to be identical with alkaline hæmatoporphyrin. Professor Annandale (Edinburgh) contributes two cases of strangulated obturator hernia, one case of suppurating dermoid cyst of the ovary simulating suppurative appendicitis, and three cases of intestinal obstruction from fæcal accumulation. Dr. P. Blaikie Smith (Aberdeen) gives an account of two cases of tumour of the brain. Dr. Elder (Leith) publishes the first portion of a paper on Agraphia and the Existence of a Special Graphic Centre.

St. Bartholomew's Hospital Journal.—In the January number Dr. Edmund Cautley discusses the therapeutic value of food in infantile diarrhœa. He concludes with the following remarks:—"Let me advise you to treat every case on its merits, and not to stick to any hard and fast rules, and apply such rules to rich and poor, to the well-nourished and the marasmic, to the intelligent and the stupid, in the heat of a tropical climate and the cold of more northern regions. Bear in mind that almost all cases are due to errors in diet, and that on a suitable food the patient will rapidly recover. With care and patience investigate every case, and think no detail too trivial for even the greatest among us, if it leads to the recovery of a single life or the relief of a single symptom." Dr. Kanthack continues his Pathology Jottings and Mr. Alban Doran contributes a paper on the Details of Ovariotomy and Disputed Points in After Treatment.

The Middlesex Hospital Journal.—The Middlesex Hospital has determined not to be behind some of the other large metropolitan schools in possessing a journal of its own, and accordingly the first number, which is published by Messrs. Mitchell and Hughes, 140, Wardour-street, W., price 1*s*., has just been issued. The editor hopes that as "'Middlesex' men are to be found in every direction, ... our journal will .....

Hosted by Google

form a connecting link between them all." The journal is intended for students as well as for past pupils of the hospital, and the objects of the new venture comprise the record of events of interest in connexion with the hospital and school, together with lectures, addresses, and clinical notes. The first number contains an excellent reproduction of a photograph of the late Mr. J. Whitaker Hulke, F.R.S., and among the literary matter we find a clinical lecture on Two Cases of Stone in the Bladder by Mr. Henry Morris, F.R.C.S. Eng., and a note on the Condition of the Knee-jerks in Fracture-Dislocation of the Spine by Dr. Campbell Thomson. We congratulate the editor on the "get up" of the first number and wish the new venture every success.

St. Mary's Hospital Gazette. The first number of Vol. III. is embellished with a portrait of Surgeon-Lieutenant-Colonel A. T. Norton, V.D., whose career is also briefly sketched. Surgeon-Lieutenant-Colonel Norton, who is the popular commander of the Volunteer Medical Staff Corps (London companies), is also an old pupil and late member of the staff of St. Mary's Hospital, and has just been elected consulting surgeon to that institution. Among the Editor's Notes we observe an announcement that a new post of medical officer for the selection of out-patients has been constituted. "The holder of this office, who must be a Member of the Royal College of Physicians, will attend the out-patient department daily and see all the new medical out-patients, and select each day not more than twenty-five cases of the greatest severity and transfer them to the physician to the out-patients, himself dealing with the remainder according to prescribed directions." By this arrangement it is hoped that benefit will accrue both to patients and students. Would it not be possible for the new medical officer while making his selection of suitable cases from a medical point of view to give an eye to each case with regard to the worthiness on the part of the patients to receive free treatment?

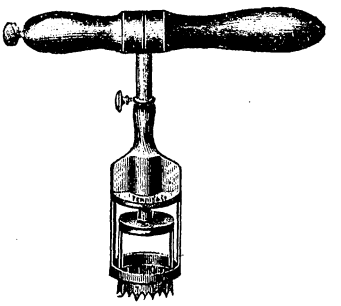
Knowledge.—This month the contribution to the series of articles on the Science of the Queen's Reign is from the pen of Miss Agnes M. Clerke, and deals briefly and in a popular way with the progress of astronomical research during the past sixty years. Under the heading A Pantheon of Science Mr. John Mills gives a summary of the history of the Royal Institution. It is some 100 years ago since that temple of science was first conceived by Benjamin Thomson, and the recent opening of the Davy-Faraday Laboratory, besides marking an epoch in the history of applied science in this country, forms a fitting memorial of the centenary of the Royal Institution of Great Britain.

The Cornhill Magazine.—There is a certain class of patients who are never satisfied unless their medical adviser "gives them something." To physicians who deal with such we recommend a perusal of an article by E. H. Parker upon Diet and Medicine in China. Imagine the effect upon a nervous patient of seeing "toads' eyebrows" in a prescription. E. T. Murray Smith has an interesting article upon Two Centuries of National Monuments in Westminster Abbey. The eighteenth century, although it produced furniture, jewellery, miniatures, fabrics, porcelain, plate, bindings, and music all of the highest quality, was sunk in the lowest depths as regards anything ecclesiastical. Hence the paganism and hideousness of the monuments of the time. And the epitaphs! Here is a portion of one upon Admiral Vernon:

> "Dying he bid Britannia's thunder roar,
> And Spain still felt him when he breathed no more."

This is as good as—

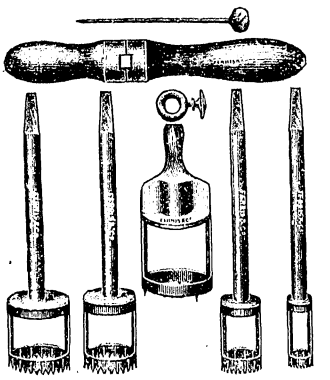
> "Fancy six hundred gentlemen at least,
> And each man mounted on a capering beast."



Some nineteenth century memorials are not in the highest art, witness the Stephenson window with the mud-dredger, but they are not so pretentious as their predecessors.

New Inventions.

NEW TREPHINE.



ON several occasions on which I have had to trephine for compound depressed fracture of the skull it has occurred to me that it would be an advantage to have an instrument without the central pivot pin and one which could, therefore, completely encircle the depressed bone. With the old instrument, the pin having to be placed upon the edge of the underpressed part of the skull, obviously necessitates having to remove an unnecessarily large portion of sound bone and

FIG. 1.

often the trephine cannot completely cover the fracture. Messrs. Ferris and Co. of Bristol at my suggestion have made an instrument which consists of a circular guard with three projecting points surrounding the saw edge, so as to get a purchase on the sound bone until a sufficiently deep groove has been cut. The guard can be held with the left hand while the right hand rotates the saw, and the guard can be made adjustable so as to regulate the depth of the saw cut. Trephines of various sizes can be adjusted to the same

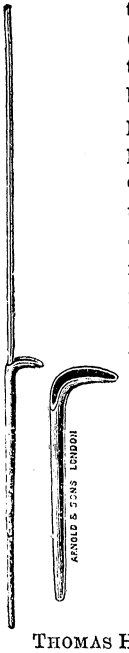
FIG. 2

handle and only one guard is required. This instrument not only meets the particular object I had in view, but has also other advantages over the old-pattern trephine. The blade being open, it is light and the operator can see what he is doing. The stop collar on the stem regulates the depth of the saw cut. The whole instrument can be taken apart for cleansing and sterilising without any trouble.

WALTER FALLA, M.R.C.S. Eng., L.R.C.P. Lond.,
Surgeon to the Jersey General Hospital.

A THROAT IRRIGATOR.

I WISH to call attention to a simple and effective throat irrigator which has been manufactured by Messrs. Maw, Son, and Thompson from a design of Miss S. Copeman, a district nurse. The fluid to be used is contained in a pear-shaped india-rubber ball of three or four ounces capacity, to which is screwed a metallic tube about five inches long, curved at right angles in the middle. This tube is about the size of a



Hosted by Google

No. 12 catheter, and at its further extremity it carries the nozzle, of which there are two forms, one flat-ended and the other spherical, both of them being pierced with very numerous minute perforations. The irrigator has been used in a large number of cases of diphtheria and scarlet fever in the Croydon Borough Hospital, and has proved easy to manipulate, leaves one hand free for the use of a tongue depressor, and does not give rise to the apprehension occasioned to nervous children by the hissing sound of some forms of apparatus.

LEONARD WILDE, M.D. Durh., M.R.C.P. Lond.
Palace-chambers, Westminster.

A MODIFIED NASAL STYLE AND PROBE FOR RADICAL CURE OF NASAL DUCT OBSTRUCTION.

THE advantages of this probe are:—1. The introduction of the style is facilitated by use of the probe. (*a*) The probe may be passed first and the style then threaded over it, the horizontal limb being convenient to lay hold of. (*b*) The probe may be placed in the style—its end just projecting through—thus converting an open end with sharp margins likely to hitch against the mucous membrane of the tube or any obstruction into a solid point which will more readily pass any stricture of the duct. 2. When *in situ* the style can be worn indefinitely, for (*a*) being hollow it allows the tears to pass down and the obstruction is at once relieved; and (*b*) the horizontal limb of the style lies in the slit inferior canaliculus, where it is not visible. 3. The open elbow of the style is less liable to blockage by mucus and is more easily cleansed while *in situ*, as when blocked it is only necessary to pass the probe down in order to ensure patency. These styles have been made for me by Messrs. Arnold and Sons, London.

THOMAS H. BICKERTON, M.R.C.S Eng., L.R.C.P.Edin.
Liverpool.

THE DILATING URETHRAL BOUGIE referred to in our issue of Feb. 6th, under the heading of "New Inventions," may be obtained from Messrs. Down Bros., St. Thomas-street, Borough, S.E.

LONDON LOCAL DEATH-RATES.

IT has been asserted on good grounds that London is the healthiest large city in the world. The Registrar-General's annual summary for 1895 gave mortality statistics for three European and three American cities having populations exceeding 1,000,000, in addition to those for London. These cities were Paris, Berlin, Vienna, New York, Brooklyn, and Philadelphia. The death-rates in these six foreign cities and London ranged from 19·4 and 19·8 in Berlin and London to 23·1 and 23·3 in Vienna and New York. It would thus appear that in 1895 the Berlin rate was slightly lower than the London rate, whereas the rate in each of the other five cities exceeded the London rate. As regards the Berlin mortality it should be pointed out that the low birth-rate suggests an over-estimate of the population, in which case the death-rate would be understated.

During last year the London death-rate further fell to 18·2 per 1000, which in an urban aggregation of nearly 4,500,000 persons, a large proportion of whom are living, as Mr. Charles Booth tells us, under absolutely poverty-stricken conditions, is a result of which the metropolitan sanitary authorities may well be proud. A careful analysis, however, of strictly local statistics abundantly proves how much still remains to be done before the possible minimum town death-rate is obtained, even in London. Dr. T. Orme Dudfield has recently issued an Annual Summary of Vital Statistics for Kensington, for which sanitary area he has long held the office of medical officer of health. His statistics are based upon the results of the London Quinquennial Census in March last, and thus acquire additional value. On this basis Dr. Dudfield estimates the population of Kensington in the middle of last year at 170,000 persons, among whom the birth-rate is stated to have been only 30·2 in 1896, to which it has steadily declined from 33·1 in 1868. Dr. Dudfield, with a view to ascertain the health-condition of various parts of his district, which vary widely in many respects and especially in the social status of the inhabitants, has divided Kensington into six sanitary districts, in which the birth-rate last year ranged from 11·4 in the south-east to 32·1 in the north. In three of these sanitary districts the birth-rate was below 16 per 1000, showing the abnormal constitution of their population, which probably includes a very high proportion of domestic servants, who practically contribute locally neither to the birth-rate nor to the death-rate. The variations in the death-rates in Dr. Dudfield's sanitary subdivisions of Kensington are fully as wide as those in the birth-rates. The death-rate in the whole of Kensington was equal to 16·7 per 1000, and was almost identical with the mean-rate in the ten preceding years. In the south-east and south-west sanitary districts the death-rate in 1896 was so low as 9·1 and 13·4 per 1000, while it ranged upwards in the others to 20·0 in the north and 30·9 in the north-west. Thus Kensington includes an area with a population of 21,040 persons, among whom the death-rate last year was practically double the rate that prevailed in the remainder of the district. Dr. Dudfield further points out that in the "Notting Dale" special area, with a population of 3740, which forms part of this insanitary north-west sanitary district, the death-rate last year reached the startling figure of 50·0 per 1000. Whether tested by the crude death-rate at all ages, or by the zymotic death-rate, or by the rate of infant mortality, this north-west sanitary district affords conclusive evidence of unsatisfactory health-condition. The death-rate from the principal zymotic diseases in Kensington was last year 2·7 per 1000 against 3·2 in the whole of London. In the six sanitary districts it ranged from 1·2 in the south-east and south-west, to 5·9 in the north-west, while in the "Notting Dale" area it was no less than 8·0 per 1000. Kensington, notwithstanding its very low death-rate at all ages, showed last year a rate of infant mortality of 178 per 1000, exceeding the mean rate in London by no less than 18 per 1000. In the sanitary districts this rate of infant mortality ranged from 109 in the south-east, to 281 in the north-west and in the "Notting Dale" special area the appalling rate of infant mortality was 432 per 1000, signifying that very nearly half the children born died before completing their first year of life. These important figures, showing strictly local death-rates within the district of Kensington, have been prepared by Dr. Dudfield in response to a request from the Kensington Vestry for detailed information relating to any "abnormally high death-rate" within the parish. It will be interesting to see what action the vestry will now take in consequence of the "Notting Dale" disclosures.

It is impossible to over-rate the value of Dr. Dudfield's statistics relating to the local sanitary districts in Kensington, and it may be hoped that the medical officers of health of other metropolitan sanitary areas will follow his example. These statistics show that while the Kensington crude death-rate is deceptively low there are parts of the parish in which the death-rate is probably as high as in the worst parts of Holborn, St. Giles, or of East London. With regard to the low recorded death-rate in the whole of Kensington there can be no doubt that it is very considerably understated in consequence of the very high proportion of domestic servants included among the population of a large part of the district. This disturbing factor naturally affects the death-rate of females more than that of males. Mr. Thomas A. Welton recently read before the Royal Statistical Society an interesting paper on "Local Death-rates," which specially dealt with the disturbing influence of the immigration of young adults from rural districts to towns, a large proportion of whom in the case of illness return to their rural homes. This paper deserves the careful attention of the medical officers of health of both urban and rural districts.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 13, 1897.

THE voluntary hospitals of the metropolis should receive an enormous accession of strength from the action of his Royal Highness the PRINCE OF WALES in linking them with the event of the completion of the sixtieth year of HER MAJESTY'S unprecedented and glorious reign. It is gratifying to gather from the PRINCE'S letter that in bringing this project to the notice of the inhabitants of the metropolis he is able to commend it as one near to his own heart, and that he does so with the concurrence of Her Most Gracious Majesty the QUEEN. We have long advocated this cause—and did so again as recently as last week—as peculiarly fitted to command universal support and to be associated with a reign which has been so beneficent and sympathetic in its personal influence and which will stand out in history for ever-memorable advances in the art of healing.

The PRINCE in his letter, which has been before all our readers during the week, remarks on the fact that the finances of the hospitals of London have long been a source of anxiety and solicitude—a statement that is perfectly true, although we regret to see that the PRINCE has been misinformed as to the *amount* of the annual deficiency and has been induced to repeat the apocryphal statement about an annual shortcoming of from £70,000 to £100,000. He points out the small proportion of inhabitants that really contribute to the support of hospitals—less than 1 in 100. Excluding the half of the population that cannot give and having exclusive reference to the 500,000 households which have the means to contribute, he finds that 450,000 do not contribute anything to hospitals. This large number of persons, having the means to give to hospitals and not giving, is a subject for much study, and the PRINCE'S remarks are made with that mixture of kindliness and good sense which are always so apparent in his speeches. He does not attribute the not giving to mere indifference but to three other causes—partly to a difficulty of choosing the right institution, partly to the lack of an annual opportunity of giving annual subscriptions, and partly to the feeling that small sums are hardly worth contributing. There is force in these reasons. But they do not exhaust the explanation. There is at least a fourth which has grown in force rapidly of late and which must be met if the scheme of the PRINCE is to be worthy of his patronage and of the reign for which it is to be the chief metropolitan thank-offering. We refer to the laxness of hospital administration and the failure of hospital authorities to eliminate from their splendid and beneficent work all pauperising influences and all superfluous charity. The recognition of the need of provision for such elimination in the Royal scheme as it comes to be developed will add immensely to its strength and to the assurance of its success.

We assume, in our gratification with the main feature of the scheme, that it is open to modification in details and that the General Council may be slightly enlarged by the addition of those who would represent the strong desire to see a magnificent relief of the impecuniosity of London hospitals accompanied with a guarantee that necessary reforms of administration shall be a condition of receiving a share in the PRINCE OF WALES'S Hospital Fund for London. This brings us to the duty of criticising the more questionable parts of the scheme. There is one feature of it which we think the PRINCE on reflection will re-consider—that which extends it over a number of years; that which, in fact, makes it a continuous scheme in competition with the ordinary and regular channels of charity. Obviously the year 1897 has a charm and an emotion of its own which cannot be sustained. And the success of the PRINCE'S appeal will depend on taking this tide of feeling at the flood. A date should be set for the closing of the PRINCE'S Fund, and in our opinion not a remote one. The iron cools quickly and must be struck while it is hot. When the London citizen can in a given year at once show his loyalty to an incomparable Sovereign and his sympathy with a less fortunate brother or sister in hospital, there is no reason why every respectable hospital in London should not be relieved of all that is intolerable in its burden. But the appeal must stand out clear and well-defined from all others in point of time and of form. To prolong it will be, in our opinion, to endanger, if not to spoil, it. Apart from the objection that such prolongation would bring it into competition with common forms of appeal, there is another objection to extending the scheme over future years in the expense it would entail for the collection of an infinity of small sums. There are already indications that a large sum will be raised quickly in response to the PRINCE'S suggestion; but the sooner it is decided to mark the exceptional nature of the appeal the better, in our opinion, will be the result.

The PRINCE did well to frame his terms so as to include and invite those who can only give in shillings as well as those who can give in pounds. The widow's mite and the workman's shilling can be cast into this treasury, and none will be more gratified with such donations from slender purses than the illustrious Sovereign, for whose commemoration they are contributed, and her son, whose lasting honour it will be to have instigated so fitting a monument to her. This is a year when those whose modest wants of every day are met by the toil of every day can join with their richer brethren in testifying to the beneficence of QUEEN VICTORIA'S rule. Is it too much to hope of the accumulated and ever-increasing wealth of this metropolis that in this record year some big contributions to the Fund will soon be announced such as may show that liberality grows with wealth? Guy's Hospital was the work of one man. There are scores of men in London who could with little trouble wipe out the debt of every worthy hospital and fill the vacant wards with grateful and fit patients who are now being treated in ill-adapted homes. We have no wish to exaggerate the place of hospitals. We believe it will hinder this great commemorative movement if means are not taken to assure the public that the Fund shall not be used to perpetuate lax administration in hospitals. But no errors of administration can excuse those who have the means for not helping to make this Fund a splendid success in response to the gracious and charitable proposal of the PRINCE OF WALES and in commemoration of the reign of a

Hosted by Google

Sovereign who will be for ever distinguished for her many public and private virtues and, not least, for her sympathy with enlightened progress.

WHAT with plague, famine, and pestilence India is at the present time undergoing a terrible trial, but the sad condition of that country furnishes no ground for the state of more or less unreasoning panic with which some Governments and people seem to have been seized. We have no desire to minimise the gravity of the situation; indeed, no one who knows anything of the disease, even historically, and of the epidemic proportions it may assume, is likely to do so. But the accounts that have been handed down to us of the plague in past ages have left such an impression on the imagination that the events looming on us from India are very apt to arouse our fears to such a degree as to cause us to forget the very different conditions existing in 1665, for example, and those existing at the close of the present century. Then everything that could go to make up a hot-bed for epidemic disease was present; diseases were not differentiated from one another; the most elementary principles of sanitary science were unknown and their practice undreamt of; dirt, foul air, and overcrowding, which still so largely prevail in Eastern countries and cities, were then the rule everywhere; and the human race was, it may be said, dominated and terrorised in the presence of disease by one idea—the fear of contagion—from which the only possible safety was flight, such as we have recently seen amid the native populations of certain parts of India. The modern method of dealing with epidemics is very different and far wiser. We strive by all the means in our power to get at the facts and not view them in mis-shapen and exaggerated proportions through a fog of fears and prejudices of our own, the product very often of simple panic and a morbid imagination. That plague-infected persons can and do carry the disease with them is undoubted, but this is not all. Place and environing conditions probably play even a more important part than persons. It is, however, so much easier and cheaper to impose measures against the freedom of the person than to take steps against the insanitary conditions of a place that recourse is apt to be had to the former exclusively.

We really know very little about the plague beyond the fact that it is a virulent form of disease characterised by some very definite features, that it is very largely fatal in those attacked, that it is apt to spread and assume huge proportions in a population under given conditions, and that it is almost certainly contagious. But we know scientifically little or nothing at present of its true natural history, its exact cause and mode of origin, of the vehicles and agencies by which the disease-cause is carried and spread, of the period of its incubation, and so forth. The first thing, obviously, to be done under such circumstances—and there is no lack of courage and scientific enterprise on the part of the medical profession of this and other countries in this respect—is to boldly strive to study and investigate its nature and properties, making use in the meantime of all those weapons with which our knowledge of other epidemic infectious diseases has made us acquainted. At the present time we must adopt those precautions which common sense would indicate and such as have been found effective in the case of any other epidemic disease of an analogous kind. That is what has to be done, and, like other difficult things that have to be undertaken, we may as well set about doing it as calmly and thoroughly as we can. It is when we come to apply these principles to practice that difficulties arise; hence the adoption of international sanitary conferences. We quite recognise our international responsibilities and the duty we owe to other countries, but we cannot altogether close our eyes to the fact that the Governments of Europe envy British prosperity and are nothing loth to seize upon any occasion for imputing blame to this country. We agree with a remark in the *Spectator* that some Governments are capable, if anything could be gained by it, of declaring that famine is infectious. The proper course—that of an International Sanitary Conference at Venice—has been adopted with the view of fully considering the subject and of agreeing as to what should internationally be done. The present conference will not be the least important of the series and the complement of the others, its predecessors in 1891, 1893, and 1894 held at Venice, Dresden, and Paris respectively.

The Indian Government has already inaugurated a very vigorous policy. It has interdicted the departure of pilgrims from Bombay and Karachi. In addition to the close inspection of all passengers by rail from these ports, the supervision of all large towns and villages, the isolation of all cases of plague as soon as discovered, together with the segregration of those infected, and the destruction or disinfection of their houses have been undertaken. A measure has, moreover, been passed, with the approval of the Mussulman and Hindoo members of the Legislature, empowering all local governments to take any necessary steps for the suppression of plague without the necessity of reference to the Government of India. The possible invasion of the continent of Europe through the Persian Gulf, the unfitness and danger of Kamaran as a quarantine station, which, instead of being a safeguard, is far more likely, if all we hear of it be true, to act as a depôt for the concentration and diffusion of epidemic disease, are points which will require the attention of the Venice Conference. As regards Europe and the Suez Canal, we may remark that the bulk of the shipping passing through it is British, and if the risk of importing plague bears any relation to the amount and frequency of the communication with India, England should incur a greater risk than any other European country. It will, we presume, be possible to treat the Canal as a branch of the sea and to allow vessels from India to pass through it in quarantine without having any communication with the shore, and in this way to fulfil any international precautionary sanitary requirements. It is quite natural that the British delegates should not regard the question of quarantine and epidemic disease in exactly the same light as their Continental *confrères;* but it is very important that the subject should be regarded from every point of view and that some definite and reasonable line of international action should be agreed upon. Taught by experience, we in England have come to rely upon a combination of measures: precautionary, in the first place, against the introduction and dispersion of

Hosted by Google

disease-causes, and the protection of a population or locality, if and when invaded, by being sanitarily prepared for it. The British nation has been slowly but surely learning to lean more confidently upon the latter support, but it is quite a mistake to suppose that it altogether ignores and shuts its eyes to the former. Still, sanitation in its broadest and best sense is of slow growth: it means time and money, and Continental nations, with the enemy at their door, very naturally seek by quarantine and severely restrictive measures to close the door and shut him out. We trust that all the delegates will approach the discussion of the questions to be considered by them in a dispassionate and eminently conciliatory and reasonable spirit. A large number of men well qualified by their eminent position and reputation and by their administrative capacity and judgment will take part in the Venice Conference, and we confidently hope that some practical line of action may be the result of their deliberations.

WITHIN the last quarter of a century the laws relating to public health in Scotland have been, directly or indirectly, subjected to an amount of tinkering almost approaching that of the Factory Acts in England. Not only have there been directly some half-dozen Acts in amendment of the principal Act of 1867, but indirectly there have been at least two Local Government Acts, and a Burgh Police Act which itself took a good many years to gain admission to the Statute-book. In addition, of course, there have been such measures as the Notification Act, the Rivers Pollution Act, and the Housing of the Working Classes Act. It was the sincere desire of many who were interested in public health in Scotland that, when once the insufficiency and inconvenience of all this chaos of enactments had become impressed on successive Governments and when another Bill was in consequence to be brought before Parliament, that Bill should incorporate in itself everything that was useful in the existing measures and should add such new provisions as might be required. This desire has not been satisfied. Yet a great deal has been obtained, and the policy of asking for a silk gown in the hope of getting a sleeve has been justified. The policy, however, will have to be continued during the progress of the measure through Parliament, as there is still much required to make the Bill even fairly satisfactory. Last year, it may be recollected, the Secretary for Scotland began by introducing in the House of Lords an elaborate amending Bill, proposing at the same time to leave the principal Act unrepealed. The confusion threatened by this procedure was so self-evident that, under representations from various quarters and in spite of the eager support of a body of sanitary inspectors who ought to have known better, the amending Bill was quickly withdrawn. It was at once replaced by a Bill to abolish the existing Public Health Acts and to provide a substitute for them. This was described as a Consolidating Bill, and although it did not carry the principle of consolidation so far as it might have done, yet it was a vast improvement on the previous proposals. It passed the House of Lords, but time did not permit of its consideration by the House of Commons. Comparing that Bill as it entered the House of Lords with the Bill as now read for the first time in the House of Commons it is obvious that the two measures are essentially the same. Yet owing to amendments made in the Upper House and other amendments which have been made by the Government before presenting the Bill to the House of Commons there is evident a very considerable improvement in various parts of it.

In particular, the clauses relating to infectious disease have been much simplified. But it is just here that further amendment will be most urgently needed. It is proposed that all powers relating to infectious diseases shall apply only to such diseases as are brought under the Notification Act. The adoption of the Notification Act is to be made compulsory, which, of course, is entirely as it should be. But the Act does not include all infectious diseases, and the great majority of local authorities do not adopt for inclusion measles and whooping-cough. The effect of the clauses if passed in their present form will be that, unless measles is made notifiable in a district, the provisions for inspection of premises, and cleansing and disinfection, and the penalties with regard to exposure of infected persons, letting of infected houses, sending to school of infected children or children living in infected houses, and so forth, will not be applicable. The same remarks apply to all other infectious diseases exclusive of the minimum list contained in the Notification Act. However desirable it may be that Sanitary Boards should add to the diseases to be notified in their districts, this is not the way in which the matter should be dealt with. Two remedies suggest themselves. Clause 42 might be omitted altogether, leaving circumstances to decide which diseases should from time to time be considered infectious, or else a list of infectious diseases might be included in the clause, apart altogether from the Notification Act. At present the term infectious disease is not defined in the Scottish Public Health Acts, and absence of definition would be better than a definition which would so greatly limit the powers of sanitary authorities.

In the nuisance section there is a new provision of some interest. Among nuisances it is proposed that there be included "any refuse or manure contained in uncovered trucks or waggons standing or being at any station or siding or elsewhere on a railway so as to be a nuisance or injurious or dangerous to health." The object here is most praiseworthy, but the word "uncovered" is altogether objectionable. The throwing of a tarpaulin over a waggon-load of stinking offal would be apt to be looked on as equivalent to a special licence to allow the filth to continue for any length of time polluting the atmosphere in the vicinity of the station or siding, and, whereas at present complaints by residents or by local authorities may receive some attention from railway companies, under the Act as proposed the reply of the company might likely be that the Public Health Act was being carefully complied with. No attempt is made in the Bill to deal with dirty railway carriages. It is the duty of Parliament to take some steps to make railway travelling cleanly and reasonably safe against infection, but seeing that railway lines belonging to one company extend through the districts of hundreds of sanitary authorities and that the use of carriages is not limited to any one locality, the question is perhaps too broad to be dealt with by local bodies. Possibly the Local

Hosted by Google

Government Board or the Board of Trade might be the proper authority, but there is no doubt that good grounds exist for taking action in the matter.

Throughout the Bill various omissions are noticeable which can easily be rectified, as with regard to nuisances for which two or more persons are jointly responsible, the paving of common courts and passages, the levelling and macadamising of private streets in villages, the provision by local authorities of slaughter-houses in populous rural districts, the smoke-testing of drains, and the formation of port sanitary authorities. The Bill as it stands is a good Bill, but it requires many additions before it can be looked on as complete, and if Parliament desires to be rid for a reasonable period of public health legislation for Scotland it should see that no provision of obvious utility, the value of which has been proved by English or other experience, is left out of the new measure. We fully expect that before it reaches the report stage much will have been done to improve it in Committee.

Annotations.

"Ne quid nimis."

"SOME REMARKS ON PLAGUE."

WHENEVER an occasion arises for the discharge of professional duty or for affording a chance of enlarging our scientific knowledge of disease there is never any lack of courage and enterprise on the part of members of the medical profession—the men are always forthcoming. The epidemic outbreak of bubonic plague in India has not only caused, as might naturally have been expected, members of the medical services in that country to work with zeal and energy in the practical relief and attendance on the sick, but it has given a great impetus to bacteriological and scientific researches into the nature and treatment of that disease. Nor has this zeal been confined to India or England, for the medical profession on the Continent are keenly competing with us for the honour of adding something fresh and helpful to the common store of knowledge, and we are not surprised to learn that several scientific inquirers are proceeding to study plague on the spot. We would call attention to the paper by Dr. J. A. Lowson which appears in this number of THE LANCET on the subject of plague. Dr. Lowson has had the opportunity of seeing and treating that disease during its recent outbreak in China and is now on his way to Bombay, where in addition to the services he will render in the practical work of his profession he will have, we fear, ample opportunities of renewing his acquaintance with the disease and of adding, we trust, to our readers' knowledge of it by supplementing from Indian sources of observation the interesting remarks contained in his present paper in connexion with the Hong-Kong epidemic. Passing over Dr. Lowson's observations in regard to the nomenclature, distribution, and varieties of the disease known as pestis minor and pestis ambulans, we may briefly advert to those points in his paper in which he alludes to the methods by which infection leaves the body and the mode of carriage and spread of it. One certain but infrequent channel is by the discharge from buboes in which the bacilli are, he states, numerous and continue to be present with infecting powers for even some days during its purulent stage. Another vehicle of infection is the fæces, the culture-experiments made by Staff Surgeon Wilm in Hong-Kong having demonstrated the presence of the plague germ in these intestinal discharges; bacilli have also been found in the urine under certain conditions, in the sputum, and in the fur on the tongue. Dr Lowson is doubtful whether the secretion of milk is infective; many children suckled by their plague-stricken mothers were not infected. A similar observation was, it will be remembered, made in regard to cholera. He considers that there is little or no danger of infection from the breath of a patient suffering from plague, and cites a good deal of evidence in support of that view and in illustration of the freedom of attendants on plague-stricken patients from contracting the disease though breathing an atmosphere tainted with the expired air of these patients. Alluding to the curious localising effects and restricted sphere of influence of the infection noticed in the course of his experience at Hong-Kong, he thinks that the term "house infection" might in many cases be still more accurately termed "floor or flat epidemic." Dr. Lowson sums up the mode of infection in plague by saying that it may take place by inoculation, inspiration, or introduction into the stomach; the preponderating method will vary in different epidemics and will depend upon the opportunities presented.

THE MIDWIVES REGISTRATION BILL.

THE Bill for the registration of midwives was introduced in the House of Commons on Tuesday, Feb. 9th, by Mr. Egerton, and on that occasion was formally read a first time. The names appearing on the back of the Bill are those of Mr. de Tatton Egerton, Mr. Schwann, Sir Frederick FitzWygram, Mr. Skewes-Cox, Mr. Bonsor, Mr. Fenwick, Sir James Woodhouse, Mr. Harrison, Mr. John Wilson, Mr. Graham, Mr. Bill, and Mr. Heywood Johnstone. The Bill consists of sixteen clauses. The definition clause says that the term "midwife" shall mean "a woman who undertakes to attend cases of labour in accordance with the regulations to be laid down under this Act." The third clause, after laying down that no woman shall take or use the name of midwife unless she is registered, states that "the certificate of registration under this Act shall not confer upon any woman any right or title to be registered under the Medical Acts in respect of such certificate or to assume any name, title, or designation implying that she is by law recognised as a licentiate or practitioner in medicine or surgery, or that she is qualified to grant any medical certificate or any certificate of the cause of death." Further on the Bill proposes to set up a Midwives Board, to make rules for regulating the conditions of admission to the Register and the mode of conducting the qualifying examinations, to appoint examiners, to prepare and publish annually a register of midwives, to frame for approval by the General Medical Council rules for regulating, supervising, and restricting within due limits the practice of midwives, to decide upon the conditions under which a midwife may be suspended from practice, and to perform a number of other functions. In the ninth clause it is proposed that every local sanitary authority throughout England and Wales (the Bill does not extend to Scotland or Ireland) shall appoint its medical officer of health or other registered medical practitioner or practitioners as the local supervising authority over midwives in the sanitary district. Such is the outline of the Bill from which its tenour can be gathered. We shall proceed in ensuing numbers to deal with its provisions in detail.

DR. NANSEN ON THE PREVENTION OF SCURVY.

DR. NANSEN, in his lecture at the Albert Hall on "Some Results of the Norwegian Arctic Expedition," among other highly interesting matters touched upon one of great medical interest. We all know the difficulty that has been experienced, and has always to be encountered, on such expeditions, and frequently in those of a military nature, in

Hosted by Google

regard to scurvy, a malady which has hitherto been usually found to occur in Arctic explorations. Dr. Nansen ventured to [declare that it was very easy to avoid that disease by taking proper precautions, and he proceeded to relate his experience:—

"Dr. Torup, Professor of Physiology at the University of Christiania, had come to the conclusion, after examining the subject, that scurvy must arise from poisoning, caused, in particular, by badly preserved meat and fish. He thought that in the decomposition which takes place in the meat from bad preserving—in salt meat, for instance—there was poisonous matter allied to the so-called ptomaines, which, when constantly partaken of, engendered the malady we call scurvy. Particular attention was paid to this at the time of their equipment, and from their experience and the investigations he had the opportunity of making during the journey, he could entirely subscribe to Torup's opinion in this matter. It was to be hoped that in a near future there would be scientific elucidation of this important point; and it was equally to be hoped that certain means for avoiding this hitherto so fateful sickness might be shown."

Whether this supplies a key to the explanation of all the out breaks of scurvy that have occurred it would be premature to declare; but it marks a new departure and is well worthy of further investigation. Meanwhile, we think it may possibly account for some of the outbreaks about which a difference of opinion existed as to whether they were to be entirely explained by the absence of fresh vegetables.

THE NEW POOR-LAW SUPERANNUATION ACT AND MEDICAL FEES.

"YES," remarked an eminent politician to us the other day, "you doctors never look after your interests as a class; your work is so exacting that you have not the time, and thus when it happens that the interests of your class are in question you go to the wall." Medical officers in the Poor-law service are much exercised just now as to whether the extra fees which they receive for midwifery, amputations, vaccinations, &c., can be allowed to count as a basis for their future superannuation allowances as well as their fixed salary. The Act provides that the superannuation allowance to which an officer is entitled shall be based upon the average of his "annual salary and emoluments" during the five years prior to the date when he ceases to hold office, and the question raised is whether these fees form part of the "emoluments" of a medical man's office. We have already referred to this subject,[1] and on grounds already stated we have maintained that where a medical officer is also a vaccination officer the vaccination fees form part of the emoluments of his office, and should therefore be included as a basis for calculation. The Local Government Board, however, has expressed the opinion that as a vaccination officer only holds that office under a contract terminable on either side at a month's notice these fees cannot be included. As the matter now stands, therefore, the only way to get a final decision on the question of the vaccination fees would be to take the matter before one of the High Courts of Justice and get an authoritative interpretation of the Act on this point. Clerks to guardians, who are generally superintendent-registrars of births and deaths, stand in precisely the same position as regards their registration fees, but these gentlemen took good care in the framing of the Act that a special clause (Clause 19) should be inserted to the effect that "for the purposes of this Act superintendent-registrars and registrars of births and deaths are deemed to be in the service of the guardians of the union in which their districts are situated," and therefore the registration fees can be counted for superannuation. This precedent, it seems to us, is a very important one in considering the case of vaccination fees; but it also forms a very apt illustration of the advantage of looking after one's own interests. As regards the other medical fees, such as those for midwifery and major operations, we think there can be but little doubt—less doubt than in the case of vaccination fees—that these must be held to be included among the "emoluments" for purposes of superannuation, for they are "fees applicable to the office" of medical officer, and as yet no doubt has been thrown upon the fact that a district medical officer is an officer of the guardians. We understand, as a matter of fact, that percentages have already been deducted from these fees in the various unions, in view of their forming a basis for superannuation. In reference to the lunacy fees which some district and resident medical officers receive when called upon by the lunacy justices to examine and certify lunatics, these fees cannot well be included within the scope of the Act, because they are paid to the practitioner, not by virtue of his office as a medical officer, but by order of the justices in his capacity as an ordinary medical man. No special clause has been inserted to cover this difficulty as in the case of superintendent-registrars, and nothing short of fresh legislation can alter matters as regards lunacy fees. But in the case of vaccination fees we are of opinion that the grounds in favour of their being included are sufficiently strong to state a case for the interpretation of the Act upon this point in one of the High Courts.

[1] THE LANCET, Nov. 7th and 28th, 1896.

"MEDICAL ORIGINALS."

UNDER this heading a writer in a Russian periodical supplies some interesting details regarding the mode of life of an eccentric member of the medical profession, whose appearance was well known in the streets of St. Petersburg some half a century since. Having in the course of a somewhat lengthened career succeeded in amassing a considerable fortune, the physician in question, whose name is not given, decided on retiring from practice in order to pass the remainder of his days with dignity in the enjoyment of leisure. It happened, however, that his brain, so long accustomed to active exercise, proved unable to withstand the enervating effects of idleness. While the stimulus afforded by his daily ministrations to his sick and suffering townspeople continued in operation his faculties remained unclouded, but no sooner was this withdrawn than at once symptoms of mental deterioration began to show themselves. Being destitute of family ties he lived entirely alone, save for an antiquated crone, who was nominally his cook, although apparently she had but little whereupon to exercise her culinary talents. In addition to avarice the chief form of derangement with which the old gentleman was afflicted was dread of robbery. Formerly conspicuous for his gaiety he now became morose and suspicious to the last degree, fearing to leave his treasure for a moment, and unable either to sleep or to eat. According to the ancient dame he would assuredly have put an end to his misery by hanging if he could only have prevailed on himself to go to the expense of a rope. The means this aged monomaniac adopted to protect his beloved gold from thieves was truly remarkable. Having been medical attendant to the principal gaol he contrived to procure the skeletons of a number of malefactors who had been executed, and these he disposed around his premises in a way that unquestionably was calculated to strike terror into the heart of the boldest of burglars. In the first place, with his own hand he blackened the walls of the various rooms and passages, and having thus prepared the background he next arranged the lugubrious relics in a variety of attitudes all more or less startling. In the vestibule, for instance, he placed by way of a cloak-rack the skeleton of a woman who had cut the throats of her children. In the middle of the adjoining room stood the gigantic and minatory osseous remains of a Grenadier, who

Hosted by Google

had suffered the extreme penalty for murder. In lieu of a sideboard the dining-room contained a grim-looking erection fashioned out of human bones, plates and dishes resting on the pelves, and knives, forks, and spoons between the ribs, while the dome of a skull served as a sugar-basin and a child's ossicles as sugar-tongs. The appliances thus forbiddingly stored were, however, more for show than use, since their owner never by any chance entertained a guest and towards the end abstained almost altogether from eating. His death is ascribed to fear and hunger combined. A few moments before he expired he is said to have raised himself up in bed with great difficulty in order to blow out a candle; but whether he was actuated by a desire for economy or dreaded to afford illumination for the long-expected robber it is impossible to determine.

OYSTERS AND TYPHOID FEVER.

ACTING on the instructions of the Sanitary Committee, the medical officer of health of Brighton, Dr. Newsholme, has written to the medical officers of the thirty-three great towns of England and Wales, drawing attention to the danger of the spread of cholera and typhoid fever from sewage-contaminated oysters and other molluscs, and asking whether they would support a petition to the Local Government Board for legislation giving powers to local authorities to prevent the consumption of molluscs so polluted similar to the powers already in force for dealing with milk, or to take proceedings before the magistrate of the district in which the oyster-layings are situated, for the purpose of obtaining an order prohibiting their use until rendered fit for the purpose. Twenty-two answers had been received, nearly all in hearty support of the proposals. A petition on behalf of local authorities generally is to be prepared.

TUBERCULOSIS OF THE LUNGS IN ADVANCED LIFE.

PULMONARY tuberculosis when developed at a fairly advanced age, fifty years and upwards, often runs a very chronic course, and the acute form is but seldom met with at this time of life. In the *Centralblatt für Bakteriologie, Parasitenkunde und Infektionskrankheiten*, Jan. 20th, 1897, is a paper on this subject by Dr. A. M. Luzzatto. The presence of other micro-organisms, in addition to those pathognomonic of tubercle, is known to have a marked influence on the febrile phenomena and destruction of lung tissue, and Dr. Luzzatto's investigations were directed to the isolation of such bacteria. Fifteen cases were chosen, the patients being all over fifty years of age. In four cases scrapings were obtained from pulmonary cavities and the tissue of the lungs, and in eleven cases the sputum was examined, having been washed by Kitasato's method. In each case cover-glass preparations were made, cultivations were made on agar plates, and rabbits or guinea-pigs were inoculated. The following results were obtained. In eight cases colonies of streptococci were obtained on agar plates which always exhibited the same characteristics; the cocci were fairly large, not motile, stained well by Gram's method, and formed long chains, especially in broth cultures. The colonies were small, but often raised considerably above the surface; in only three instances could a broth culture be obtained, and sub-cultures were made with difficulty. The virulence of the fresh broth cultures was tried on two rabbits; in the first animal there was a slight local reaction; in the second no result followed. The streptococci were in two of the cases found to correspond with the staphylococcus pyogenes (aureus, citreus, and albus), and in all the cases with three forms of saprophytes; one was recognised as the micrococcus candicans (Flügge), the second as the bacillus fungoides (Tschistowitsch), and the third as a motile bacillus which could not be recognised as any known form. In the remaining seven cases the above-described forms of saprophytes were found in six and in the other case only the pathogenic bacilli were found. No definite relationship could be discovered either between the presence of the streptococci and the height of the fever or between the former and the existence of cavities and the course of the disease. In those patients over sixty years of age streptococci were never found. With the exception of two cases in which the animals died, in two cases of blood-poisoning (streptococcic infection), the sputum and contents of the cavities when inoculated were not virulent. The tubercle bacilli, however, caused death in from four to six weeks. Dr. Luzzatto concludes, therefore, that although, of course, pulmonary tuberculosis in old people has the same specific origin—namely, the tubercle bacillus—yet mixed infection is not nearly so common as in younger life, it being present in only about half the cases. Further, the micro-organisms which are found show only a slight degree of virulence and are not very tenacious of life; in short, we have to deal with an attenuated infection, and this explains to some extent the long and mild course which pulmonary tuberculosis usually exhibits in advanced life.

A DANGEROUS DELAY.

AT a meeting of the Uckfield (Sussex) rural council last week one of the sanitary inspectors made a statement which, if it be true, reveals an extraordinary condition of affairs. At one of the railway stations in his district, this officer declared, small-pox had broken out in the house of the station-master. Six children suffered from it, and at the time of the inspector's visit the station-master, not having been relieved by the company, could not leave his post. At the time one of the children, in the desquamating stage, was actually running about the platform, and it was only upon the inspector telegraphing to the authorities that the man was relieved. This state of affairs, with passengers through the place daily, was bad enough, but to make matters worse the man was also sub-postmaster! So that by rail and by letter this centre was capable of spreading the disease. It was proposed that the man should be prosecuted, but eventually an amendment to caution him was carried. It seems a case in which, surely, something should be said to the railway management—provided, of course, that the facts are as stated.

SCARBOROUGH'S SHAME.

A SERIES of admirable articles upon sanitary reform have recently been appearing in the *Scarboro' Post* which reveal a state of matters by no means creditable to the surely ironically styled "health committee" of that well-known watering place. From these articles it appears that the death-rate for the three years 1893-95 was as follows: England and Wales, 18·2; Birmingham, 19·9; Hastings, 14·2; Bournemouth, 13·2; Eastbourne, 12·6; Southport, 16·5; and Scarborough, 18·2. Of course part of this mortality is due to deaths of visitors registered in the borough, but the same remark holds good with regard to Eastbourne, Hastings, and especially Bournemouth. One great cause is not far to seek, but is contained in the following simple statement: Scarborough, 8900 houses—6500 privies. Some of these privies are actually *inside* the houses, and although the soil is removed weekly it still has to be carried through the houses. Several cases of this kind are alleged to exist within a few yards of the Town Hall; this being so it might urge the members of the health committee who talk about "sanitary fads" to action if the night soil were carried through the Town Hall when the said committee were sitting. Another crying want is an isolation hospital, the need for

Hosted by Google

which is forcibly set forth by the journal we quote from. This is, perhaps, a greater necessity than the abolition of the privy system; but, in our opinion, the two reforms should go hand in hand. "Obsta principiis" is the motto for those who have charge of the health of a community to bear in mind, and in no way can money be better spent than in sanitation. We earnestly hope that the medical officer of health will continue to press these reforms upon the health committee, and that the ratepayers also will do their share in demanding them. It is argued that the high death-rate, the privy system, and other abominations only affect the residents' and not the visitors' quarters; this may be true, but it is a very foolish argument. Firstly, the prosperity of a town depends mainly upon the permanent residents and not upon visitors; secondly, if these same visitors become acquainted with the state of matters revealed by the *Scarboro' Post* it is quite likely that their numbers will diminish to a vanishing point until sanitary improvements have been carried out. Everyone interested in Scarborough—and many are so—owes a debt of gratitude to the editor of the *Scarboro' Post*, and we hope soon to learn that the health committee has awakened to a due sense of its responsibilities.

A VILE TRADE.

MONSIEUR HENRI ROBERT of Paris is a man of filth. He is a disseminator of pornography and his circulars have recently been sent to certain members of the medical profession. We are able and willing to supply his full address so that the police of the gay capital may raid his premises and burn his beastly stock-in-trade, if there is any Act under which the French authorities are empowered to defend public morals to such an extent. We also desire to address a very serious word of warning to our readers. We know that members of the medical profession are not likely to be attracted by the lubricity of any circular. It is ignorance—not knowledge—that is fascinated by the wares of the pornographer. But certain of the advertisements have a semi-scientific appearance, and the medical writer might be tempted to purchase the books for other than lewd reasons. Let him not give way to the temptation. Traffic in these books may not be penal in Paris, but it is penal in England. The man Robert's circulars are posted in England. What is to prevent Robert from communicating to his agents in England the names and addresses of his English clients? On such an event blackmail would follow. The recipient of these circulars should send the letter and contents to the Postmaster-General and ask his Grace the Duke of Norfolk to earn everyone's gratitude by devising some scheme to prevent his Department being made the medium of incentive to vile immorality and even unmentionable crime.

GALVANIC DILATION OF EUSTACHIAN STRICTURES.

AN interesting application of electro-therapeutics in the treatment of aural disease is described by Dr. Arthur Duel in the *New York Medical Journal* of Jan. 16th. It consists in the employment of the negative pole of a galvanic battery for dilating constrictions of the Eustachian tube too tight to allow of ordinary inflation, after the method sometimes adopted in treating urethral stricture. Dr. Duel uses for this purpose fine copper bougies "securely mounted on No. 5 piano wire. These are passed through small insulated pure silver catheters and drawn back until the bulging portion of the bougie fits tightly in the mouth of the catheter." The other end of the wire is attached to a handle which connects it with the negative pole of a battery, the positive pole of which is in contact with the hand of the patient. The bougie is passed as usual along the Eustachian tube till it meets the constriction (as in the urethra there may be more than one of these). A weak current is slowly turned on and after from two to five minutes the bougie passes through the stricture with a slight pressure. It is then slowly withdrawn and the current gradually turned off before the catheter is removed. It is important that the current should be both opened and closed slowly. So far the results of this treatment are said to have been most satisfactory and Dr. Duel expects that the absorptive action thus illustrated will prove effectual not only in clearing the Eustachian passage in obstinate cases of constriction but also in causing resolution of hypertrophic deposits within the tympanum.

MIDWIVES' CORDIALS.

IN the course of an inquest touching the death of an illegitimate new-born infant at Broughton it transpired that the midwife, Mrs. Malcolm, finding the child cross and without sleep, ordered Mrs. Lord, one of the witnesses, to send to her house for a pennyworth of cordial. It was supplied by the servant and was compounded in this wise: a teaspoonful of Turkey rhubarb, a teaspoonful of magnesia, half a pound of loaf sugar, and a pennyworth of essence of linseed. The midwife from whom she had the prescription used to add laudanum, but she did not. The child died the next day after getting the cordial. Dr. Percy Hall, who made the post-mortem examination, said the child seemed to have died from bronchitis. He did not think the cordial contained laudanum. Both the coroner and the jury thought it wrong for midwives to prescribe. So do we. And such practices will have to be stopped.

AN EIGHTEENTH CENTURY PHYSICIAN.

IN the current number of the *Quarterly Review* is an article entitled "Eighteenth Century Reminiscences," founded upon a memoir of the Rev. Joshua Parry published in London in 1872 and also upon an unpublished MS. of his son, Caleb Hillier Parry, M.D. The latter was in many ways a very notable character. Born near Cirencester in 1755, the eldest son of a well-to-do and literary Nonconformist minister, both he and his father were intimate with the Mæcenas of the day—Allen, Lord Bathurst, to whom Pope dedicated his magnificent Epistle No. III. of the Moral Essays on "The Use of Riches." Caleb Parry's father died in 1776, and soon after the son migrated to Bath and became a fashionable physician. The western city was not then, as it became at a later date, given up to proprietary chapels and Christian charity, as exemplified by the refusal of sundry inhabitants to sit in the same room with a Roman Catholic, but was the resort of the leading literary and scientific men of the day—Herschel, Banks, and Jenner, and—distinguished in other fields—Lord Rodney and Lord Howe. Concerning the latter Parry has the following note. He was attending Lord Howe for a sharp attack of gouty pleurisy, with apparently some pneumonia. "I proposed a remedy," he says, "which, although new at that time to others in the treatment of highly inflammatory gout, had long been employed in that malady with the greatest success by myself. This was blood-letting." This was accordingly done and the patient much relieved. Howe thereupon asked if any good would come from repeating the operation, to which Parry replied in the negative, when Howe said, "I had yesterday no doubt that your proposal was right, and the event has shown that it was so. Now, let me give you one piece of advice. Deliberate well before you decide on any conduct; and, when you have decided, go straight on and never turn to the right hand or to the left." Admirable advice for anyone, but specially for a medical man. Parry furnished a number of sound contributions to medical literature; among others he was the first to describe.

Hosted by Google

exophthalmic goitre, of which disease he left an account of six cases, but for the outside world he is chiefly memorable as the father of Admiral Parry the Arctic explorer. Judging by the fragments of the MS. given in the article under consideration the possessor of it would confer no small benefit upon the reading public if he were to consent to publish the whole.

SERIOUS POLLUTION OF CHESHIRE STREAMS.

ON the 27th ult., at the Northwich county court, an application was made on behalf of the Northwich rural council for the removal of the suspension of an order requiring the Cheshire Alkali and Salt Co. of Middlewich to abstain from polluting the Rivers Dane and Croco and calling on them to show cause why a penalty of £20 a day allowed under the order should not be enforced. An affidavit stated that on Jan. 6th the two streams were white, apparently from lime refuse, and dead and dying fish were floating on the surface. The company's advocate denied the statements in the affidavit and pressed for time to complete preventive works. The judge said: "You have not filed a counter-affidavit. I saw this thing myself, and it is an intolerable nuisance which ought to be stopped." The advocate then stated that the company had bought ten acres of land and had plans for a reservoir which would cost several thousands of pounds. The judge: "I fail to see that I can do anything but remove the suspension and allow the penalty of £20 a day for every day the offence is committed to be enforced." There may, then, still be some hope that our streams and rivers will in time cease to be mere sewers.

SUBSTITUTES.

IT seems to us that the principal offence which is committed in trade nowadays is that of tendering substitutes, or the real article mixed with a proportion of substitutes, instead of the unsophisticated substance. That being so, the scope of the present Food and Drugs Act might well be simplified in accordance with modern requirements. In fact, we are almost inclined to think that the whole Act and its somewhat intricate clauses could be consolidated down to a very simple enactment. We would suggest, for example, that the seller should be required to supply exactly the article demanded and nothing else. If there should be any difficulty as to what a given term means let the State provide a definition. Thus the seller should be given to understand that when the buyer asks for "pure coffee" it should contain no chicory or other substance that is not coffee, that "butter" must be free from foreign fats, that "milk" must be the normal product of the cow, and Demerara sugar cane sugar not beet crystals, and so on. And we would extend this enactment to articles of clothing and other commodities. If a buyer asks for linen the seller has no right to tender him "linenette" or for flannel "flannelette." Nor should the seller tender anything in the nature of a substitute without informing the buyer to that effect. The fact that two things are of the same chemical composition, but in other respects different, is no justification for substitution, otherwise a vendor would be justified in offering oil of turpentine for oil of lemon, or oil of peppermint for oil of lavender. Yet the chemical composition of these substances is the same. So is that of beet sugar and cane sugar, but this does not justify a grocer calling his beet sugar Demerara or supplying his customer with beet sugar when he asks for cane sugar or Demerara crystals. We have not one word to say, be it food or article of clothing, against substitutes, but to supply a substitute against the knowledge of the purchaser is undoubtedly to commit a fraud, and sellers should be brought to understand this. That was the principle which at any rate, we rejoice to say, was upheld last week when the Islington vestry instituted a prosecution against a grocer for selling beet crystals as Demerara sugar. In giving his decision Mr. Bros said that it had been very strongly urged in this case that prejudice to the purchaser could not be proved, because the article supplied was alleged to be superior to the article asked for. The question for him to consider, as he very rightly pointed out, was not whether the article was superior to the article asked for, but whether it was of the same nature, substance, and quality. Though the article might be of the same nature and quality it clearly was not of the same substance. We welcome this sensible decision and congratulate the Islington vestry on having established a sound principle. We should like to see this principle extended to all other articles of purchase, so that the buyer may get what he asks for and not a substitute. A short Act based on this definition would comprehend all articles of trade, and not be restricted simply to articles of food or clothing. In short, it would be an Act to deal decisively and effectively with one branch at least of commercial immorality.

INFECTIVE MYELITIS.

IN the last number of the *Neurologisches Centralblatt* there is an abstract of a paper on this subject by Babes and Varnali. The writers restrict the term "myelitis" to true inflammatory processes, involving the vessels and connective tissue, excluding sclerotic or degenerative changes, and this, of course, postulates a virus for infective myelitis. From a consideration of other cases and of five which they themselves observed they consider that in such cases inflammation of bloodvessels is a necessary part of the process. Changes in the parenchyma of the spinal cord follow these changes in vessel. Especially do the toxin of the tubercle bacillus and the virus of syphilis cause such vascular changes. Micro-organisms, however, may without any affection of vessels penetrate the nerve cells, or surround them and gives rise to a peri-cellular inflammation in which the bloodvessels participate, as in hydrophobia, or in other cases, such as those of tetanus, the toxin may cause only alterations in the nerve cells. The paper is interesting and suggestive, especially in reference to the examination by cultures, &c., of the cords from cases of especially acute myelitis.

UNDERGROUND CELLARS AS BAKEHOUSES.

THE Factory and Workshops Act of 1895, like all other Acts of Parliament, is drawn so that a coach-and-four can be run through it. The Act provides that no bakehouse underground shall be permitted after January 1st, 1896. Mr. Berry, the medical officer of health for the County Borough of Wigan, finding that a bakehouse which was not in use on Jan. 1st, 1896, and had not been so from May, 1895, was re-opened as a bakehouse on Dec. 2nd, 1896, laid informations against the owner and also the occupier. The case being an important one was defended by Mr Horridge, barrister, of Liverpool, Mr. J. J. Charnock, Town Clerk of Wigan, appearing for the medical officer of health. The case turned upon the question as to whether this was a bakehouse in use on Jan. 1st, 1896, when the Act having reference to underground bakehouses came into force. Mr. Horridge submitted that they were entitled to use this underground bakehouse and said the question which arose was one of law. The Act which came into operation in 1896 did not interfere with existing rights, and although from that date the Legislature would not allow an underground bakehouse, yet the bakehouse in question had been in use from time to time, and on Jan. 1st, 1896, was merely waiting for a tenant. The magistrates who heard the case in Wigan Borough Police-court said that after considering the case they had decided that the cellar in question was used as a bakehouse and that the

Hosted by Google

cases would be dismissed. They, however, did not grant costs, as they thought it a proper case to bring forward. It appears, consequently, that once a bakehouse always a bakehouse, if the oven and other baking apparatus be left in and the place has not been used for any other purpose, no matter how long it may have been untenanted. Medical officers of health, therefore, will have difficulty in getting rid of these undesirable bakehouses, unless successful under the Public Health Acts. Evidently the new Factory and Workshops Act will not help them.

HONOURS TO MEDICAL MEN.

AMONG the recipients of honours just conferred by his Highness the Khedive appear the following medical men, whose names were brought prominently to notice during the late cholera epidemic in Egypt—viz, Mr. Harry Crookshank Pasha, Inspector-General of Prisons, and Dr. Rogers Pasha, C.M.G., Director-General of the Sanitary Service, who are both promoted to Grand Officers (Second Class) of the Imperial Order of the Osmanieh, and Dr. Pinching Bey, Sanitary Inspector of Lower Egypt, who becomes a Commander (Third Class) of the Order of the Medjidieh.

CHANGES IN THE BLOOD AFTER THYROIDECTOMY.

DR. POSTOEFF of Kharkoff has made a number of observations on the blood of dogs before and after the removal of the thyroid gland with the object of elucidating the changes which the extirpation of the gland produces in the blood. He divides the theories which have been propounded on this subject into two groups—the one supposing that the thyroid gland in its normal condition secretes some substance which is necessary to the proper working of the nervous system, and the other ascribing to the gland the secretion of some substance which directly destroys certain metabolic products, the accumulation of which in the blood would be fatal. His observations show that the extirpation of the thyroid gland is followed by a diminution in the red corpuscles, the hæmoglobin, and the specific gravity of the blood; an increase in the white corpuscles; a great increase in the fibrin obtained by whipping the blood; a diminution of nitrogen both in the blood and in the serum; and a marked diminution of nitrogen in the fibrin, not only relative, but absolute.

THE WATER-SUPPLY OF RICHMOND.

WE have received from Mr. John Cockram of Richmond (Surrey) a lengthy and detailed statement making serious complaints against one of the sources from which the water-supply of the town is derived. The importance of the issues involved, not only to the permanent residents, but also to the thousands of annual visitors from London, obviously requires that the responsible authorities should make known their reasons for feeling confidence in a source of domestic water-supply which at first sight appears to be not altogether above suspicion. The water distributed to this important town seems to be taken from four distinct quarters. The best is that which is pumped from a well 1446 feet deep, giving access to chalk strata and to Thanet sand; our correspondent assumes 224,000 gallons as a daily average yield therefrom. A further amount of 100,000 gallons is supplied daily by the Southwark and Vauxhall Water Company. The water complained of by our correspondent is estimated at a daily quantity of 200,000 gallons and comes from a shallow well at Petersham. This well "lies 56 ft. from the border of the Thames, in very low ground which is subject to inundation by the Thames. The bottom of the Petersham well is 11 ft. 6 in. from the surface. Richmond main sewer runs under the Thames towing path between the river and Petersham well. Although the land immediately surrounding the well is in its natural state, yet a large area of surface in the neighbourhood of Petersham and Ham—an area from which the well may fairly be supposed to derive some of its supplies—is made up of Richmond town refuse, which during seven years, and to the extent of about 45,000 tons, was deposited there in holes and hollows made in excavating gravel, and then the refuse was neatly covered over with turf. When the Thames overflows then this refuse must pollute the water at Petersham well, and when there is a drought Petersham supplies diminish seriously. On Nov. 17th, 1894, the flood rose 4 ft. above the top of Petersham well." The chief ground of complaint is that the water obtained from this questionable source is, previously to distribution, mixed with the better quality of water obtained from the deep well and from the London water company. If the facts are as alleged further investigation is urgently needed. Water drawn directly from the Thames is said to be used for flushing the sewers and sprinkling the roads.

UNIVERSITY COLLEGE HOSPITAL.

The festival dinner in aid of the funds of this charity was held at the Hôtel Cecil on Feb. 10th, when the Right Hon. the Lord Mayor presided. Among those present were the Lady Mayoress, His Excellency Baron Whettnall (the Belgian Minister), Lord Monkswell, Sir Douglas Galton, Sir John and Lady Hutton, Mr. B. L. Cohen, M.P., and Mrs. Cohen, Mr. H. F. Pollock, M.P., the Mayor and Mayoress of Richmond, Alderman and Mrs. Truscott, Mr. H. Lucas (chairman of the hospital committee), Mr. A. E. Barker, Dr. H. C. Bastian, Dr. Dudley Buxton, Dr. J. Rose Bradford, Dr. Radcliffe Crocker, Mr. R. J. Godlee, Dr. W. R. Gowers, Mr. Christopher Heath, Mr. Victor Horsley, Dr. G. B. Hunt, Mr. Raymond Johnson, Dr. Sydney Martin, Dr. G. Vivian Poore, Dr. Sydney Ringer, Dr. F. T. Roberts, Dr. H. R. Spencer, Sir Henry Thompson, Mr. Tweedy, and Miss Davenport Hill. In asking for funds the Lord Mayor said that some 47,000 persons were treated at University College Hospital in the course of a year, and that unless the hospital was more strongly supported by the benevolent public some of the beds would have to be closed. It is to be hoped that, as the Lord Mayor said, "the English purse is inexhaustible," and that not only University College Hospital, but all our great London medical charities will in this, the sixtieth year of Her Majesty's wonderful reign, experience practical proof of his lordship's dictum. Subscriptions to the amount of £5000 were announced by Mr. N. H. Nixon, the secretary, in the course of the evening.

THE NATURE OF YAWS.

MR. JONATHAN HUTCHINSON[1] states his present position on this much-debated question. It has been abundantly proved that there is disease prevalent in the West Indies, the Fiji Islands, at the Cape, in Ceylon, the East Indies, and many other localities which is specific and much the same in all places. It is propagated by contagion only. Inoculation experiments and observations have proved that a primary sore develops after an incubation period of about four weeks, followed by a general eruption at the end of from two to three months. This eruption is framboesial or raspberry-like in character. It tends to disappear and does not usually leave scars. Next follow sequelæ or tertiary symptoms. There may be bone disease, destruction of the nose, and intractable

[1] Edinburgh Medical Journal, January, 1897.

Hosted by Google

forms of skin ulceration resembling lupus. With the primary sore there are enlarged glands as in chancre. Most authorities assert that mercury and iodide of potassium are curative in the several stages, as in syphilis. On these facts there is no room for dispute. The debate centres on the relation to syphilis. Three opinions are possible: (1) that yaws is syphilis modified by race and climate; (2) that it is the parent stock from which European syphilis is derived, but that by long transmission the two have undergone some modification; and (3) that it has no real connexion, but depends on a specific poison of the same class which produces phenomena of a very similar kind. The latter is the opinion of almost all who have observed the disease in its native haunts. Experiment has proved that a patient who has recently had yaws may be inoculated with syphilis, and the same has occurred accidentally. On the other hand, in support of the belief that yaws cannot be anything but syphilis is the fact that it never comes to Europe as such. It seems impossible that a very contagious malady of prolonged duration, to which white persons as well as black are liable, which prevails over such extensive areas with which there is so much commerce, should remain for centuries restricted to its own districts.

THE FLUSHING OF CISTERNS.

WE have received from Mr. H. Carter, C.E., of Victoria-street, Westminster, a circular signed by himself and others calling attention to this subject.

"As a matter of public interest," the letter runs, "we have thought it our duty to call attention to the present action of some of the London water companies in serving notices on owners of houses to take out their three-gallons flushing cisterns and to substitute two-gallons cisterns. Although the water companies' regulations only permit a two gallons flush, the regulation has not been hitherto strictly enforced, at any rate, not in the better class of houses. As experienced sanitarians, we have been in the habit of recommending three-gallons flushing cisterns, being satisfied that a two-gallons flush is not sufficient to clear the closet trap and drain, however perfect their construction, and it is also well-known to us that most of the so-called two-gallons flushing cisterns do not discharge more than a gallon and a half."

We agree with Mr. Carter and his friends that a three-gallon flush is preferable to one of two gallons, but we think that in bringing so serious a charge against those responsible for the supply of fraudulent cisterns he should have given the names of the accused. Altogether, we should like more details, for if ever there was a time when the London water companies would be unlikely to wantonly annoy their customers that time is now.

THE SANITARY STATE OF THE ARMY IN INDIA.

WE have received a communication with reference to our leading article on "The sanitary state of the Army in India" (*vide* THE LANCET of Jan. 30th) in which the writer states that examination of the returns and the avoidance of theories demonstrate—as a mere question of figures—that the operation of the Contagious Diseases Acts had, if any effect, a reverse one to that alleged by us. "Prior to the Cantonments Acts there was," our correspondent writes, "an annual average decrease of 26 per 1000; under them an annual average increase of 14 per 1000; since repeal this increase has been reduced to 2 per 1000, to last published return." With regard to the first part of this statement we would simply say that all comparisons with the European Army in India as it existed before the short service system are, as our correspondent must know, quite valueless and misleading, as the circumstances were altogether different. Our remarks on the subject of venereal disease among the British troops serving in India were based upon figures given in published official reports as to the increased admission-rates for venereal disease. The subject was also referred to in the article from the *Pioneer Mail* extracted in the *Times* of Jan. 22nd last; and, as regards 1895, Lord George Hamilton, in reply to questions in Parliament, stated that the total aggregate admissions to hospital for venereal disease among the British troops in India amounted in that year to 522 per 1000—not 522 separate individual soldiers he went on to explain. Lord George Hamilton added that the facts as to the serious increase of this disease in India are now being inquired into. The Indian press has for some time past been calling attention to the large and increasing amount of this class of disease among the European troops in that country. It raises "the eyebrows of astonishment" to be told that these authorities are all wrong, but our correspondent must settle the matter with the officials of India, on whom we prefer to rely in the meantime for our statistical data. We cannot open our columns to a correspondence on the subject, for which we fail to see any need, as we presume from what has already taken place that the facts will soon be elicited in Parliament. We may, however, in the meanwhile, refer him to the *Pioneer Mail* of Jan. 14th, just to hand, for his edification.

AN AMERICAN SANATORIUM.

DR. T. J. MCGILLICUDDY directs attention in the *New York Medical Journal* of Jan. 16th, to the climatic advantages possessed by the west coast of Florida, and especially by the region of Tampa Bay. The traveller in search of health if he hails, as is usually the case, from a more northern latitude is advised to leave for the south about the middle or end of January and to stay at Tampa Bay till the end of April or the early part of May. During this period he should find the climate of the west coast of Florida mild, genial, dry, and equable, but possessed also of a bracing quality. The cases most likely to derive benefit from the change, we are told, are those of pulmonary and bronchial disease, with the necessary exception of advanced pulmonary tuberculosis. The conditions of domestic life are described as favourable, hotels and boarding-houses affording every comfort and convenience at reasonable rates. Good steamship and railway services exist. A warning is added against the dietary customs prevalent among the ordinary inhabitants of this district, which a brief glance at certain descriptive particulars is enough to justify.

MORE THAN THE MIGHT OF ARMED MEN.

AMID the number and variety of political and other events of a more or less sensational character which rapidly succeed one another we are apt to lose sight of some possessing a significance and interest of their own. They serve, however, to indicate the existence of a spirit which will survive and continue to grow when seemingly greater and more important occurrences are forgotten. Under the heading of "A Noble Knight" there recently appeared in the *Times* an extract from a letter received from India from Captain Leslie Younghusband, Inspecting Officer Imperial Troops, in which a little incident is recorded of the part played by Sir Portab Singh, K.C.S.I., the Regent of the Iodhpur State, Rajputana, and his brother. It appears that a young British officer in Iodhpur had fallen a victim to that disease which claims so many young European lives in India—viz., enteric fever. Sir Portab Singh and his brother personally aided in the last offices rendered to this young officer in helping to put his body into the coffin and carrying it downstairs to the carriage, and subsequently to the grave, as a mark of sympathetic respect to a brother soldier. What may seem, and would have been to one of ourselves, a small thing was, in reality, a large and remarkable one for a high-caste Hindu to perform. Sir Portab Singh is the Maharajah of an important native State, "a man of the highest caste and bluest blood of India, the genealogy of the family going back to before the Christian era." Lieutenant Cadell, the deceased officer, was not an official

Hosted by Google

employed at Iodhpur; he was not a personal friend of the Maharajah; he was simply a brother soldier for whom this Maharajah resolved to break his caste. This nation may well be proud of possessing officers who can manage whilst serving in India to engender feelings of this sort in the hearts of the highest native rulers, and grateful to Sir Portab Singh for such an exhibition of loyal feeling to them and to us.

REMOVAL OF SCARLET FEVER CASES IN CABS.

MRS. ELIZABETH WILLIAMS, Brynafon-terrace, Menai Bridge, and her mother, Mrs. Jane Davies, were fined lately by the magistrates of Bangor Police-court for removing their servant who was suffering from scarlet fever to Cyttir. Mr. Langford Jones, Bangor, testified to the facts, and said it was highly dangerous to the public to remove a patient in such a conveyance. Not only so, when the patient arrived at her mother's house no one was at home and she had to be kept waiting on the steps. An attempt to prove that the disease had not declared itself before the patient left her mistress's house failed. No steps up to the time of trial had been taken to disinfect the cab. The sanitary authority, the Ogwen District Council, would have failed in its duty had it not brought such facts to light.

THE ASYLUM WORKERS' ASSOCIATION.

THE Asylum Workers' Association, of which the late Sir Benjamin Ward Richardson was the first president, has among its objects the improvement of the status of asylum nurses and attendants and the provision of a "home of rest and nursing" for those engaged in asylum work. If carried out under proper medical supervision the education of asylum attendants in the special form of nursing required in asylums is an object worthy of support, and we welcome the first number of the *Asylum News* (the official organ of the association), which has been published with the intention of furthering the objects of the association. At the annual meeting of the association, which was held on Monday last, it was stated that the association now numbered upwards of 2000 members. The receipts for the year amounted to £107 2*s*. 6*d*. and the expenditure to £12 5*s*. 6*d*., leaving a balance in hand of £94 17*s*.

AT a recent meeting of the Committee of Graduates of the University of London, Mr. H. H. Cozens-Hardy, Q.C., M.P., the President, in the chair, the following resolution was unanimously adopted:—"That the Committee of Graduates of the University of London in favour of the scheme of Lord Cowper's Commission express the earnest hope that Her Majesty's Government will again introduce a Bill for the creation of a statutory commission for the re-constitution of the University of London and assure the Government that such a measure will have their active support."

THE official announcement of the conferment of a Peerage upon Sir Joseph Lister appears in the *London Gazette* of Feb. 9th as follows:—"Whitehall, February 8, 1897.—The Queen has been pleased to direct letters patent to be passed under the Great Seal of the United Kingdom of Great Britain and Ireland, granting the dignity of a Baron of the said United Kingdom unto Sir Joseph Lister, Bart., President of the Royal Society, and the heirs male of his body lawfully begotten, by the name, style, and title of Baron Lister, of Lyme Regis, in the county of Dorset."

MR. WYNTER BLYTH will lecture at the Sanitary Institute on Monday next, Feb. 15th, at 8 P.M., upon Factory Legislation.

WE are glad to note in the *Times* that at a Convocation of the University of Durham, held on Feb. 9th, it was agreed that the seal of the university should be affixed to a petition to the Queen for a supplementary charter to enlarge the penal power of the university in respect of the annulling of degrees and other matters.

THE Venice Conference having been postponed from Feb. 10th to the 16th, it is expected that Surgeon-General Cleghorn will arrive at Venice in time for the opening of the proceedings.

THE presentation of a testimonial to Sir William Broadbent will take place in the library of the medical school of St. Mary's Hospital on Wednesday, Feb. 17th, at 3 P.M.

HOSPITAL REFORM.

A PUBLIC meeting in connexion with this subject took place on Thursday, the 4th inst., at St. Martin's Town-hall, under the auspices of the Hospital Reform Association, Dr. J. WARD COUSINS in the chair.

In opening the proceedings the Chairman said they had met to consider a very important matter and one which he thought they could fairly say, as a Hospital Reform Association, they had determined to prosecute with wisdom and discretion. It was a subject of congratulation that since the formation of the association other societies and associations had become more active in the direction of hospital reform, particularly the Charity Organisation Society and the British Medical Association. There were, however, one or two distinguished features in the Hospital Reform Association, contrasting it with other kindred associations. In the first place, it was not confined to the metropolis, in addition to which it was open to all comers and not to members of the medical profession only. Another characteristic was that they were going to initiate suggestions and alterations in connexion with the management of the casualty and out-patient departments of hospitals. Those present would agree with him that it was only the really urgent cases of disease that required special skill, care, and observation, and were worthy of being treated in hospitals; whereas people labouring under small ailments and indifferent disorders often received subscribers' tickets, the consequence of which was that the out-patient rooms of hospitals were overcrowded. Referring again to the objects of the Hospital Reform Association, he said they were going to advocate no wage limit as regarded hospital relief. Personally he felt very strongly on this question, and one reason why he thought there should be no wage limit was the fact that the coöperative system was developing marvellously throughout England and respectable working men were enabled by their combinations in such societies to secure skilled attendance and the best medical advice. He thought there ought to be more affiliation, too, between these societies and the hospitals throughout England and Wales, so that in that way a large number of the common ailments of life might be dealt with at the homes of the respectable working classes. Again, more ought to be done to promote affiliation between all classes of medical practitioners.

Letters regretting inability to attend the meeting and wishing success in the pursuit of the objects of the association were then read, which had been received from Dr. J. G. Glover, Sir William Broadbent, Mr. Walter Rivington, and others.

Dr. ISAMBARD OWEN then proposed the following resolution, which, with slight modification, was declared carried:—"That the wholesale, indiscriminate, and hasty relief at present administered by many hospitals in out-patient and casualty departments is demoralising to the community, detrimental to the interest of true charity, unjust to the medical profession, and injurious to medical education, and that in the opinion of this meeting the time has arrived when the attention of governors of hospitals should be seriously given to the matter." He was glad to be in a position to respond to the

Hosted by Google

call to propose the resolution, being in some sort a representative of a London hospital in which the evils of indiscriminate medical charity had long been recognised. Touching on the statistics of the question, Dr. Owen then said that in the year 1895 more than 350,000 out-patients had been treated in the great London hospitals, while 455,000 patients had been returned as having been treated as casualties. Allowing for re-duplications in the reckoning of the patients, the conclusion could hardly be resisted that 500,000 persons during that year received out-door relief at the hands of the great London hospitals, and if to that number there were added 500,000 more who received relief at the smaller hospitals and at the special hospitals, a total would be reached which was truly appalling when one considered the proportion of these figures to the total population of London. But it was not only on the ground that indiscriminate relief was demoralising to those classes of the people to whom it was afforded that he recommended to them the resolution proposed; he appealed to them on the ground of the grave injustice to members of the medical profession who practised among the poor or among the comparatively poor. The system of indiscriminate relief to which he referred must be held responsible for a great deal of that lowering of medical remuneration which had become such an unfortunate feature of the condition of the medical profession of the present day.

Dr. FREDERICK SMITH, Dr. JESSOP, and Mr. NELSON HARDY then addressed the meeting in support of the resolution.

The Hon. SIDNEY HOLLAND, chairman of the London Hospital, said he thought it was a little bit unfortunate that the invasion, if he might call it so, should have come from Wales to London just at a time when all were trying to celebrate this great year by having a larger collection for hospitals than usual, and he thought it a still greater pity that a gentleman from Wales should write to the *Times* about the abuse of hospitals and give figures which it did not require an expert to show the fallacy of. He referred to the letter of Mr. T. Garrett Horder in the *Times* of the 2nd inst., in which he (Mr. Horder) had pointed out that the 2600 patients who attended a certain hospital were all cases which should not be treated, whereas he (the speaker) was perfectly certain Mr. Horder had had no means of investigating the position of those people, and he was quite sure that at that same London hospital the abuse which people so blindly talked about hardly existed. He knew he was speaking in the presence of people who were all in favour of their own notions, but all he could say was that he had spent day after day in the out-patient department and had stopped every person almost whom he thought was at all in a position to pay, with the result that he had been pained and surprised and grieved at the absolute misery and destitution of the people who were treated. To write to a paper like the *Times* and give a list of butlers and ladies' maids who had been treated as a sample of the class treated was an abuse of the power of writing to the press. He was the grandson of a medical man, and was the last in the world to wish harm to the profession, and he was also now one of the managers of three hospitals and the chairman of three, and he distinctly said it was not with them that the abuse existed. The difficulty was to get the staff to do anything. One of the previous speakers (Dr. Frederick Smith) had talked about the out-patient department, but he (the speaker) had had the pleasure of meeting with him and had talked with him on various matters connected with it and he had never heard Dr. Smith say a word till then about it at all. If he (the speaker) were asked to increase the staff of the hospital they would all be up in arms against him at once; but if the hospitals were a benefit to the poor let them have bigger staffs and so get more time. If it was a question of pay and the staffs were not paid, put that down to those responsible for it—that was one important part of the association's objects. He did not know that the staff wanted pay—he thought the hospitals had been useful to the staff. He had always believed that hospitals did a great deal of good for patients, but he had yet to learn they had done any harm to medical men. Of course, he knew that East-end practitioners did not get West-end fees, but still the fees often were a very great deal more than the patient could afford to pay. He was quite ready to believe that the out-patients should be charged something. It was said that to do so would take it out of the outside practitioners' pocket, but he (the speaker) thought much more harm was done to the outside practitioner by not charging than by charging. Some of the poor in the East-end had not much faith in the outside practitioner, and some of them were justified in their opinion. As to whether they thought more of the outside practitioner than of the hospital, the proof of the pudding was in the eating, and they preferred to come and wait many hours to have themselves attended to on the cheap. This showed that Dr. Smith was wrong when he said they could pay. In conclusion he would say that it was not right to make the general statements on the subject which had been made and let it go out to the public that there was great abuse of hospitals when they knew how willing people were to stop their subscriptions and to take every possible excuse to stop them. Responsible people like those present should take steps like these with some care and thought and should approach the staffs of hospitals and get those to help who were members of their own profession, and not appeal to the public at meetings held by gentlemen unconnected with London hospitals.

Mr. TIMOTHY HOLMES in the course of his remarks said that speaking from his own experience at St. George's Hospital there were very few people indeed who could afford to pay anything like a reasonable fee. He did not believe that the abuse of the out-patient department would be found to lie chiefly in the direction indicated—viz., that persons came there who were able to pay; but at the same time there might be a certain amount of abuse in that way. What seemed to him the most striking abuse in the out-patient department was that the greater part of the treatment was ill-directed; the affections treated there, and a good deal of the surgical practice, too, was directed to the treatment of diseases which ought not to be treated—as they must be in a hospital—by a short consultation and a bottle of physic. A great deal of work was thus done which produced very little result. There ought to be more time given to the cases and they ought to be different cases.

Other speakers having addressed the meeting the proceedings were brought to a close by a hearty vote of thanks to the chairman.

ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1895.[1]

[SECOND NOTICE.[2]]

THE average strength of warrant officers, non-commissioned officers, and men who served in the United Kingdom in 1895 was 99,795, and in addition the number of men detached from their corps averaged 3911.

1895.	Ratios per 1000 of strength.				Average sick time to each soldier.	Average duration of each case of sickness.
	Admissions.	Deaths.	Invaliding.	Constantly sick.		
					Days.	Days.
England and Wales	718·9	3·95	17·12	43·68	15·94	22·18
Scotland	591·1	3·66	14·21	26·51	9·68	16·37
Ireland	669·9	5·59	15·30	38·13	13·92	20·77
United Kingdom	702·8	4·32	16·57	41·76	15·24	21·69

In comparison with the corresponding ratios of the preceding ten years a decrease is shown in the admission rate of 68·3, in the mortality rate of 0·88, and in the constantly sick rate of 2·19 per 1000. The total loss by death and final discharge from the service on account of medical unfitness was 2167 men, equal to a ratio of 20·89 per 1000 of strength, only fractionally above the rate in the previous year.

[1] Army Medical Department Report for the Year 1895, with Appendix. Vol. xxxvii. London: Printed for Her Majesty's Stationery Office by Harrison and Sons, Printers to Her Majesty. 1896. Price 4s.

[2] The first notice appeared in THE LANCET of Jan. 30th, 1897.

Hosted by Google

There were three cases of small-pox recorded during the year; two of the patients bore good marks of vaccination, the disease was of modified type, and ran a favourable course; in the third, who was a recruit and had not been vaccinated in the service, the disease ran a severe and confluent course.

Enteric fever gave rise to 137 admissions and 35 deaths. In Scotland there were 3 admissions and no deaths, in England and Wales 73 admissions and 22 deaths, and in Ireland 61 cases and 13 deaths. Island Bridge Barracks (Dublin) were vacated during the year on account of the number of cases occurring there and the drainage system was disinfected and remodelled, but it is believed that the insanitary surroundings have far more to do with the prevalence of the disease than any defects within barracks.

Taking all forms of venereal diseases together the ratios for the United Kingdom were 173 8 for admissions and for constant inefficiency 15·28 per 1000, being a decrease on preceding years. The Channel Islands gave the highest ratio—230·1 per 1000. The district showing the lowest admission rate was that of Cork.

The influence of age and length of service on the sickness, mortality, and invaliding of soldiers serving in the United Kingdom is set forth in tables. The sequence of the ratios in these respects is very much the same as in previous years.

As regards different arms of the service it appears that the highest admission-rate was 840·1 in the infantry, the next being 739 5 in the Household Cavalry, the lowest in the garrison staff and departments; the highest mortality-rate was in the regimental depôts (5 83), followed by the Royal Engineers (5·53); the lowest was in the infantry (3·81). Invaliding was highest in the Household Cavalry and in the Foot Guards—34 62 and 22·83 per 1000 respectively.

Turning to the recruiting of the army we find that the total number of recruits inspected in 1895 was 55,698, of which number 32,782, or 588·57 per 1000, were found fit for service. England and Wales supply by far the larger number of recruits, followed by Ireland and Scotland. Defective vision, diseases of the heart, loss or decay of many teeth, and defects of the lower extremities are prominent causes of rejection; but the main causes come under deficient chest measurement, height, weight, &c. As regards the state of education of the recruits finally approved, it appears that 63 per 1000 are well educated and 902 per 1000 are able to read and write.

Passing to the health of the troops serving in the Mediterranean there is not much to be said about Gibraltar. The ratios are much the same as they were in 1894; the admission and constantly sick rates are somewhat higher than the average of the preceding ten years, but the death-rate has declined by 1 06 per 1000. It is remarked in connexion with enteric fever that no case was admitted from the South Barracks, where certain sanitary improvements had been effected, which in 1895 (1894?) gave the largest number of admissions. One soldier died from hydrophobia at this station; he was bitten by a dog in October, 1894, and the wound healed after cauterisation; on Jan. 28th, 1895, he felt unwell, and died on the 31st with well-marked symptoms of the disease.

Malta, with an average strength of 8292 (excluding the Royal Malta Artillery), was not so healthy in 1895, although there was less prevalence of enteric fever, as in the previous year or in comparison with the average rates for the previous decennium. The following table shows the sickness and mortality in the command during 1895:—

1875. Average strength.	Ratio per 1000 of strength.				
	Admissions.	Deaths.	Invalids sent home.	Invalids finally discharged	Constantly sick.
8292	771·5	6·87	14·71	8·32	55·17

Fevers of a more or less continued type, together with enteric fever, prevailed, and there was a good deal of venereal disease, 192 cases of which were imported into the station—mostly from India—during the year. There seems, also, to have been a good deal of sickness among the officers, women, and children during the year at this station.

THE PLAGUE IN INDIA.

As regards the plague in India the latest intelligence does not show any abatement or decrease in the extent of prevalence of the epidemic. At Karachi and Poona, on the contrary, the disease is said to be increasing. Still, the total mortality from the plague in India from its commencement to the present time, deplorable as it is, bears no sort of comparison with that recorded of the great epidemics of a few centuries ago. We infer from the official report of the Governor of Bombay that the state of public feeling in that city is somewhat more hopeful. The hospitals are more freely resorted to; and for the week ending Jan. 29th there had been a diminution of deaths from plague and in the number of total deaths from all causes, but it must be added that there has been a very large decrease in the population owing to the exodus which has taken place. There were 245 deaths recorded in Bombay on the 1st of the present month, and an alarming outbreak of plague had taken place in the gaols and the removal of the prisoners was contemplated. In those districts and quarters of the city where the disease had been worst it had either been suppressed or had decreased, while it had been extending to other quarters. Very great activity had been, and is still being, displayed in providing for the segregation of the sick and the removal and accommodation of healthy people who had been exposed to infection and for the disinfection or destruction of infected houses, and the cleansing, disinfection, and sanitary improvement of the city generally. We gather that the drainage of Bombay has long been defective in that there was more water coming into the city than was removed from it, and that there was a great deal of water running to waste and productive of a water-logged state of the soil owing to imperfect house connexions and the ignorance of the natives. The disease prevails mainly among the native and poorer classes of the population occupying the more crowded districts of the city. The attacks among Europeans have been relatively very few. According to the official returns there had been up to Feb. 4th 5098 cases of plague in Bombay and 3841 deaths. The week's mortality from all causes amounted to 1645. The disease still prevails at Poona and Karachi and sporadic cases of plague are stated to have appeared elsewhere. In Poona, where fifty-eight indigenous cases had been reported, forty-eight occurred in one quarter. No cases had occurred in the cantonment. The latest intelligence from Poona and Karachi is, as we have said, to the effect that the disease is increasing, the number of seizures and deaths at the latter place greatly so. Calcutta, so far as is known at present, remains free from plague.

It is reported that many cases, some of which have terminated fatally, have occurred at Goa and Daman, and that the Portuguese authorities have adopted very severe and stringent measures for its suppression. A report is stated to have been received from the Governor of the Transcaspian territory announcing that plague has broken out at Kandahar; and a Russian force, under General Youoff, composed of Cossacks, the troops of the frontier guard, and Bokharan troops, has been instructed to keep a watch along the Amu Daria and establish a military cordon.

We think that in the case of what are termed *bustees* and certain foul and overcrowded native quarters in cities the simplest and best course would be to destroy them, where safe and practicable, by fire instead of pulling down and demolishing them. It also seems desirable, where it can be done, to utilise tents and huts on freely exposed sites outside a city as a means of accommodating any excess of population and lessening any overcrowding. When a case of plague occurs in a house it is better to vacate the house and remove the unattacked occupants, segregating them for a time in places specially set apart for their accommodation. They are not likely to act as fresh foci of contagion to other people provided their surroundings be healthy and the sites clean, open, and exposed. The soil is the great vitaliser of the plague bacillus. There is no more powerful factor for inviting the incidence or increasing the prevalence and virulence of any epidemic disease than overcrowding. All ocean-going vessels leaving Bombay are medically inspected before starting. Pilgrim ships have been prohibited from leaving Bombay since the 1st inst.

THE BATTLE OF THE CLUBS.

WE are glad to see that South London—or at all events Battersea and Clapham—is organising against the pressure of the Clubs. The "Battersea and Clapham Medical Service" is managed by an executive committee consisting of the medical attendants only, and this committee is to have sole control over the affairs of the Service. There are some very admirable rules, of which the third is perhaps the most important.

3. Persons wishing to become members must make a declaration to the collector that they are unable to pay for medical attendance in the ordinary way and that they are not suffering from any kind of illness, whether acute or chronic. If this declaration is afterwards found by the committee to have been untrue, those whom it concerns will be immediately expelled and all contributions paid will be forfeited.

The payments are 1*s* a quarter for membership and 1*d*. a quarter for management, in addition to 1*d*. for every new card of membership. The highest amount payable for any number of children under twelve belonging to one family is 4*d*., and the highest management fee payable by one family is 4*d*.

Rule 9 may be an excellent one in theory, but we do not see how it is to be carried out in practice.

9. Any member who may have contracted an illness by his or her own fault shall not be entitled to medical attendance for the same on the terms of the service.

The medical attendants, eight in number, are given at the end of the book of rules. We notice that whatever their qualifications they are all styled "Doctor," though some of them have no degree, but doubtless the gentlemen to whom these remarks refer will see the propriety of altering this mistake in the next edition. Meanwhile we wish the new "Service" every success.

A correspondent writes to us enclosing a circular setting forth the benefits, scales of payment, and other matters which obtain under the "Cripplegate Benefit Society for Women." Our correspondent says:—

"I enclose a circular sent to me with an invitation to become a medical officer to the Cripplegate Society for Women at the remuneration of 4*s*. per member per year. I have declined the honour on the grounds that the medical officer agrees to attend those who can only afford to join under Scale I. and those better off who can afford to pay under Scale VI. at the same rate; also that the medical officer has no option but to attend any member, no matter what her social position; and lastly, that our local women's society pays its medical officer 6*s*. per member per year, and with the medical aid clubs in this district meets all the requirements of the working-classes for medical attendance."

We think he is quite right. Under Scale 1 the weekly payments to obtain benefits are, if the applicant is aged eighteen, 4*d*. per week; if thirty-five, 5*d*. Under Scale 6 the weekly payment at eighteen is 1*s*. 5*d*.; at thirty-five, 2*s*. 8*d*. It is manifestly absurd that persons who can afford to pay such vastly larger sums in the one case should only pay the same sum for medical assurance as their poorer sisters; also, there is no doubt that the medical officer should have the option of refusing to attend any member if he thinks her an unfit subject for charity. Friendly societies are excellent institutions in many ways, but when they are constructed so as to grind the faces of struggling medical men, who are in some ways the worst paid class in the community, it is time for the said class to make a stand.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE WEBER-PARKES MEDAL.

OUR readers may be interested to see the accompanying illustration of the medal which has been designed to accompany the award of the Triennial Prize founded by Dr. Hermann Weber in memory of his friend, the late Dr. E. A. Parkes. The award is, it may be recalled, to be made for the best essay on subjects connected with the Prevention and Cure of Tuberculosis, and the competition is open to the whole world. The subject for the first competition was announced about twelve months ago.

The obverse bears the portrait of the founder in profile to the left with his name and the date of the foundation, 1894. On the reverse Demeter, Heracles, and Apollo are represented standing before a seated figure of Asklepios. Below is the inscription: "Prevention and Cure of Tuberculosis," and above we read, "Weber-Parkes Prize Medal." The idea of the reverse, which is Dr. Weber's own, is that

FIG. 1.

Obverse.

FIG. 2.

Reverse.

the physician represented by Asklepios, the Greek god of medicine, makes use of light and climate (Apollo, the Greek sun-god), food (Demeter, the earth-goddess), exercise and drainage (Herakles, the god of strength and cleanser of the Augean stables) in the prevention and treatment of tuberculosis. The medal (two inches in diameter) is the work of Mr. Frank Bowcher.

THE ARMY ESTIMATES FOR 1897-98.

MEDICAL officers and others will be turning to the Army Estimates to see if they can discover in its pages any indications of coming changes in the Army Medical Service. The estimates for medical establishments, pay, &c., required for the year ending March 31st, 1898, show little difference, however, from those of last year. The sum estimated in Vote 2 is calculated at £295,800, being an increase of £1000 on that of last year. The total establishment of medical staff of all ranks is 948—one less than in 1896-97. Of this number 335 are on the Indian establishment. The total numbers and pay of the medical staff, British establishment, amount to 613, at the estimated cost for 1897-98 of £233,200, divided between £178,750 for home and £54,450 for colonial service respectively.

The pay of militia medical officers and civilian practitioners for the ensuing official year is estimated at £10,600. The cost of the Medical Staff Corps, nurses, clerks, and other subordinates is taken at £38,000, as against £37,000 in

Hosted by Google

1896–97. The cost of medicines, surgical instruments, &c., is calculated at £14,000, the same as last year. The Army Medical School at Netley comes under establishments for military education, and its estimated cost amounts to £7900 for the year 1897–98. The headquarter office establishment consists of a director-general, one surgeon-major-general, one brigade-surgeon-lieutenant-colonel, and two surgeon-majors and surgeon-lieutenant-colonels. In the Secretary of State's covering memorandum on the Army Estimates for 1897–98 it is stated that although the number of recruits raised in 1896 is about 1000 less than in the previous year the difference does not arise from any difficulty in obtaining men, for the authorised establishment has been fully maintained without any alteration of the standard of height. The percentage of special enlistments of men not conforming in every way to the standards now numbers only 18 per cent., as against 19·9 per cent. in 1895 and 25 4 per cent. in 1894, which is satisfactory so far as it goes.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6536 births and 4375 deaths were registered during the week ending Feb. 6th. The annual rate of mortality in these towns, which had increased in the three preceding weeks from 19·2 to 20·6 per 1000, further rose last week to 20·8. In London the rate was 20·6 per 1000, while it averaged 20·9 in the thirty-two provincial towns. The lowest rates in these towns were 11·3 in Huddersfield, 14·2 in Croydon, 14·6 in Newcastle-upon-Tyne, and 16·3 in Halifax; the highest rates were 24·7 in Oldham, 25·2 in Liverpool, 25·3 in Bolton, and 27·2 in Manchester. The 4375 deaths included 361 which were referred to the principal zymotic diseases, against 386 and 366 in the two preceding weeks; of these, 132 resulted from whooping-cough, 69 from diphtheria, 51 from "fever" (principally enteric), 45 from diarrhœa, 34 from measles, 30 from scarlet fever, and not one from small-pox. No fatal case of any of these diseases was recorded in Norwich or in Huddersfield; in the other towns they caused the lowest death-rates in Newcastle-upon-Tyne, Croydon, and Cardiff, and the highest rates in Hull, Bradford, Blackburn, and Burnley. The greatest mortality from measles occurred in Plymouth and Bradford; from whooping-cough in Bristol, Swansea, Nottingham, Blackburn, Burnley, and Sunderland; and from "fever" in Gateshead, Halifax, Wolverhampton, and Hull. The mortality from scarlet fever showed no marked excess in any of the large towns. The 69 deaths from diphtheria included 46 in London, 5 in West Ham, 5 in Birmingham, and 4 in Leeds. No fatal case of small-pox was registered in any of the thirty-three large towns. There were 21 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 6th inst., against 3, 2, and 9 at the end of the three preceding weeks; 12 new cases were admitted during the week, against 1, 0, and 7 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3153, against 3414, 3354, and 3311 on the three preceding Saturdays; 245 new cases were admitted during the week, against 208, 249, and 254 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had increased from 306 to 355 in the three preceding weeks, further rose to 404 last week, but were 81 below the corrected average. The causes of 65, or 1·5 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Oldham, Newcastle-upon-Tyne, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·6 and 24·3 per 1000 in the two preceding weeks, rose again to 26·6 during the week ending Feb. 6th, and exceeded by 5·8 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 22 3 in Dundee and 22 6 in Aberdeen, to 37·5 in Perth and 44·0 in Greenock. The 792 deaths in these towns included 96 which were referred to the principal zymotic diseases, against 89 and 81 in the two preceding weeks. Of these 32 resulted from whooping-cough, 28 from measles, 20 from diarrhœa, 7 from scarlet fever, 5 from diphtheria, and 4 from "fever." These 96 deaths were equal to an annual rate of 3·2 per 1000, which was 1·5 above the mean zymotic death-rate during the same period in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 26 and 28 in the two preceding weeks, further rose to 32 last week, of which 23 occurred in Glasgow and 5 in Edinburgh. The deaths referred to measles, which had been 28, 36, and 28 in the three preceding weeks, were again 28 last week, of which 24 were recorded in Glasgow, 2 in Aberdeen, and 2 in Perth. The 7 fatal cases of scarlet fever exceeded by 2 the number in the preceding week, and included 3 in Glasgow. The deaths from diphtheria, which had been 8 and 2 in the two preceding weeks, rose again to 5 last week, of which 4 occurred in Glasgow. The 4 deaths referred to different forms of "fever" were below the number in any recent week. The deaths from diseases of the respiratory organs in these towns, which had been 162 and 190 in the two preceding weeks, further rose to 229 last week, and exceeded by 113 the number in the corresponding week of last year. The causes of 61, or nearly 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 43·9 and 42·4 per 1000 in the two preceding weeks, rose again to 44·2 during the week ending Feb. 6th. During the past five weeks of the current quarter the death-rate in the city has averaged 40·1 per 1000, the rate during the same period being 19·0 in London and 22·0 in Edinburgh. The 296 deaths registered in Dublin showed an increase of 12 upon the number in the preceding week, and included 52 which were referred to the principal zymotic diseases, against 57 and 46 in the two preceding weeks; of these, 24 resulted from whooping-cough, 18 from measles, 4 from scarlet fever, 3 from diarrhœa, 2 from "fever," and 1 from diphtheria. These 52 deaths were equal to an annual rate of 7·8 per 1000, the zymotic death-rate during the same period being 1·7 in London and 1·6 in Edinburgh. The fatal cases of whooping-cough, which had been 27, 23, and 27 in the three preceding weeks, declined again to 24 last week. The deaths referred to measles, which had been 15 and 7 in the two preceding weeks, rose again to 18 last week. The 4 fatal cases of scarlet fever were within 2 of the number in the preceding week, while the 2 deaths referred to "fever" corresponded with the number recorded in the preceding week. The 296 deaths in Dublin last week included 65 of infants under one year of age and 57 of persons aged upwards of sixty years; the deaths of infants showed a further increase upon recent weekly numbers, while those of elderly persons showed a decline. Five inquest cases and 6 deaths from violence were registered; and 84, or more than a fourth, of the deaths occurred in public institutions. The causes of 19, or more than 6 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING JANUARY, 1897.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during January in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 9·0 per 1000 of the population, estimated at 4,463,169 persons in the middle of this year. In the three preceding months the rates had been 14·6, 12·6, and 10·7 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in St. George Hanover-square, St. James Westminster, Hampstead, Strand, City of London, Lee, and Plumstead; while they showed the largest excess in St. Giles, Clerkenwell, St. Luke, Shoreditch, Bethnal Green, Mile End Old Town, Poplar, and St. Saviour Southwark. Eight cases of small-pox were notified in London during January, against 2, 0, and 3 in the three preceding months. There were 8 cases of small-pox under treatment in the Metropolitan Asylum Hospitals at the

Hosted by Google

end of January, against 2, 1, and 3 at the end of the three preceding months; 7 new cases were admitted during the month. The prevalence of scarlet fever in London showed a further decline from that recorded in recent months; this disease was proportionally most prevalent in Fulham, Hackney, St. Giles, Clerkenwell, Limehouse, St. Saviour Southwark, and Wandsworth sanitary areas. The Metropolitan Asylum Hospitals contained 3246 scarlet fever patients at the end of January, against 4054, 3932, and 3601 at the end of the three preceding months; the weekly admissions averaged 245, against 398, 356, and 355 in the three preceding months. The prevalence of diphtheria in London showed a further decline from that recorded in the three preceding months; among the various sanitary areas this disease showed the highest proportional prevalence in Islington, St. Luke, Bethnal Green, St. George-in-the-East, Mile End Old Town, Poplar, Woolwich, and Camberwell. There were 897 diphtheria patients under treatment in the Metropolitan Asylum Hospitals at the end of January, against 780, 777, and 829 at the end of the three preceding months; the weekly admissions averaged 105, against 105, 110, and 119 in the three preceding months. The prevalence of enteric fever in London also showed a further decline from that recorded in recent months; this disease was proportionally most prevalent in Clerkenwell, St. Luke, City of London, Mile End Old Town, St. Saviour Southwark, and Newington sanitary areas. Erysipelas showed the highest proportional prevalence in Marylebone, St. Giles, St. Martin-in-the-Fields, Shoreditch, Bethnal Green, and St. George-in-the-East sanitary areas. The eighteen cases of puerperal fever notified during January included 6 in Lambeth, 3 in Islington, and 2 in St. Pancras sanitary areas.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the various sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, Jan. 30th, the deaths of 6224 persons belonging to London were registered, equal to an annual rate of 18·2 per 1000, against 16·5, 19·2, and 17·6 in the three preceding months. The lowest death-rates during January in the various sanitary areas were 10·3 in Stoke Newington, 10·5 in Hampstead, 13·3 in St. James Westminster and in Wandsworth, 13·6 in St. George Hanover-square, and 14·0 in Lee; the highest rates were 22·8 in Rotherhithe, 22·9 in Newington, 24·6 in St. Luke, 24·8 in Clerkenwell, 24·9 in Limehouse, 27·7 in St. Martin-in-the-Fields, and 28·6 in St. George-in-the-East. During the four weeks of January 604 deaths were referred to the principal zymotic diseases in London; of these, 239 resulted from diphtheria, 152 from whooping-cough, 63 from scarlet fever, 57 from diarrhœa, 55 from measles, 36 from enteric fever, 1 from an ill-defined form of continued fever, and 1 from small-pox. These 604 deaths were equal to an annual rate of 1·8 per 1000; among the various sanitary areas the lowest death-rates from these diseases were recorded in Kensington, Fulham, St. James Westminster, Marylebone, City of London, and Lee; and the highest rates in Holborn, Clerkenwell, St. George-in-the-East, Limehouse, Bermondsey, and Rotherhithe. One fatal case of small-pox was registered in London during January, the first that has been recorded in the metropolis for more than six months; this case belonged to Greenwich sanitary area. The 55 deaths referred to measles were little more than a fifth of the corrected average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Westminster, St. George-in-the-East, Limehouse, and Rotherhithe sanitary areas. The 63 fatal cases of scarlet fever were 21 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Chelsea and Shoreditch. The 239 deaths from diphtheria exceeded by 65 the corrected average number; this disease was proportionally most fatal in Shoreditch, St. George-in-the-East, Mile End Old Town, Poplar, Bermondsey, Rotherhithe, Camberwell, and Woolwich sanitary areas. The 152 fatal cases of whooping-cough were just half the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Chelsea, St. Giles, Clerkenwell, St. George-in-the-East, Newington, and Rotherhithe. The 36 deaths referred to enteric fever were 17 below the corrected average number; there was no marked excess of "fever" mortality last month in any of the sanitary areas. The 57 deaths from diarrhœa corresponded with the corrected average number. In conclusion, it may be stated that the mortality in London during January from these principal zymotic diseases was more than 34 per cent. below the average.

Infant mortality in London, measured by the proportion of deaths under one year of age to births registered, was equal to 126 per 1000 during January, and was below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in Westminster, Stoke Newington, Hackney, St. Martin-in-the-Fields, Strand, Lewisham, and Plumstead; and the highest rates in Chelsea, St. Giles, Clerkenwell, St. George-in-the-East, Limehouse, Newington, St. Olave Southwark, and Woolwich.

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR F. J. JENCKEN has received orders to embark on the transport *Dunera* on the 24th inst. He has been posted to the Bombay Presidency. Brigade-Surgeon-Lieutenant-Colonel H. Stokes has received orders to embark on the P. and O. s.s. *Aden* on the 20th inst. He proceeds to the Straits Settlements, when he will take over the appointment of Senior Medical Officer. Surgeon-Lieutenant-Colonel Dorman and Surgeon-Captain G. F. Alexander have been appointed to the Cork District for duty. Surgeon-Captain Fayrer embarks for India this month. Surgeon-Major G. F. Gubbin has been posted to the Medical Charge of the Station Hospital, Gravesend. Surgeon-Captain J. Paterson having reported his arrival at Netley on the 5th inst. is posted to the Surgical Division of the Royal Victoria Hospital. Surgeon-Captain Forrest has embarked for Bombay in the transport *Dilwara*. Surgeon-Major D. O'Sullivan has been placed under orders for service in India.

Surgeon-Lieutenant-Colonel R. G. Thomsett to be Brigade-Surgeon-Lieutenant-Colonel, vice J. Macartney, M.D., retired. The under-mentioned Surgeon-Captains to be Surgeon-Majors:—Michael W. Russell, Benjamin F. Zimmermann, Alexander Stables, M.B., Grenville E. Moffet, M.B., Henry A. Haines, M.D., John D. Moir, M.B., Richard Crofts, George E. Hale, D.S.O., Cecil W. Johnson, M.B., Alfred T. I. Lilly, Charles C. Reilly, Allan Perry, Samuel N. Cardozo, Arthur De C. Scanlan, Henry D. James, and William Turner. The under-mentioned Surgeon-Lieutenants to be Surgeon-Captains:—Harold V. Prynne, Alfred E. Master, M.B., George Dansey-Browning, Ernest S. Clark, M.B., Kennet B. Barnett, M.B., Michael Boyle, M.B., Kenneth M. Cameron, M.B., Charles M. Fleury, Arthur C. Fox, Sebert F. St D. Green, and Walter Tibbits, M.B.—*London Gazette*.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Colonel R. H. Carew, A.M.S., is brought on the Administrative Medical Staff of the Army, vice Surgeon-Colonel Ferguson. Brigade-Surgeon-Lieutenant-Colonel Woodforde Finden, Indian Medical Service, Bengal Establishment, retires from the service. Surgeon-Captain Townsend Wharton Shaw, M.B., Indian Medical Service, Bombay Establishment, resigns the service, subject to Her Majesty's approval. Surgeon-Captain G. B. French is appointed to the Civil Medical Charge of the Naini Tal District, in addition to his military duties, during the absence on leave of Surgeon-Major Tate, A.M.S. Brigade-Surgeon-Lieutenant-Colonel G. F. Bevan, 17th Madras Infantry, is appointed to the Medical Charge of the Regiment, and Surgeon-Captain J. O. Pinto, 21st Madras Pioneers, is also appointed to the Medical Charge of the Regiment. The latest news from Bombay, says the *Pioneer Mail*, reports that Surgeon-Major Dimmock is attacked with the plague. The Queen has approved of the promotion of the following officer of the Indian Medical Service:—To be Brigade-Surgeon-Lieutenant-Colonel: Surgeon-Lieutenant-Colonel George Watters, Bombay Establishment.

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Staff-Surgeons: Arthur S. Nance to the *Collingwood*, and Charles E. Geoghegan to the *Royal Oak*. Surgeons: Robley H. J. Brown to the Royal Marine Depôt at Walmer; William E. Marshall to the *Duke of Wellington*; Sydney H. Youel to the *Penguin*; and Edward Sutton to the *Theseus*. Surgeon and Agent: Patrick J. Flanagan at Mullaghmore.

Hosted by Google

VOLUNTEER CORPS.

Artillery: 1st Dorsetshire (Southern Division) Royal Artillery: David James Lawson, M D., to be Surgeon-Lieutenant. The Highland: Surgeon-Lieutenant J. M. Moir, M.D., to be Surgeon-Captain. *Rifle:* 3rd Volunteer Battalion the Northumberland Fusiliers; William Henry Vickery, gent., to be Surgeon-Lieutenant. 1st Volunteer Battalion the South Staffordshire Regiment: Surgeon-Major H. H. Smith resigns his commission; also is permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement.

HEALTH AND LONG INDIAN SERVICE

In the debate connected with the Army Estimates Mr. Brodrick made a great point of the health of the soldier in relation to long service in India. Lord Roberts and the late General Chesney suggested a system by which the British soldier was to have three years' service for home with a prolongation of nine years for service in India. But Mr. Brodrick appealed to the statistics of the health of the army in India during the closing years of long service. Before the end of the long service 65 per cent. of the army in India were dying. The cost as regards expenditure of life represented the difference between 65 per 1000 and 17 per 1000, the present rate. There were other questions as to efficiency, but Mr. Brodrick mainly relied, in his reply to Sir C. Dilke, upon the results of health statistics as the main factor in his argument against the proposal.

MILITARY WORKS BILL.

The expenditure for barracks and hospitals which has already taken place under the Barrack Loan is very considerable, and that proposed under the Military Works Bill will come to some millions more. That an immense deal has been done towards increasing the accommodation, health, and comfort of the soldier of late years is indisputable. The outlay was sadly wanted, and a good deal still remains to be done in this country and the colonies before our troops are as well housed and provided for as they should be.

ROYAL NAVAL HOSPITAL, STONEHOUSE.

Deputy-Surgeon-General Thomas H. Knott, M.R.C.S., L.S.A., joined the Royal Naval Hospital, Stonehouse, on Jan. 29th for temporary service until the return of Deputy Inspector-General Thomas Browne, M.D., from Bermuda. Deputy Inspector-General Robert May, M.D., M.R.C.S., has ceased duty in the establishment and will proceed on leave prior to his leaving for Bermuda. He has the best wishes of those with whom he has been brought into contact, owing to his uniform kindness to the sick and others.

The s.s. *Spartan* arrived at Southampton on Feb. 4th. She brought twenty-seven invalids for the Royal Victoria Hospital, Netley.

The revised regulations for entry into the Naval Medical Service have just been issued.

ROYAL COMMISSION ON TUBERCULOSIS.—Sittings were held, under the chairmanship of Sir Herbert Maxwell, M P., last week, at 7, Whitehall-place, when the following gentleman were called and gave evidence:—Dr. J. Niven, medical officer of health of Manchester; Mr. W. H. Green, cattle dealer of Higher Broughton, Manchester; Mr. Vacher, medical officer of health for the county of Cheshire; Dr. Newsholme, medical officer of health of Brighton; Dr. Tatham, superintendent of statistics, Registrar-General's Office; Mr. Wiley, of the Butchers' Association, West Hartlepool; and Dr. Gourley, medical officer of health of West Hartlepool. Further sittings of the Commission have been suspended for the present in order to consider the evidence already obtained. It is intended to re-assemble towards the end of March in order to hear the evidence of witnesses appointed by the Royal Agricultural Society, the Scottish Chamber of Agriculture, the British Dairy Farmers' Association, and from the farming interest in Ireland. Further evidence will also be taken from butchers who have complained of the risks to their business arising from want of uniformity of inspection. During the spring certain members of the Commission, including the chairman and secretary, will visit some of the cities on the Continent to inquire into the system adopted for the inspection of meat in public abattoirs, and also into the regulations affecting the sources of the milk and dairy produce exported to this country.

"Audi alteram partem."

PHIMOSIS: A CAUSE OF HIP DISEASE AND TALIPES.

To the Editors of THE LANCET.

SIRS,—In the long review of my book, "Injuries and Diseases of the Genital and Urinary Organs," with which THE LANCET has been good enough to honour me your reviewer states: "On page 164 we are told that numerous evil results may follow phimosis. Among others we find 'simulated or actual hip disease and talipes.' That simulated hip disease may occur we do not question; but we should like very much to know how it is possible for 'actual hip disease' and 'talipes' to result from a narrowed foreskin. If Mr. Morris has met with cases demonstrating the occurrence of such an astonishing result, surely he should bring them forward, and not leave such a statement unsupported by any proofs."

As this criticism seems to require some reply, will you kindly allow me the opportunity of saying that had I been writing a treatise on "hip disease" or "paralytic and spastic deformities," instead of briefly enumerating the immediate and remote effects of congenital phimosis, I should have amplified, by quoting cases and authorities, the statement which has called forth the rebuke of your reviewer. Since Dr. Lewis A. Sayre, during one of his visits to this country nearly twenty years ago, instructed me that congenital phimosis and adherent prepuce was a cause of reflex contractions and paralysis, resulting in talipes and other deformities, I have been in the habit of looking to the prepuce of children complaining of pain in the joints, or affected with lameness, and feebleness of the spine and lower limbs. I have long been convinced myself, and for years have taught, that the disturbance of the nervous centres, the nervous irritation, from genital excitement due to phimosis, produces sometimes spastic contractions, sometimes weakness and partial paralysis, which result in talipes, bent knees, and flexed and adducted hips, and that recovery from these deformities quickly follows circumcision. I am also persuaded that the clumsy walking, the frequent falls, and the frequent adoption of a position of extreme abduction in squatting and straining at micturition, induce actual synovial disease of the hip-joint.

In spite of the teaching of Dr. Sayre, of the details of cases and the figures of some of his patients published in 1876 in his book on "Orthopædic Surgery and Diseases of the Joints," and notwithstanding Dr. Campbell Black's references made in his book on "Functional Diseases of the Renal, Urinary, and Reproductive Organs" and by some other writers, the *rôle* played by phimosis in the causation of disease would seem to be to-day, as Dr. Sayre twenty years ago said it was then, "almost entirely overlooked by the profession in general." Otherwise it would be hardly likely that my statement would have caused astonishment in one so well informed as a reviewer of works on surgery should be. Twenty years ago phimosis was scarcely recognised, except by the few, as a cause of rupture; and even to-day many seem incredulous that an adherent contracted prepuce can lead to changes in the bladder, ureters, and kidneys as extreme as the most persistent narrow stricture of the urethra or an enlarged prostate.

Will you allow me to add to these few remarks that I trust I am duly humbled by the little lecture your reviewer gives me anent his discovery of my mis-spelling of two words; "ileum" for "ilium," and *vice versâ*, is, however, a slip which occasionally occurs in the writings of many excellent authors. The readiness with which the "e" is mistaken by the type-setter for an "i," and the ease with which the proof-reader's eye misses the error in type when his mind is intent on the construction and meaning, explain this error. In my case it is none the less inexcusable because it does not occur in the text, but in the description of a diagram (and to my sorrow, I must add, in the index of illustrations also). But "phymosis" is etymologically unpardonable, especially as it is said to be so spelt "at least twice." I have looked through the chapter on Congenital Defects and Malformations of the Penis and find that the word phimosis (or phimotic) occurs therein fourteen times, but in each instance it is spelt correctly. I

Hosted by Google

have not yet found where the mis-spelling of this word occurs, but I am satisfied it exists, and I thank the reviewer for drawing my attention to such a fault, "which should have had no place" in the book.

I am, Sirs, yours faithfully,

Feb. 9th, 1897. HENRY MORRIS.

"DR. R. R. RENTOUL AND THE MIDWIVES BILL."

To the Editors of THE LANCET.

SIRS,—Dr. Rentoul has been good enough to notice two of the "assertions" contained in my letter published in THE LANCET of Jan. 23rd, a letter which, as he remarks, "gives the lie direct to some of the statements" in his address.

I will take the second first. It is that which deals with Dr. Rentoul's misquotation from Dr. Matthews Duncan's works. He has had the audacity to repeat the misquotation and even to give a reference to the work itself. He says that Dr. Matthews Duncan's tables show that one in fifteen mothers died in their first confinements. The numbers actually given are one in seventy-four.[1] The table Dr. Rentoul appears to have quoted from, it is expressly stated, "will not give results or percentages representing actual values, but only figures for mutual comparison." I pointed this out in my evidence before the Select Committee of the House of Commons, and have done so several times since then. Dr. Rentoul further quotes a single clause from one of the 1890 Bills in order to prove that registration of midwives was no less than an attempt to oblige "the wives of the poorer and wage-paid classes" to "have no one to help them during their confinements but midwives," and although this misconception was pointed out at the time, though the object of the proposed legislation has been repeatedly pointed out since then, and though the whole subject was fully ventilated before the Select Committee, yet Dr. Rentoul still continues to make this preposterous assertion. He neglects to observe that the clause is one which *limits* the practice of a midwife, and he attributes to it an intention to give her for the first time rights which she already possesses. Because of two clumsy expressions in a Bill of 1890 all subsequent measures of the same description are assumed to be directed towards effecting a change in the present condition of affairs, not only exactly the opposite to that which is their expressed intention, but also to give a free hand to midwives in a direction in which they have absolutely no limitation at the present time. In his letter Dr. Rentoul dramatically remarks, "If my case is based on untruths, let it deservedly perish." He has pronounced his own sentence. He leaves me nothing to add to it.—I am, Sirs, yours faithfully,

ROWLAND HUMPHREYS, L.R.C.P. Lond.,
Honorary Secretary, Midwives Bill Committee.

Buckingham-street, Strand, W.C., Feb. 9th, 1897.

THE ARMY MEDICAL DEPARTMENT.

To the Editors of THE LANCET.

SIRS,—Will you allow me to make one or two short observations on the text of Surgeon-Major-General Jameson's admirable address at Netley? The Director-General complains of want of loyalty in the department; but what attempt is there ever made to create and foster that indispensable quality—to promote the content which is essential to solidarity? The Army Medical Staff is made up of isolated units. It is a wheel, so to speak, without a hub, so no wonder it wobbles! The members have no central meeting place (for Netley is so remote), no museum or Valhalla, and, worst of all, no journal, archives, or organ of any description. Surgeon-Major-General Jameson lays stress on the need for professional merit. We cannot do without the "good doctor" to attend the sick and wounded and to prevent disease. Quite so; although it is to be feared that when he invented that catchword Sir Redvers Buller was not thinking of the latter duty, which is far and away the most important. Professional merit is no doubt the chief desideratum; but what is there done to ensure it? Nothing—absolutely nothing. If a medical officer wishes to become professionally meritorious he has to seek for knowledge as best he may from books and records. He is not afforded the smallest assistance or encouragement by the authorities. The medical officers of our army have unrivalled opportunities for acquiring information regarding disease and its prevention in all quarters of the world, but for lack of a little judicious fostering all this valuable material is ultimately wasted. The fruits of experience are allowed to perish ungarnered. Are there not papers published with the annual report, someone may inquire? Yes, the appendix for 1895 contains sixteen papers, of which thirteen emanate from Netley—a mere drop in the ocean, and, I venture to think, by no means the best drop.

In this connexion I may perhaps be allowed to refer to a personal incident. A manual of hygiene for soldiers in India having been called for and a prize of £50 offered for the best no fewer than thirty-four MSS. were sent in. All, without exception, were pronounced unsuitable because they contained theories. One MS., at least, was returned to its author with facetious comments pencilled on the margin. As the Director-General very happily puts it, medical officers share every risk *plus* those belonging to his profession. Man is a combative animal and it is useless to deny that he takes pleasure in fighting; if he does not he is no man. In savage warfare the surgeon is debarred from this pleasure. His eyes are glued to his wounded; he cannot even tell how the day is faring, and ere this has been speared through the back in consequence. To refuse military privileges in full to medical officers is the outcome of sheer intolerance, but unhappily the intolerants are all-powerful at present. It is for the medical men to unite and insist on justice.

Surgeon-Major-General Jameson thinks that officers of the Army Medical Staff, "and particularly the retired ones," are great offenders in the matter of anonymous complaints, but here I trust he is misinformed. One or two individuals with an undue sense of their own merits and importance can perpetrate a great deal of anonymous complaining. Dealing with general matters I should have preferred myself to remain anonymous, but under the circumstances feel bound to sign my name.—I am, Sirs, yours faithfully,

H. R. GREENE,
Brigade-Surgeon-Lieutenant-Colonel (Retired).

St. John's, Woking, Feb. 6th, 1897.

P.S.—I hate appending that ridiculous title, but it is the only one I have a right to. Perhaps Director-General Jameson can see his way to have it changed? If so he will earn my undying gratitude.

HOSPITAL REFORM ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—I venture to think that the following resolution, which was passed at an influential meeting of the medical profession held in London on April 27th, 1871, with the late Sir William Fergusson as chairman, is worth reproducing at the present time:—

"In order to improve the clinical teaching of the out-patient department of the general and special hospitals it is very desirable that the present unrestricted system of gratuitous relief at these institutions be curtailed partly by the selection of cases possessing special clinical interest and partly by the exclusion of those who on social grounds are not entitled to gratuitous medical advice."

This resolution was proposed by Mr. Timothy Holmes, seconded by the late Dr. Anstie, and carried unanimously.

I am, Sirs, yours faithfully,

Cardiff, Feb. 8th, 1897. T. GARRETT HORDER.

*** We have also received from Mr. Garrett Horder the draft of a memorial to be presented to the Royal College of Physicians of London by the Association.—ED. L.

SHOULD EPILEPTICS MARRY?

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Jan 23rd, p. 260, you quote Dr. Gowers' statement on the subject of the advisability of the marriage of an epileptic: "In cases which are the result of accidental lesion of the brain, which are characterised by ..... the absence of hereditary taint, fears of inheritance are groundless." Has Dr. Gowers any special reason for supposing that accidental lesions of the brain are less liable to be transmitted than similar lesions of the eye or the finger, instances of which are so frequently brought under our notice? It is manifest that a hereditary taint must have a beginning, and it is obvious that the taint is stronger at the

[1] Fecundity, Fertility, Sterility, &c., p. 319.

Hosted by Google

start than when it has passed through several generations; and the son, grandson, great-grandson, &c., claim one-half, one-quarter, one-eighth, &c., share of the original trouble. In a family with a hereditary taint of syphilis or phthisis the danger to the offspring decreases in proportion to the distance from the accidental lesion or "origo mali." Until we have some very cogent reason for believing that epilepsy obeys a totally different law, or that it is never the result of accidental lesions of the brain, in spite of Dr. Gowers' assertion that it is so, a physician should, in my opinion, hesitate to offer any hope of immunity to the progeny of an "accidental" epileptic. I am, Sirs, yours truly,

Jan. 26th, 1897. WILLIAM G. THISTLE.

THE BARIUM WATER OF LLANGAMMARCH WELLS.

To the Editors of THE LANCET.

SIRS,—The use of barium as a therapeutic agent has been lately brought before the profession and attention has been drawn in the columns of THE LANCET[1] to a mineral spring (containing that metal in solution) at Llangammarch Wells, Breconshire. I need only remind your readers that the above spring contains about six and a half grains of barium chloride per gallon, besides chlorides of sodium, calcium, and magnesium. It is claimed that its action is similar to that of digitalis, acting as a tonic to the cardiac muscle, steadying the pulse and increasing its volume. While staying at Llangammarch during the season of 1896 I had a number of cases of cardiac disease under my care; from these I select the following as a type amongst others recommended by Dr. Lauder Brunton for the course of treatment there.

A young man, aged twenty-four years, was first seen by me on July 31st. His previous history was good; he had never suffered from acute rheumatism, but had had scarlet fever when a child. He was always fond of athletics, had rowed a good deal at school, but not much since. In 1895 he was in Switzerland, and thinks he over-exerted himself in climbing. His present trouble was first noticed in February, 1896, when he complained of attacks of palpitation, which were especially marked after ascending stairs and after smoking cigarettes, of which he consumed a considerable number. He used alcohol in moderation. His digestion had not been good. On examination he was found to be a well-built, muscular man. The chest was of a good shape, the apex beat of the heart was not distinctly felt, but percussion of the area of cardiac dulness showed that it was enlarged slightly to the left. Upon auscultation no murmur was audible, but after exertion (as running round the room) a systolic murmur was heard which was conducted outwards. The pulse was sixty per minute, of good volume, but irregular, there being from four to six intermissions per minute. The urine was normal.

The treatment adopted was as follows. He was directed to keep in the fresh air as much as possible, not to climb hills or exert himself in any way. He was strictly dieted and not allowed tobacco or alcohol. He was ordered a glass of barium water thrice daily and barium baths were administered three or four times a week. The latter varied in duration from five to twenty minutes and in temperature from 95° to 85° F. He was also advised to take walks daily up a sloping path about 300 yards in length, having an incline of 1 in 6, stopping every few yards for a rest. With the exception of an attack of indigestion his progress was very steady. I found that while immersed in the bath the pulse fell from four to six beats per minute, while the volume increased. This effect was maintained for some hours afterwards. The gentle exercise on the sloping path did not increase the frequency of the pulse. He soon entirely ceased to have any palpitation, and on Aug. 24th I found that although there was no change in the area of cardiac dulness, yet the pulse was much more regular, that the intermissions had diminished considerably, and that the murmur was not audible even after running up two flights of stairs. On my return to London in October I found my patient still free from palpitation, and he informed me that he had had considerable bicycle riding without experiencing any ill effect.

The above results appear to me to be due chiefly to the rest enjoined and the administration of the barium water. Llangammarch seems to me to be especially well fitted for the treatment of such cases, for, in addition to possessing the barium springs, it is situated in a pleasant valley, has a most invigorating air, and is quiet and free from excursionists.

I am, Sirs, yours faithfully,

W. BLACK JONES, M.D., B.S. Lond., D.P.H.

Jan. 30th, 1897.

[1] THE LANCET, Nov. 24th, Dec. 1st, 1894, and June 4th, 1896.

PROPOSED TESTIMONIAL TO PROFESSOR CAMPBELL BLACK.

To the Editors of THE LANCET.

SIRS,—As a mark of the esteem in which Professor Campbell Black is held by practitioners who sympathise with his views on professional matters, and who are specially indebted to him for his recent candidature for the Direct Representation for Scotland upon the General Medical Council, the following committee of subscribers has been formed with a view to presenting him with a testimonial, which it is proposed should consist of his portrait in oils:—

	£	s.	d.
J. McKim, M.D. Glasg.	5	0	0
Sir Henry Littlejohn, M.D. Edin.	1	1	0
R. Grieve, F.F.P.S. Glasg.	1	0	0
Joseph Bell, M.D. Edin.	1	1	0
J. Maxwell, M.D. Glasg., Tobermory	0	10	0
Jas. Dunlop, M.D. Edin.	1	1	0
J. Erskine, M.B., Glasg...	2	2	0
R. MacNab, M.D. Glasg., Brighton	1	1	0
D. Moffat, M.B. Glasg. ...	0	10	6
G. R. Fortune, L.R.C.P. Edin.	1	1	0
H. Murray, F.F.P.S. Glasg.	1	1	0
J. F. Sutherland, M.D. Edin....	0	10	0
A. MacDonald, L.R.C.P. Edin....	1	1	0
J. F. Stevenson, L.R.C.P. Edin....	1	1	0
D. Cowie, M.B. Glasg. ...	1	1	0
J. C. Woodburn, M.D. Glasg.	1	1	0
Angus Macphee, M.D. Glasg.	1	1	0
W. MacDonald, L.R.C.P. Edin....	0	10	0
G. Yeaman, M.D. Glasg.	1	1	0
J. Provan, M.D. Glasg. ...	1	1	0
D. R. Cameron, L.D.S. F.P.S. Glasg.	1	1	0

Subscriptions have also been received from a number of lay friends. We beg to bring the proposal under the notice of practitioners who may be inclined to support it and shall be glad to receive and acknowledge subscriptions.

We are, Sirs, yours faithfully,

JAMES ERSKINE, M.B. Glasg., 351, Bath-street; D. MACLACHLAN, Solicitor, 33, Renfield-street, } Honorary Secretaries.

D. FORTUNE, J.P., 84, Wilson-street, } Honorary Treasurer.

Glasgow, Feb. 8th, 1897.

LORD LISTER AND HIS FORMER PUPILS.

To the Editors of THE LANCET.

SIRS,—In common with many others I think the elevation of our old and revered teacher, Sir Joseph Lister, Bart., to the Peerage should not be allowed to pass without his former pupils in London, Edinburgh, and Glasgow having an opportunity of showing their appreciation of the honour by giving him a complimentary banquet. No doubt the committee of the Graduates' Testimonial would act also in this matter, and in the meantime I shall be glad to receive the names of those who favour the idea.

I am, Sirs, yours faithfully,

GEORGE ELDER.

17, Regent-street, Nottingham, Feb. 8th, 1897.

HEALTH OF TROOPS IN INDIA.

To the Editors of THE LANCET.

SIRS,—Would you kindly allow me to state in THE LANCET that a lecture will be given, followed by a discussion, at the United Service Institution, on Friday, Feb. 19th, at 3 P.M., on the Result of Abolishing the Contagious Diseases Acts in India and other foreign stations? We shall be glad if gentlemen will attend, especially those of the medical profession, who may have had experience of India.

I am, Sirs, yours faithfully,

Piccadilly, W., Feb. 10th, 1897. R. L. DASHWOOD.

"THE SANITARY STATE OF THE ARMY IN INDIA."

To the Editors of THE LANCET.

SIRS,—It is to be hoped that your leading article in THE LANCET of Jan. 30th on the spread of syphilis in the Indian

Hosted by Google

army may be followed by others couched in even stronger terms. If the facts were fully known there would soon be a loud demand for some measures by which the evil might be diminished. It seems to me that no one has sufficiently considered the effects upon the native population of the spread of syphilitic disease. For many miles, even for several days' journey, round some of the military stations, especially in the hills, syphilis is very prevalent, and its effects upon the population are too evident. The infection is conveyed partly by soldiers, both European and native, visiting the native villages, and partly by men and women who come from the country round with supplies for the bazaars, who contract the disease and carry it to their homes. Medical aid for these unfortunates there is none or next to none. Those who have no regard for the health of soldiers may perhaps feel some pity for the unhappy women and children of far-off villages. Many of the people in England who have helped to bring about this state of things know little of the course of syphilitic disease or how the innocent suffer for the sins of others. I may say that there was no objection amongst the native population to the measures taken to check the disease and to cure those suffering from it: This might easily be verified if an inquiry were made through the district magistrates.

I am, Sirs, your obedient servant,

Feb. 8th, 1897. BRIGADE-SURGEON.

ELECTIONS OF MEDICAL OFFICERS OF HEALTH: A PROTEST.

To the Editors of THE LANCET.

SIRS,—A short time ago I applied for an appointment as medical officer of health for a rural sanitary district. The medical officer who resigned the appointment is county medical officer of health, and holds the office of medical officer of health for nearly all the sanitary districts in the county, his salary amounting to about £1000. The advertisement announcing the vacancy stated that canvassing, directly or indirectly, would be deemed a disqualification. I went over and inquired of the assistant clerk (in the absence of the clerk, with whom I made an appointment) if the appointment would be an open one and if any local man was likely to apply. I was assured that the appointment would be a perfectly open one and that the medical officer of health had ceased to have any connexion with the district. He, in fact, lives as far off the district as I do. On the strength of this information I got my testimonials and application specially printed. After the lapse of a few days I was informed that I was one of two selected candidates and was asked to attend the meeting at which the election would be made. I duly attended and found there were only four members present (not a quorum, I understand) and my opponent. You may imagine my surprise and disgust when I found in my opponent a young man with the D.P.H. Cambridge and B.Sc. of Edinburgh, who had been acting for fifteen months as assistant without salary to the medical officer of health who had just resigned. I expressed my surprise that he should go in for such a small appointment (the salary is £75). He said that he would not have done so but that he could continue to act as he had done hitherto as unpaid assistant to the medical officer of health who had given up this district. No D.P.H. was necessary, and as I had attended during the past year courses of instruction in hygiene, bacteriology, and public health chemistry I imagined I should stand a good chance for such an appointment when I could practise generally at the same time.

Now, I ask you if it is likely that no influence was used in favour of the successful candidate, and if it is a desirable state of things that a medical officer of health should in this way pay his assistant? General practitioners, when they require assistance, pay for it out of their own pockets, and why should medical officers of health with larger incomes than the average general practitioner not do likewise? In this case the county medical officer of health will hold this appointment through his assistant, who will receive the salary in return for his services, as but for the influence of the county medical officer of health the assistant would not have obtained it. Then the assistant will hold it only long enough to enable him to get a larger plum in the public health service when the ratepayers will be required to go to the expense of another advertisement and second-class railway fare for the successful and unsuccessful but selected candidates. This is evidently against the interests of the ratepayer. The vacancy created would, of course, be again filled by another assistant, and so the appointment would become really vested in the appointment of assistant to the county officer.

Then, again, I consider it nothing but an insult to have asked me to attend the meeting at all, and my presence was required only to throw dust in the eyes of the public and give the affair an appearance of impartiality which I am perfectly confident it did not possess. I protested against the appointment by letter and sent an account of the affair, with a copy of my protest, to the Local Government Board, calling their attention to the relationship existing between the ex-medical officer of health and the successful candidate. It is unjust to me because I incurred expense, which I should not have done had I had the least idea that the assistant of the county medical officer of health would be a candidate. It will, if allowed to go on, be a trap for others, as without a doubt it will be advertised sooner or later as vacant, and aspirants for the office will be misled by the terms of the advertisement, which stated that "no canvassing directly or indirectly" would be allowed and that "second-class railway fare will be given to selected candidates." I beg to enclose my card. Trusting you will find space for this letter in your valuable journal, I am, Sirs, yours truly,

Feb. 8th, 1897. JUSTITIA.

"A CONFERENCE OF GENERAL PRACTITIONERS."

To the Editors of THE LANCET.

SIRS,—In reference to Mr. Brocklehurst's letter in THE LANCET of Jan. 30th, wherein he suggests a conference to consider the best means whereby the grievances affecting the profession can be remedied, permit me to say that, contrary to the editorial note appended to his letter, I believe his views would meet with no half-hearted response. We shall very soon have to decisively face this friendly society or club question. Our grievances are now becoming alarmingly widespread. At Beckenham, Penge, and Anerley (S.E.) the request of the medical men for a living wage and a voice on the medical matters affecting the clubs and benefit societies and that vexed question of wage limit have been characterised as dictatorial, inquisitorial, &c.; and we are plainly told that any further requests of the medical men will result in the withdrawal of all the clubs in the district and the establishment of a United Friendly Society's Institution officered by a couple of medical men of ability imported from a distance. We are further informed of a registry in the North of England where M.D.'s Lond. and F.R.C.S.'s are eager for these appointments, to say nothing of scores of Scotch, Irish, and London Licentiates. Now, Sirs, London has been fortunately free from these institutions up to now, but should they start and multiply it will be a matter calling for the serious consideration of the profession, in the metropolis especially, in view of the fact that our profession is so congested. The fact is we are up to now hopelessly beaten on this club question; in spite of the magnificent work accomplished by your Commissioner, and in spite of the prognostications of many of your contemporaries, institutions like Derby, Lincoln, Yarmouth, &c., are flourishing, to the chagrin and mortification of the medical men of those towns. A general conference may suggest the means for combating these difficulties. It is strange, yet true, that whenever professional men for their own interests combine to secure a living wage, thereby propounding some of the trades' union theories, their actions are at once regarded as malignantly aggressive by the very men who are everlastingly howling about these doctrines. The one main cause is that the supply is so much in excess of the demand, and if the deans of our schools would be honest with intending students in telling them that the outlook for a qualified man without means is about on a par with that of a night-soil man or bricklayers' labourer it would tend to minimise the evil. For the truth of this statement *vide* THE LANCET of Jan. 30th, where qualified men are sought for £1 a week.

I am, Sirs, yours obediently,

Feb. 5th, 1897. SCOTUS.

"ARMY EXAMINATIONS."

To the Editors of THE LANCET.

SIRS,—"Physician" concedes every point raised in your annotation, but he is in error in ascribing to THE LANCET

Hosted by Google

conclusions which were contained in quoted matter. His admission that "the competition necessitates a special preparation which is carried out under disadvantages at school, but with more success outside by special army instructors" goes to the root of the matter. A system of competition that necessitates the premature withdrawal of boys from school and has consequently led to the evolution of the crammer cannot be defended without decrying public school life. If crammers are good schools must be bad, and *vice versâ*.

I am, Sirs, yours faithfully,

Feb. 6th, 1897. UNCRAMMED.

HOSPITAL ABUSE.

(BY OUR SPECIAL COMMISSIONER.)

VI.—LEEDS *(concluded)*.[1]

The Work-people's Hospital Fund and its Tendency to Convert the Infirmary into a Provident Club.—The Claims and Grievances of the Workmen Subscribers.—The Jews at the Infirmary.—The Leeds Public Dispensary.

FROM the statements recorded in our last issue it will have been seen that the existence of hospital abuse at the Leeds Infirmary cannot be denied. Indeed, it has formed the subject of many discussions among the members of the staff and the managing board. At a special meeting held at the Leeds Infirmary on this particular subject very diverse opinions were expressed; but the great bone of contention, however, was the amount of authority, if any, which the working men subscribers ought to exercise. In this respect the position at Leeds is very remarkable and may bring about a complete revolution in the purpose and organisation of the infirmary. It has already been seen at Liverpool and elsewhere that the mere fact of throwing a few pence into the collection box on Hospital Saturday or Sunday has led many of the poorer classes to infer that they thus acquired a right to go to the hospital. In different towns several general practitioners have expressed their conviction that the Hospital Sunday Fund had done them a great deal of harm. They had lost patients who now went to the hospital because they subscribed to that fund. But at Leeds the position is much more serious because the subscription does not consist of a chance dole given once a year, and perhaps not every year, but of a systematic weekly levy duly deducted from workmen's wages. When the "Leeds Workpeople's Hospital Fund" was first started its originators certainly did not foresee the very serious consequences that might accrue. This fund was established in 1887. At that time £1800 were collected from the working classes by voluntary subscriptions and without any sort of organisation. Now Leeds is divided up into twenty wards or districts. Every year a public meeting is held in each district, and a chairman, an honorary secretary, and a committee are elected to represent the district and to organise the collection of money from the working classes of that district. Each district committee selects two of their own members to form an executive in conjunction with a similar representation from all the other districts. The General Committee, composed of all officials from all districts, meets once a quarter, and consists of some 600 members. Thus a regular parliament of a thoroughly representative character has been established by the working people of Leeds outside the infirmary and yet destined to deal with and, in a measure, to control the infirmary. Nor is it easy to resist such interference, for the workmen will soon be contributing about a third of the total expenditure of the infirmary. It is true that the income for 1895 amounted to £33,798, but this includes exceptional legacies to the amount of £11,279. The total income in 1893, including legacies, was only £22,263. The total expenditure in that year was £24,897, so there was a deficit. In 1895 the expenditure was £24,122. I was not able to ascertain what the total expenditure for 1896 would be, but I was assured that the workpeople's fund would in round numbers reach the figure of £7000. The average annual expenditure for the five years, from 1891 to 1895 inclusive, was £23,179. Thus it will be seen that the workmen's fund exceeds a quarter of that amount, and as it is likely to increase it will probably be soon equal to a third of the total expenditure. But the workmen not only contribute money, they also devote an immense amount of time and labour. To collect £7000 for the most part in penny contributions implies a great deal of organising work, of book-keeping, &c. Even when larger sums are obtained the work is equally onerous. These larger sums are secured by the holding of bazaars, the giving of concerts, or the organisation of working-men's gala festivals. To make such festivals a success generally requires four months' hard preparatory work.

A great number of workmen belong to these organisation committees. They subscribe out of their wages to the hospital fund and, what is more valuable, devote a great portion of their leisure time to the business of organisation. At the same time, many belong to benefit clubs to which they also subscribe. It sometimes happens, however, that they are not satisfied with the treatment they receive from their club medical officer, and they consider that, as they have rendered so much service to the infirmary, they are justified in asking for a consultation for a second opinion from some member of the hospital staff; but, just because they have worked so constantly for the infirmary, these committee men are known, and, therefore, are told that they must go back to their club medical officer and that they are in too good a position to claim advice at the hospital. At the same time, there are thousands of patients admitted who are as well off and better off than themselves, but who are not so well known. This is more particularly the case with regard to the very large number of patients who do not live in Leeds, but who are attracted to Leeds by the very high reputation the infirmary enjoys. The Yorkshire workman is animated by a rugged sense of independence. He does not want charity, but why should he pay, and this in a regular and systematic manner, for an infirmary that refuses to give him help while it freely assists other workmen who pay nothing at all, but who happen to live outside Leeds? The workmen of Leeds pay nearly a third of the cost of the infirmary, and this gives them no right to claim admission when ill, but the workmen outside Leeds, who do not raise a finger to help the institution, are freely admitted. There is no denying the injustice of such a state of affairs. The more a workman does to raise funds to help the infirmary the smaller are his prospects of ever receiving any benefit from the infirmary.

Apart from this grievance, which applies to the well-known members of the committees of the workpeople's fund, there is the question of the general crowd of subscribers who are not personally known, and are therefore not often detected when they apply for medical advice at the infirmary. Many, however, do not conceal the fact. On the contrary, they often boast that they are subscribers, being under the impression that this entitles them to a good reception and to every care. Formerly the infirmary was maintained exclusively by subscriptions given by the rich alone for the benefit of the poor. Now the poor—or, in any case, the comparatively poor—subscribe a very large proportion of the funds needed, and they naturally think that they have a claim on the institution. This must necessarily tend to transform the infirmary into a sort of medical benefit club; yet the proposal to convert the infirmary into a huge provident club would at the present moment be met by the immediate resignation of the entire medical staff. But then the whole of the visiting staff works gratuitously so as to assist the poor. The infirmary might, however, be divided into two. Certain hours of consultation and a portion of the wards might be devoted exclusively to charitable purposes. The remaining time and space could be given to subscribers and for this portion of the work the entire medical staff would be paid. The full payment of the medical staff would very materially change the aspect of the question. A large section of the working class are thoroughly convinced that nowhere can better medical advice be obtained. It is a common saying that "You will be all right if you can get into the infirmary," therefore the working classes are willing to pay liberally and regularly so as to acquire the right of

[1] The previous articles on this subject were published in THE LANCET on the following dates: (1) Sept. 26th, 1896, Plymouth and Devonport; (2) Oct. 10th, 1896, Exeter; (2 *continued*) Oct. 17th, 1896, Exeter; (3) Oct. 31st, 1896, St. Thomas's Hospital, London; (4) Nov. 14th, 1896, Liverpool; (4 *continued*) Nov. 21st, 1896, Liverpool; (4 *continued*) Dec. 12th, 1896, Liverpool; (5) Jan. 2nd, 1897, Manchester; (5 *continued*) Jan. 9th, 1897, Manchester; (5 *concluded*) Jan. 23rd, 1897, Manchester; and (6) Feb. 6th, 1897, Leeds.

Hosted by Google

going to the infirmary when they are ill. It is not much use saying that it was never intended to give them any such right. The working men are well organised. They have been taught and educated from their childhood that it was their duty to subscribe regularly to certain institutions. They subscribe to their trade union, to a benefit club, perhaps to a Christmas or goose club, perhaps also to a building society or a football club. In exchange for these subscriptions they receive solid benefits. Now and for some years an ever-increasing number of workmen have been induced to subscribe with equal regularity to the Leeds Infirmary. Certainly it has been stated here and there that in exchange for this last sacrifice they are to receive no advantage whatsoever, but such an assertion is so utterly at variance with the whole trend of their life and experience that naturally it is neither understood nor accepted. Then, again, the working classes have acquired the art and principles of self-government. The man who pays votes and the man who votes governs. Every subscriber to the Workpeople's Hospital Fund votes, and therefore this democracy not only decides how this fund shall be employed, but will not allow any interference on the part of outsiders. When the management of the infirmary has attempted to interfere with the action of the workmen's committees they have been very promptly and sharply told to mind their own business. Here, then, we have a new force consisting of money and of men, which in course of time may entirely revolutionise the hospitals of more than one town. Indeed, this revolution has already commenced—at least, at Leeds. The workmen are not satisfied with the management of the convalescent home attached to the Leeds Infirmary. Consequently the executive of the Leeds Workpeople's Hospital Fund adopted at a recent meeting the following resolutions:—

"That some building suitable for a convalescent home be rented on a lease of three or five years (with option of purchase) capable of accommodating from twenty-five to thirty patients. That preference be given to a building in a salubrious district some miles distant from Leeds and possessing adjoining land. That the rent and cost of furnishing and maintaining the home be provided out of the Workpeople's Fund. That such cost be deducted from the fund before any division is made for the medical charities. That applications for admission to the home be confined to workpeople who subscribe to the fund. That all applications for admission to the home be made to the ward president or secretary, who shall bring the same (with full information) before the committee appointed to deal with such applications. That the period of residence for each patient be limited to two weeks—unless the patient is in such a state of health that removal would be injurious. That the cost of conveyance of patients from and to Leeds be defrayed by the committee, when satisfactory evidence is produced as to inability to pay on the part of the patients. That a salaried medical officer be appointed to the home."

In the face of such a resolution who shall say but that what has actually happened with regard to the convalescent home may not also occur with regard to some wards or sections of the infirmary? It may be said that this would never be sanctioned at the infirmary; but can the managers of the infirmary prevent the construction of some other hospital? Leeds is an exceptionally favoured position, because the infirmary is free from the competition of rival hospitals. But this cannot continue for long. The infirmary, it has already been stated, has grown and grown till now it has reached the furthermost limits of possible extension. On the other hand, the population of the town is for ever increasing. The necessity of more accommodation, which will soon arise, may be met by the workmen withdrawing their subscriptions from the infirmary and utilising them to maintain a hospital of their own. According to the last printed report the total average cost of in-patients at the infirmary was £1 1*s* 8¼*d*. per week, and the cost of out-patients 1*s* 3¾*d*. In the face of these figures the workmen subscribers justly maintain that they do not receive from the infirmary anything like an equivalent for what they give to the infirmary. Nor can they agree to the theory that what they subscribe is a charitable gift for which they must expect no return. Such a theory might be accepted even by the working men subscribers if there existed no abuse at the infirmary. But it is notorious, obvious, and undeniable that workmen who do not subscribe at all, yet who are as well off as, and sometimes better off than, those who do subscribe, are readily admitted into the infirmary. This, as already explained, is more particularly the case with regard to workmen who live outside Leeds. Workmen might be willing to subscribe to help those poorer than themselves, but why should they give their money for the medical treatment of those who are as well off as, and better off than, themselves? While such abuses continue the workmen cannot look upon the infirmary as a pure charity. If the hospital authorities choose to spend the money they receive from the middle and upper classes on workpeople who could, but do not, subscribe, surely they should spend the money they receive from workmen on such workmen who are inspired by a higher sense of duty and therefore contribute, and contribute largely, towards the expenses of the infirmary. Thus the authorities are face to face with this dilemma. Abuse must be absolutely prevented and no one received at the infirmary except the extreme poor, or else workmen subscribing to the Hospital Fund must be acknowledged as having purchased by their subscription a right of entry to the infirmary.

Of course, the difficulty is met for the moment by a sort of compromise. It is denied that the workmen subscribers to the workpeople's hospital fund have acquired the right to be treated at the infirmary; but, in practice, they are very largely admitted to such treatment. It is not, however, to be expected that such a makeshift arrangement will last indefinitely. The workmen will ultimately rebel against such a loose proceeding. They will stand on their dignity and demand admittance to the hospital as a right, or else that the workmen who do not subscribe to the hospital fund must likewise be excluded. It is impossible to expect that subscribers will long consent to have no better standing than men of their own class who do not subscribe.

At present when a patient arrives at the infirmary he has first of all to see a clerk, who takes his name and address. If the clerk finds that the applicant is living in a house where the rent is likely to be 5*s*. or 6*s*. or more per week he asks for further information, inquires where he is working and what wages he earns. Then, if he is not satisfied, the applicant is referred to the head clerk. In the majority of cases it will be found that these comparatively well-to-do applicants have already run up a big "doctor's bill," which they are endeavouring to pay off by weekly instalments, and in such cases they are admitted to the infirmary. Others belong to a benefit club; but as there are clubs where the payment is as low as 2*s*. and 2*s*. 6*d*. a year the medical attendance obtained for this sum is of a very inferior character. Others may be in receipt of good wages but have very large families. In all such cases they may even obtain gratuitously from the infirmary certificates that enable them to claim sick allowance from their clubs. It is difficult to send an applicant back to his club medical officer when it is found that he is also a regular subscriber to the infirmary. Others frankly admit that they could pay for a private medical man, but have greater faith in the infirmary medical officers, and therefore work hard for the workpeople's hospital fund and themselves subscribe regularly, and trust that this will entitle them when ill to receive advice from the infirmary. The head clerk admitted to me that it was very difficult indeed to send away such persons. Even the poor Jews from the sweating dens that abound in Leeds are liberally subscribing to the infirmary. Much has been done to respect their religious principles. Thus no necropsies are allowed on the bodies of Jews unless there is an absolute necessity, and then all the parts are very carefully collected for burial. The Jews are also allowed to bring their Kosher food. The Jewish community offered to provide at their own expense a Jewish cook for the infirmary, but to prevent this complication they are now allowed to provide their own food from the outside. They have proved themselves to be very grateful people and express their satisfaction in a most feeling manner.

About three years ago the Charity Organisation Society was asked to depute one of its members to investigate cases of abuse. A certain number of applicants were then visited in their own homes. Very few cases of abuse were found, and those who seemed fairly well situated were members of the artisan class who subscribed to the workpeople's hospital fund. This system of inquiry was only maintained for three months and many persons who abuse the charity kept away during that time. Even when cases are investigated there is generally a divergence of opinion on the board of management as to what constitutes an abuse. One section maintains that some of the cases do constitute an abuse; the other section that there is no abuse, or that the abuse is not sufficiently flagrant to warrant any interference. But how can the board agree as to what is an abuse or not when one section believes that workmen subscribers have no rights, another section that they have every right, and a third that they do not get their money's worth? The only really strict surveillance exercised is with regard to admissions to the

Hosted by Google

convalescent home. For the last fifteen or sixteen years all such cases have been referred to the Charity Organisation Society and a strict investigation has been made. As a result we have seen that the workmen are going to establish a convalescent home of their own.

There is one important medical charity at Leeds against which I heard no complaints. This is the Public Dispensary in New Briggate. During the twelve months commencing on July 1st, 1895, and ending June 30th, 1896, a total of 31,368 patients were attended there. The secretary, Mr. Teale, explained that when first appointed he understood his principal duty was to prevent abuse. The patients are not required to bring any recommendation. The secretary carefully questions each applicant, taking down his or her name, age, address, occupation, and wages. The address more especially is a good indication as to the patient's means. There is a rule according to which the secretary must visit their own homes at least five out of every 100 applicants. Nevertheless, he now rarely finds cases of abuse, nor has it as yet been necessary to call upon employers to check the statements made as to the wages received. It is so well known that these inquiries are made that none but the poor venture to attend. It is very rare to find an applicant paying more than 5*s*. a week for rent. Mr. Teale did, however, last November ascertain that a patient paid £19 a year rent, but then he had three lodgers. Another case was that of a man with one child who earned £1 per week, but lived with his mother, who kept a public-house. Some applicants at once declare that they can afford to pay and only attended because they did not know what medical man they should consult. Others attend who are members of clubs and say that the club medical man has done them no good. Another case of abuse recently detected and stopped was that of a boy whose father employed eight workmen. When Mr. Teale entered upon his duties some three years ago he had to stop many more applicants. Thus during the first six months he discovered sixty-seven cases of abuse, but during the last six months he has only detected eighteen cases of abuse.

The great question at Leeds, then, is whether the infirmary could and should be managed on somewhat similar lines to the public dispensary. The opinion is growing fast that the infirmary is becoming less and less a charity. The Board accept the money they receive as charitable gifts and do not admit that it confers any right on the donor. The sole claim to the infirmary should be poverty. That is the creed; but in practice this theory is not observed. The management and the medical staff have tolerated so many abuses that people are beginning to laugh at this theory, and the workmen dominate more and more public opinion. The position is certainly most embarrassing, peculiar, and pregnant with the potentialities of great changes. It is a striking example of the difficulties that arise from the toleration of hospital abuse.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Royal Infirmary.

THE annual meeting of the trustees of the Liverpool Royal Infirmary was held on Jan. 30th, under the presidency of Mr. William Rathbone. The treasurer's report, which was an encouraging one, showed that the financial position had improved. Some considerable legacies and donations came in during 1896, but were almost all for endowment. At the present low rate of interest for trust securities they add comparatively little to the current income of the charity. The maintenance fund, however, has not been drawn upon during the year, which is thereby so much strengthened for the future. Altogether the infirmary had dealt with £29,250; the ordinary income, including the Hospital Sunday and Saturday contributions, being £10,629, and the expenditure £13,659. The sum of £6500 had been invested, of which £5000 had been received from Mr. Tate, whilst £3632 had been received from land sold to University College. Much to the regret of all connected with the Infirmary, Dr. Alexander Davidson has resigned the office of honorary physician which he has held for twenty years; and likewise Mr. Hamilton B. Gilmour has resigned the chairmanship, after nineteen years' occupancy of the post, which he filled with much dignity. Both gentlemen will retain their connexion with the Infirmary, inasmuch as Dr. Davidson was elected an honorary consulting physician, and Mr. H. B. Gilmour is to be the President for the ensuing year. For the vacancy caused by the retirement of Dr. Alexander Davidson the candidates, as far as is at present known, are Dr. T. R. Bradshaw, the senior assistant physician; Dr. J. Hill Abram, the junior assistant physician; and Dr. James Barr, physician to the Northern Hospital. The appointment is in the hands of an electoral committee consisting of about ninety-five members.

Liverpool Infirmary for Children.

The forty-fifth annual report just issued gives the number of in-patients treated during the year 1896 as 1076 and the number of out-patients as 13,832, these figures showing decreases of 89 and 324 respectively as compared with those of the previous year. The out-patient department had again been very busy and had heavily taxed the energies of the staff. Special attention had been given by the honorary medical officers to eliminate trivial and other improper cases, and, but for this precaution, the figures would undoubtedly have been larger. The funds of the institution, which had reached a low ebb, were fortunately greatly assisted by donations of £200 in memory of the late Mr. George Holt from Mrs. and Miss Holt, of £108 from Lord Derby, and £50 from the R. P. Houston Fund, raising the total income to within £30 of the expenditure, so that the balance due to the treasurer was now reduced by the sum of £26 12*s*. All the legacies—£570—had been spent. Mr. James Lister sent a donation of £50 in view of the out-patients' requirements, and within a few days of the close of the year Mr. J. Marke Wood generously contributed the sum of £1000 without conditions. The amount apportioned by the Hospital Sunday and Saturday Fund was £660. Mr. John Grant Morris re-furnished one ward with eighteen cots. This is one of the charities which was severely criticised by THE LANCET Special Commissioner in his recent investigations in Liverpool on "Hospital Abuse." It is quite true that young general practitioners bitterly assert that patients are constantly taken by their parents to this hospital for "special advice" and that the said parents used to and could still afford to pay moderate fees. It is only just to say that the fault does not rest with the medical staff, who are all anxious to prevent abuse at the hospital; yet the fact remains that the Children's Infirmary is not a popular institution with the young practitioners of Liverpool.

Bequests to Liverpool Charities.

Under the will of the late Mrs. Elizabeth Buckton of Walton the Liverpool Stanley Hospital, the Ladies' Charity and Lying-in Hospital, the Liverpool Infirmary for Children, and the training ship *Indefatigable* will each benefit to the extent of £50, and the Liverpool Society for the Prevention of Cruelty to Children to the extent of £20.

The Lunacy Fee Dispute in the Prescot Union.

Dr. Hall of Prescot, in declining to accept the reduced fee for certifying pauper lunatics for removal to asylums, carried by a small majority by the board of guardians, deserved the sympathy and support of his brother practitioners, which, it is gratifying to find, has been accorded to him. The clerk reported to the board that since the last meeting a lunatic had been removed to the county asylum at Rainhill, and Mr. James Mercer, the magistrate who signed the order, had appended a note stating that he authorised the payment of the usual fee of one guinea, his intention being to avoid any possible delay that might arise in consequence of the demand by the medical men as shown in the letters that were laid before the meeting. Mr. Mercer also stated that he had done this under protest, and trusted that the guardians would take the whole question to the Local Government Board. It is not easily seen how the Local Government Board or the Commissioners in Lunacy can assist the board of guardians in this matter; it is not in the power of those two bodies to compel Dr. Hall or any other medical man to accept half a guinea for this work. They have agreed among themselves not to accept the minor fee, so there is nothing left to the guardians but to pay the guinea fee. The chairman was only making use of superfluous language in saying that "a grave responsibility would rest on Dr. Hall if anything serious happened in the house through his refusal to sign the certificate for a lunatic to be placed under proper control unless he were paid the guinea fee." Dr. Hall is the

Hosted by Google

best judge of the value of his own services and was quite within his rights in declining to sign the certificate, irrespectively of the urgency of the case, unless he received the fee which he and his medical brethren considered to be the recognised one; and any responsibility attaching to delay in dealing with the patient lay with those who had thought fit to reduce the fee without consideration of the possibility of its rejection by the local medical men. Dr. Hall is entitled to the respect and the thanks of the profession for his attitude under embarrassing circumstances, thanks which are equally due to his brethren for their kindly help.

Insanitary Dwellings.

The fourteenth "presentment" of the Public Health Department was issued last month and included 890 houses. According to the report furnished by Dr. Hope, the medical officer of health, they consist usually of three rooms placed one above another and connected by stairs without any intermediate landing, so that practically the same atmosphere pervades each of the three rooms. The houses, moreover, are back-to-back and side-by-side with others of similar structure, consequently there cannot be either back windows or side windows or through ventilation, neither is there a water-closet provided for each house nor a direct water-supply. The houses are arranged in courts, the entrances to which are narrowed or even converted into tunnels, by the contiguous street houses. The water-supply is by standpipes in the courts and the receptacles for ashes or other refuse are also placed in the courts for the common use of the inhabitants. The water-closets, being outside the dwellings at exposed places in the courts, are difficult of access by night or in bad weather and in times of sickness, from which it results that the people either retain excrement in vessels in the rooms or deposit it anywhere in the court. In some instances the brickwork of the premises is still good, but, on the whole, the property is in a general state of dilapidation and ruin. Some of the courts lead off streets forty feet wide, such as Bispham-street, but this does not lessen the insanitary condition of the court. During the year 1895 no less than 779 notices were issued from the sanitary department to the owners of the property in question to cause the abatement of nuisances such as choked and defective drains, dangerous roofs, and such like. In addition to these notices ninety-eight others were sent during the past twelve months under the Public Health Act to remedy nuisances arising from filth alone. The average death-rate for the whole of the "presented" property during the three years ending 1895 was 42 per 1000, varying in different groups from 30·3 in the Gore-street group up to 79·6 in the Paul-street group. The death-rate for the whole city during the same period was 25·3, and the average for the dwellings in Victoria-square was 22 per 1000. The total population displaced by the demolition of the houses reported upon will be 3272; there is no reason to fear that over-crowding will be caused in other parts of the district, as there are at present 1495 empty houses within a radius of a quarter of a mile to be let at rentals varying from 2*s.* 3*d.* to 6*s.* per week.

WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT.)

Precautions against the Bubonic Plague.

AT the meeting of the Bristol sanitary authority, held on Jan. 28th, Dr. D. S. Davies, the medical officer of health, stated that Dr. Reece, one of the medical inspectors of the Local Government Board, had had an interview with him in regard to the port arrangements for the medical inspection of vessels, and particularly with respect to the possible introduction of plague by vessels from the infected districts in India. It was resolved to recommend to the town council that the Notification Act already in force in the urban district should be formally extended to include the port district.

Vaccination in Bristol.

At the last meeting of the Bristol board of guardians the clerk read the summary from the vaccination officer from Jan. 1st to June 30th, 1896, which showed the total numbers of births to be 726; of this number 493 were successfully vaccinated, 92 died unvaccinated, 10 cases were medically postponed, 2 were removed to places known by the officer, 65 removed to places unknown, leaving on Jan. 31st, 1897, 67 neither entered on the officer's register book nor temporarily accounted for in the report book.

Health of Bristol During the Past Quarter.

During the fourteen weeks ended Jan. 2nd there were 1671 births and 1048 deaths in the city of Bristol. The births corresponded to an annual rate of 27 per 1000. The death-rate was 16·9 per 1000, which was 1·8 below the average. Among the 1048 deaths are included 215 infants under one year and 349 of persons aged upwards of sixty years. The infant deaths were in the proportion of 129 per 1000 births registered during the same period, this rate being 21 per 1000 births lower than the average in the thirty-three large towns, which was 150. The zymotic death-rate was 0·9 per 1000, which was 0·8 below the average. Fifty-seven deaths were due to the principal zymotic diseases—viz., whooping-cough, 25; scarlet fever, 10; diphtheria, 9; diarrhœa, 8; and "fever," 5. Different forms of violence caused 30 deaths.

The Proposed Sanatorium for Bristol.

A meeting was held on Jan. 27th to consider the best way of commemorating in Bristol the length of the Queen's reign, and a committee was formed to prepare a scheme dealing with the erection of a sanatorium in connexion with such local medical charities as may be decided on. It is satisfactory to see that there is every prospect of a sanatorium being erected in Bristol or the immediate neighbourhood. It is hoped that £40,000 will be raised, half of which will be required for the endowment fund.

The Devonport Board of Guardians and Fees for the Certifying of Lunatics.

At the meeting of the Devonport board of guardians, held on Feb. 5th, the clerk, who was instructed at the last meeting to write to the magistrates' clerk, complaining of Mr. G. A. Rae's charge of two guineas for certifying in the case of a lunatic, read the following reply: "In the case to which you refer there were two separate examinations at different times. Under such circumstances it has been customary to pay two fees of £1 1*s.* each, although the justices may have called in the same doctor on each occasion. This being so we cannot well ask Mr. Rae to reduce his charge." Although several members of the board characterised the charge as "outrageous" the clerk explained that there was no alternative except to pay the fee of two guineas. It seems a pity that the Devonport guardians should complain about being charged the ordinary fees for the examination of lunatics, but it is only another instance showing how many people are always only too ready to reduce medical fees.

A Useful Appointment at Cardiff.

At the meeting of the Cardiff health committee, held on Feb. 1st, Dr. Walford, the medical officer of health, pointed out how important it was for the public health that animals, after being slaughtered, should be subjected to inspection by a person fully qualified to detect any disease, and he suggested that a qualified veterinary surgeon should be appointed for the purpose. After considerable discussion it was decided to carry out the medical officer of health's suggestion. The salary of the new official was fixed at £200 per annum, and he will be required to devote the whole of his time to the purpose of inspecting slaughtered cattle and also the cows in the sheds from which milk is supplied.

The Bath Sanitary Committee and their Medical Officer of Health.

At the last meeting of the Bath sanitary committee the committee agreed, on the recommendation of the sub-committee, to defer giving a trial to bacteriological tests in cases of suspected diphtheria, as recommended by Dr. Symons, medical officer of health. A report was also considered from a special committee with reference to Dr. Symons' proposals for a new system of disinfection, this including the provision of a steam disinfector. The special committee stated that they could not recommend the outlay proposed, and considered that the matter should remain in abeyance. One member thought that certain of the medical officer of health's recommendations might with advantage be adopted and a long and somewhat heated discussion ensued on the subject. The adoption of the report was moved, but an amendment was proposed that a copy of Dr. Symons' report on the subject be sent to each

Hosted by Google

member of the committee. Six members voted for the amendment and six against. The chairman gave his casting vote against it, and the report was consequently adopted. It certainly seems strange that the wise recommendations of their medical officer of health were not adopted by the sanitary committee.

Lunacy in West Wales.

The thirty-second annual report of the medical superintendent of the Carmarthen Asylum, which serves the three counties of Carmarthen, Cardigan, and Pembroke, was issued last week. Dr. Goodall, who again publishes his report in Welsh, states that on Jan. 1st, 1896, there were 559 patients (276 males and 283 females). There were admitted during the year 137 patients (80 males and 57 females). The number admitted was in excess of the average. The average age on admission was thirty-nine for males and forty-one for females. Forty patients were discharged: 29 of these were cured, 6 relieved, 3 unimproved, and 2 were transferred to other asylums. Two female patients were discharged as not insane. There were 50 deaths (25 males and 25 females). On Dec. 31st, 1896, there remained 606 patients (315 males and 291 females). The proportion per cent. of recoveries to admission was 28·15 (20·85 for males and 34·54 for females). The average age at death was for males fifty-two and females forty-eight. During the year additional accommodation for 50 patients was prepared by the completion of the wards.

The Bath Eye Infirmary.

The annual meeting of the Bath Eye Infirmary was held on Feb. 1st, Mr. H. D. Skrine presiding. The report showed that during the past year the work performed had been very satisfactory and beneficent. The honorary treasurer stated that while the year started with £6 due to the treasurer it finished with a favourable balance. It was unanimously decided to present Mr. W. Mardon Beaumont, M.R.C.S. Eng., the honorary surgeon, with an honorarium of fifty guineas for the valuable services rendered by him during 1896.

Visit of Dr. Nansen to Bristol.

Dr. Fridtjof Nansen will give a popular account of his recent expedition, entitled, "Across the Polar Region," at the Victoria Rooms, Clifton, on March 1st. The chair will be taken by Professor Lloyd Morgan, F.R.G.S., Principal of University College, Bristol.

Feb. 9th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Rebuilding of the Royal Infirmary, Newcastle-upon-Tyne.

THE annual court of governors was held in the library of the Royal Infirmary, Newcastle-upon-Tyne, under the presidency of the Right Worshipful the Mayor, last week. The adoption of the annual report was moved by the Mayor, seconded by the Right Honourable the Earl of Ravensworth, and carried unanimously by the large number of governors present. The report showed a large increase in the amount of work and a small decrease in the income of the institution. The expenditure exceeded the income by upwards of £3000. It was stated in the report that the house committee had asked the eminent architect, Mr. Waterhouse, to express an opinion as to the eligibility of the present site for a hospital of 400 beds and as to whether a new hospital could be erected upon the present site and the work of the institution be carried on at the same time. Upon both these points Mr. Waterhouse expressed himself favourably, pointing out the advantages of the present site. Mr. Riley Lord, the ex-Mayor, then moved: "That the House Committee be instructed to prepare and submit to the Queen's Commemoration New Infirmary Fund Committee a scheme for the erection of the new infirmary on the present site." This was carried unanimously, so that the question of site may now be considered to be practically settled. Mr. Riley Lord, to whom is due the credit of raising in a few months £80,000 of the £100,000 required, hopes that it may be possible to lay the foundation-stone of the new building in June of this year, but few people believe this sanguine hope can be realised. Mr. Riley Lord has, however, already accomplished so much more than was considered possible that he may see his wish accomplished.

The Children's Hospital, Newcastle-upon-Tyne.

The annual meeting of this charity has just been held. It shows an increasing amount of work, a decreased income and debt, and, speaking generally, this may be looked upon as the condition of the medical charities in the neighbourhood. The general practitioners complain that the medical charities are abused, and Dr. Jeaffreson in a pamphlet recently issued has voiced this view. There must be some explanation for the position the profession is being driven to occupy, not only here, but in the other large towns of the country. There are men who send round canvassers asking the families of the working classes to allow them to attend them for a few pence a week, and when remonstrated with they reply they are compelled to do this to compete with the medical charities, where advice and costly drugs can be obtained gratis. This, they say, together with unchecked practice by unqualified men, is depriving them of the opportunity of earning a living by legitimate means. Since the working classes commenced to contribute largely to the medical charities and to take a very active part in their administration it is said by the general practitioners there is less reluctance on the part of those who formerly paid for their medical attendance to apply to the charities—institutions which the workpeople are beginning to look upon more and more as medical clubs, maintained by them for their own advantage rather than for that of the class for whom they were originally intended.

Newcastle-upon-Tyne, Feb. 8th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow Medico-Chirurgical Society.

THE usual monthly meeting of this society was held on Feb. 5th, the President (Dr. W. L. Reid) being in the chair.—Dr. Ernest Thomson showed a woman suffering from Ectropion affecting both eyelids on the right side and the lower eyelid on the left. The case was of many years' duration, and one of its most interesting features was the behaviour of the corneal epithelium over the right eye. This had been accustomed to regularly proliferate and dry into a horny scale, which after a time was shed, the patient thus regaining a fair degree of sight after a period of blindness. — Dr. Middleton showed a boy, the subject of a large Fæcal Tumour. The tumour occupied the greater part of the lower abdomen. Below it was very hard and appeared as if moulded to the upper aspect of the pelvic basin, but the upper part could be distinctly "indented" by pressure with the fingers. There was no history of peritonitis and the boy's general health appeared to be quite undisturbed.—Dr. Hinshelwood showed a woman who had recovered from Albuminuric Retinitis. The patient at the end of 1893 had an attack of nephritis with general dropsy and uræmic phenomena. Early in 1894 her vision failed, and this was so marked that when brought to the infirmary she had to be led by a friend. At this time there was double optic neuritis and the characteristic brilliant white spots in the region of the macula. In the course of three months vision had so much improved that the patient could read the smallest test types. The ophthalmoscopic changes very gradually lessened, the neuritis subsided, and the white spots slowly faded away, so that at the end of twelve months nothing remained except a somewhat "filled-up" appearance of the disc, some stippling of the macular region, and the remains of former hæmorrhages in the periphery of the fundus. The albuminuria also had gradually disappeared. Dr. Hinshelwood pointed out the importance of the case as bearing on the general doctrine that the prognosis in renal disease was, when albuminuric retinitis appeared, extremely bad. Whilst this was undoubtedly true, when the disease was interstitial nephritis, the present and other instances showed that a more favourable view was possible when the renal changes were mainly parenchymatous in character. — Dr. Ernest Thomson read notes of a case of Sensory Aphasia with Homonymous Sector-shaped Defect in the Visual Fields. The case was discussed mainly with a view to determine the anatomical diagnosis, and a number of diagrams illustrating the course of the optic pathways in the brain were used to elucidate the argument.

Glasgow University.

A free public lecture was delivered in the Pathological

Hosted by Google

Institute on the 8th inst. by Professor Joseph Coats. The subject of the lecture was Inflammation. This was dealt with in a highly interesting and lucid fashion and was illustrated by numerous microscopic slides and lantern views. There was a large audience. The annual medical ball took place on the 4th inst. Its increasing popularity was manifested by the large attendance of practitioners and students, the ball-room in St. Andrews Hall being, if anything, rather too small for those wishing to dance. The tickets for the dance were all disposed of some weeks before the event. At the February meeting of the Queen Margaret College Medical Club on the 8th inst. a paper was read by Dr. Marion Gilchrist on Milk as a Cause of Disease.

Medical Appointments.

Mr. Thomas Kay, M.B., C.M. Glasg., has been appointed one of the surgeons to the Glasgow Central Dispensary. The position of pathologist to the Glasgow Samaritan Hospital is advertised as vacant.

Poor-law Medical Officers' Association.

The officers of this Association are determined to utilise every opportunity to secure redress of the grievances of which medical officers appointed under the Poor-law complain. The election contest at present proceeding in the Bridgeton division of Glasgow has been regarded as such an opportunity and a deputation from the Association has waited on the two candidates for the purpose. of explaining the views of the medical officers and pressing these views upon the candidates. In reply, Sir Charles Cameron said he was entirely in favour of granting to medical officers dismissed by parish councils a right of appeal to the Local Government Board. In the smaller parishes more especially, personal, political, and religious considerations were apt to influence the relationships of the councils to their medical officers. Protection from such influences was due to the medical men, who had public duties to perform. Mr. Scott Dickson, the unionist candidate, also received the deputation, and promised to use all his influence to secure the satisfaction of their wishes.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Isolation Hospital for Dublin.

THE Dublin death-rate continues very high, scarlet fever and measles being widely prevalent, while the difficulty which was recently experienced in isolating an important case of small-pox has opened people's eyes to the danger of another epidemic of that disease. It will be remembered that no hospital accommodation could be found for that patient, who was, therefore, left in the house in which he was attacked, two officers from the Public Health Department of the corporation being appointed to guard the house and secure its isolation. It has been said that nothing short of a contagious disease seizing a member of the Public Health Committtte would rouse them into making proper isolation arrangements. Something very like that has now occurred, for one of the sub-sanitary officers to whom the isolation duty was entrusted has just died from a virulent form of small-pox. It is stated that he was so rash as to enter the room in which the patient was convalescing and that he then acquired the disease. Every effort was made to secure his isolation and to save his life: a disused house belonging to the corporation was at once supplied with the necessary furniture, bedding, &c., two qualified nurses were placed in charge, but nothing availed to save the poor man, who died on the 4th inst.

Unqualified Assistants.

At the last meeting of the Council of the Royal College of Surgeons in Ireland the following resolution was passed:—"That in the opinion of this Council the employment of unqualified assistants by qualified medical men is most injurious to the interests of the public and the profession, and should be prohibited by the General Medical Council."

Mr. Stoker of the Bengal Civil Service.

Mr. Stoker, who has just been appointed to the important position of Famine Secretary to the Government of the North-west Provinces in India, is a graduate of Dublin University, where he chanced to be on leave when the telegram conveying his appointment reached him. He is now on his way to the worst portion of the famine district.

Belfast Maternity Hospital.

At the last annual meeting held on Feb. 3rd it was reported that during the previous year there had been 270 cases in the house and 170 in the extern nursing department, and there had been no deaths in the house during the year. At the dispensary there were 707 patients. There is a deficit of £60 upon the year's work. The Lady Mayoress, who presided, said as soon as the Queen Victoria Hospital was an accomplished fact she would be glad to lend her assistance to the erection of another maternity hospital in Belfast.

Ulster Medical Society.

At the meeting on Tuesday Dr. M'Donnell read a paper on Birth Palsy; Dr. Lindsay read a short paper on Helps to Diagnosis in Obscure Cases of Scarlet Fever; and Dr. Mitchell read notes of a case of Immediate Enterectomy by Murphy's Button for Gangrenous Inguinal Hernia, and showed the specimens.

Belfast Asylum.

At a meeting of the governors, held on Feb. 8th, an extract from a report made by Dr. Orr, medical officer of health for the Purdysburn district, was read, in which he said that "the sewage works are situated about half a mile up the stream from Milltown, the inhabitants of which complain of water-pollution, and in my opinion the natural purifying influences brought to bear on the water on that course are not sufficient to render it fit for domestic use at Milltown, especially at times of excessive sewage flood." Milltown is a village situated below the Purdysburn Asylum, and the river spoken of flows from the one place to the other. The plan originally adopted was to have the sewage deodorised and afterwards spread over the ground, but instead of that the sewage was run down a trench in the direction of the river, and it was just allowed to find its own way. A number of little trenches were then cut out of the ground, which, however, were found not fit to admit the sewage. The ground was then made as porous as possible, and it was stated by a member of the Board that at the present time this was acting perfectly. It was agreed to refer the matter to a committee with power to engage professional assistance. The chairman of the Public Health Committee of Belfast (Alderman Graham, M.D. R.U.I.) spoke strongly against the adoption of artificial means for dealing with the sewage, and stated that wherever chemicals had been tried they had proved a failure and had to be removed. Alderman Graham's name was added to the Special Committee.

Forster-green Hospital for Consumption and Chest Diseases.

On Feb. 8th a largely-attended adjourned extraordinary general meeting of the subscribers to this hospital was held to confirm the special resolution passed at a general meeting held on the 15th ult., altering the articles of association and raising the status whereby life governors must be donors of £1000 instead of £300 as formerly. This change has been brought about by the fact that the income from £300 would be insufficient to meet the expense of an in-patient. Under the new rules which were passed donors of £300, instead of being life governors, have only certain privileges for a limited number of years.

Election of Dispensary Medical Officer for the Whitechurch District, Cork.

A meeting of the Whitechurch Dispensary Committee was held last Friday for the purpose of electing a medical officer. There were two candidates—Mr. Donovan and Mr. Lynch. The former was elected by a majority of one, but as objections have been lodged with regard to the qualifications of some members of the committee the final decision of the Local Government Board is looked forward to with some interest.

An Octogenarian Athlete.

Athletic sports were held at Freemount, County Cork, last week, and a man named James Loder, aged eighty-two years, covered 33 ft. in three standing jumps. Several young men failed to come within 3 ft. of the veteran athlete's distance. Old Loder weighs only 8 st. and is remarkably vigorous. It is asserted his father lived to the remarkable age of 110 years.

Precautions against the Plague.

THE question of taking measures against the invasion of the plague has entered the domain of practical politics. A.

Hosted by Google

decree published on Sunday, the 7th inst., absolutely prohibits the landing in any French ports of merchandise shipped from infected Indian localities. Under an Act brought in by M. Barthou false declarations can be punished by imprisonment, the term varying from one to five years, and by a penalty of from 1000 fr. to 3000 fr. It is interesting to recall that the old law punished such false declarations with death. The new law recognises the possibility of extenuating circumstances and allows the jury only to condemn the accused to hard labour. The Chamber has voted a sum of 40,000 fr. for expenses of the delegates to the Venice Conference and for the exceptional expenditure which the prescribed measures will bring about in the various ports. The Sanitary Council has been specially called together to lay down regulations for passengers and to determine the conditions under which quarantine should be imposed. Landing is prohibited in all the French ports in the Mediterranean. Quarantine is to last eight days for passengers disembarking at any ocean port and four days for those arriving at channel ports. Three vessels from India have already been precluded from disembarking their passengers at Marseilles on account of the hostility of the inhabitants, who threaten to break into riot. An English ship entering Havre has not been able to land her cargo, and even the mail coming by the *Yarrow* has not been able to unload. Letters have only been received after having been disinfected in a stove.

The Serum Diagnosis of Typhoid Fever.

At a meeting of the Society of Biology MM. Widal and Sigard communicated an improvement in their method of diagnosis. Till now the reaction by agglutination has been obtained by mixing fresh cultures of the typhoid bacillus with the serum of the patient under investigation. These bacilli when killed by heat lose their agglutinating power, and investigators have remarked that when the bacilli are destroyed with due care, whether by a temperature of between 57° and 60° C., or preferably by adding a drop of formal to the culture, they preserve, even though dead, their property of agglutinating the serum of typhoid fever patients for as long as three months. Tubes can, therefore, be prepared with formol and preserved in the laboratories of hospitals, preventing the necessity of using fresh and virulent cultures—an innovation of considerable importance to general practitioners.

Le Service Médical de Nuit.

A new decision has been taken by the Municipal Council more favourable to the medical man. The sum of 29,000 fr. has been added to the original grant, and each *quartier* is to receive a certain sum calculated upon the mean annual number of night visits made during the last two years. The fee for these visits, which was originally proposed—i.e., 8 fr.—has finally been set down at 10 fr., and to all intents the old organisation has been re-established. The present service is indeed more effective. In certain districts the population has recently increased and the number of visits paid has also increased in proportion. Under the old *régime* if an epidemic had broken out, despite the increased number and seriousness of the cases, the annual sum received would have remained the same. Now the remuneration of the medical officers will be proportionate to their work, and the fees will be recovered from the patients by the inspector of taxes for the district. The officers of the service must have French qualifications.

Dissatisfaction in the French Army Medical Service.

Resignations have become more and more numerous in the Service. Half the medical officers leave the army as soon as they have completed thirty years' service—that is to say, when they have just established a right to a retiring pension. The general complaint is that promotion is unjustly managed. Formerly promotion went by seniority, now it is dictated by merit. As a consequence, it is said that some arrive at the highest places at an age too young to do their work properly, the complaint being made that favour plays a great part in the selections for promotion. The Government is beginning to fear that the Service will be short-handed.

A Supporter of Quackery.

Dr. Guermonprez, surgeon to the hospital at Lille and Professor at the Catholic University at that town and a well-known gynæcologist, has been boycotted by the profession for having accepted the medical certificates of a priest who practises medicine illegally at Sens and who has been many times convicted for his misdemeanour. Dr. Guermonprez, whose religious convictions are responsible for his attitude, attempted to lighten the rigors of the law for the priest, and the Society of Surgery, of which he was a member, has decreed that he was to blame and has removed him from its roll. In addition to the important position I have mentioned Dr. Guermonprez was medical officer to the Chemin-de-fer du Nord, a very important post, so that we have the position that the chief medical officer of the service, the absolute master over his subordinates, has been publicly reproved by the medical profession unanimously. The case illustrates the absolute necessity for a tribunal of professional honour in France.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Professor Koch's Work in South Africa.

PROFESSOR KOCH'S investigation of the cattle plague in South Africa forms the subject of a recent article in the *Norddeutsche Allgemeine Zeitung*. One of the first places which he visited after arriving in the colony was the leper asylum on Robben Island in Table Bay, and he is said to have expressed his satisfaction with the general arrangements of the establishment as well as with the bacteriological work accomplished in the laboratory. The party included representatives of the Colonial Government, the German Consul-General, and several medical men. On Dec. 3rd he left for Kimberley, where the principal part of the work of investigating the cattle plague will be undertaken. He was accompanied by his assistant, Dr. Kohlstock, and also by Dr. Turner, a medical officer of the Colonial Government. It was arranged that a laboratory should be fitted up at a farmhouse about two miles from the town, and whilst the requisite alterations were being made Professor Koch went to Taungs, a town in the Kaffir country about 200 miles from Kimberley, where more than 20,000 head of cattle have died from the epidemic, so that there was abundant opportunity of observing the disease, of performing necropsies, and of collecting morbid specimens. On Dec. 8th the party returned to Kimberley, where the laboratory was then in working order, and eight animals were inoculated with infective material brought from Taungs. The inoculations were made in the mouth and nose, every precaution being taken to ensure isolation and to guard against any accidental extension of the disease in the Kimberley district. One of the inoculated animals very soon died with symptoms of cattle plague, and the pathogenic material obtained from it was used for the inoculation of a fresh series. Professor Koch is very pleased with the arrangements which have been made by the colonial authorities for facilitating his researches, and finds that everything has been done to render his visit agreeable. The foregoing particulars have only appeared in an ordinary newspaper; a far more detailed and satisfactory account of the cattle plague inquiry will no doubt be communicated to the medical press on the return of Professor Koch and his assistants. The German Government is said to have requested him to visit Bombay for the purpose of investigating the bubonic plague.

The Prescribing and Dispensing of Medicines.

In the year 1725 a law was passed forbidding medical men to direct their patients to have their prescriptions dispensed by specified pharmaceutical chemists, an exception being made only in the case of some special medicines which are not contained in the German Pharmacopœia, and therefore require a previous agreement between the prescriber and the dispenser. Patients are entitled to have medicines made up at any pharmaceutical establishment entirely at their own discretion, and a case under the old statute has just been brought before the law-courts. A medical man in Berlin, whose professional standing was not very high, had displayed in his waiting-room a request that his patients would have their prescriptions dispensed at a pharmacy in the neighbourhood, and he also announced that a so-called "unguentum antiluposum," by means of which he pretended that lupus could be cured, was only to be obtained there. Legal proceedings were thereupon taken, and in the course of the trial the defendant's counsel argued that the statute which was said to be infringed had been abrogated or rendered obsolete by recent legislation. Much amusement was caused by the reading of a paragraph from the law prohibiting chemists from giving Christmas presents to medical

Hosted by Google

men. The defendant was convicted and fined 300 marks (£15), but has appealed against the decision.

The late Sir Thomas Spencer Wells.

The announcement of the death of Sir Spencer Wells was received in Berlin with feelings of sympathy and regret. The current numbers of our leading medical journals, the *Deutsche Medicinische Woohenschrift* and the *Berliner Klinische Wochenschrift*, appeared before the news arrived, but the principal newspapers publish detailed obituary notices eulogistic of the deceased, pointing out that German surgery owes much to his example, as was fully recognised by competent representatives of this branch of medical science on the occasion when his portrait was placed in the collection of portraits of eminent surgeons preserved in Langenbeck House. Sir Spencer Wells was one of the few honorary members of the German Surgical Association; he was present at the celebration of its twenty-fifth anniversary in 1896 and was very cordially received.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The University Riots.

FROM Turin to Palermo the whole academic world has for the past week been in a ferment. At some universities the undergraduate "demonstranto" have been so violent as to necessitate military intervention; in others the session has had to be suspended with half at least of the "annus academicus" sacrificed for professors and students equally. As I write, even the secondary schools have caught the revolutionary contagion and are joining in the demonstrations against the Minister of Public Instruction (Signor Gianturco). Meanwhile that able and efficient functionary has the sympathy of all the judicious and right-feeling part of the community—sympathy which will sustain him in asserting the authority of Government and in strengthening the hands of the professoriate. The *Opinione* (the Prime Minister's organ) concludes a grave and trenchant article on the situation by deploring the premature spirit of party which prevails in the Italian seats of learning and denounces those journals which, for political purposes, encourage that spirit and foster a state of things which must be disastrous to the next generation while well-nigh paralysing the present. "From every side," it says, "there is an appeal to energy, to firmness in the interests of the students themselves, for the decorum of the universities, and for the dignity of science. The severer and the more effective the rigour the more grateful will be the families whose sons are compromised; the more true liberty is respected the more thankful will be the youths when, the momentary excitement having died down, they realise the deplorable results of rebellion and the evil inspiration of its promoters." Italy has much leeway to make up in education, particularly on its professional side. It will be long, indeed, before she resumes the place she has ceased to hold in the scientific arena. The more promptly and peremptorily, therefore, she "puts down her foot" and restores discipline in her academic halls the better will she consult her own interests at home and strengthen her reputation abroad.

Professor Bizzozero on Small-pox.

Small-pox, like the poor, "is always with us"—a condition of things the less likely to cease now that the anti-vaccinationist is letting his voice be heard. To this type of agitator an opportune answer, which is also a grave rebuke, has just been given by the Professor of General Pathology in the Subalpine School, Dr. Bizzozero, whose zeal and skill in the domain of public health is only second to the laboratory work which has made him renowned. "Italy," say the agitators in question, "is a well-vaccinated country, and yet she is perennially scourged with small-pox." Now of these two affirmations, rejoins Professor Bizzozero, the second is true, because the first is not. Small-pox reaps, he says, a yearly harvest of victims; from 1887 to 1889 it cost the country well-nigh 48,000 lives. But just before that epidemic there was no law making vaccination compulsory. The only statutory precaution in force was one, indirect in its incidence, requiring an inoculation certificate for admission to schools. Statistics for 1885–86 show that for every thousand births there was an average of 757 vaccinations, comprising all the "inoculations" practised at all ages. For every 1000, therefore, there were 243 persons not vaccinated. The contingent of those remaining unvaccinated throughout life cannot be determined with accuracy. The nearest approximate estimate, says Professor Bizzozero, is drawn from army medical statistics. In the quinqennium 1884–88 which preceded the epidemic, out of 683,836 soldiers 12,165 had not been vaccinated—that is, 1·77 per cent. of non-vaccinated, or, transferring the calculation to the 30,000,000 Italians, there were 527,000 persons absolutely defenceless against the malady. So much, continues Professor Bizzozero, for the non-vaccinated. As for the vaccinated, nearly all of them had had but one "inoculation," and that in infancy. This is deduced from the fact that in the two years above mentioned the re-vaccinated numbered as few as 6·5 per 1000, so that to the non-vaccinated group we must add another much larger group—that of those in whom by the remote date of the "inoculation," the immunity was imperfect, if not entirely extinct. What wonder, then, asks Professor Bizzozero, if small pox finds in Italy so favourable a nidus for its spread? But are we to infer, he continues, that vaccination is useless? No. The one possible inference is this—against small-pox a single vaccination is not enough. Nor does greater value attach to the objection that vaccination is useless because small-pox attacks particularly children under five years of age, when the immunity it is supposed to confer should be at its maximum. Let us see, says Professor Bizzozero, what, according to age, has been the mortality from small-pox in the two years when the epidemic was at its height:—

DEATHS FROM SMALL POX IN EVERY 10,000 INHABITANTS.

	1887.	1888.
Up to 1 year of age	59·5	67 5
From 1 year to 5	18 4	25 2
From 5 years to 10	4 2	5 1
,, 10 ,, 15	1 9	2 0
,, 15 ,, 20	2·4	2 2
,, 20 ,, 40	2 9	2·3
,, 40 ,, 60	2 5	1·9
,, 60 ,, 80	1 6	1·3
,, 80 ,, upwards	0·9	0·8

These statistics prove that the infantile mortality is enormous, but it proves nothing against vaccination. In fact, it demonstrates that less than a third of those born are vaccinated within the year of birth; of the other two-thirds, some are vaccinated sometimes in the third or fourth year from birth, some are not vaccinated at all. Proceeding to examine the figures of those years which prepared the soil for the epidemic, Professor Bizzozero finds that of 1000 children below one year there were 685 unvaccinated, and as the births in that period averaged in one year 1,135,000, so every year there were about 777,000 children unvaccinated among whom small-pox could make free havoc. In the years of life immediately following on the first the number of the vaccinated augments and the mortality sinks to a small figure. "It is not true, therefore," concludes Professor Bizzozero, "that small-pox reaps more victims among children *in spite of* the fact that the immunity ought to be stronger in them. It reaps more victims *because of* the immunity conferred by vaccination being neglected in the greater part of them."

Feb. 8th.

NEW ZEALAND.

(FROM OUR OWN CORRESPONDENT.)

Faith-healing in the Colonies.

NEW ZEALAND seems to be a happy home for every kind of unfeathered quack, the Dierks case, referred to later, being an excellent example. There must be something in the climate which is especially favourable to cranks and impostors of all kinds. It seems quite clear that whenever such a one makes his appearance among us, whether he is a "boomer" of a patent medicine for resuscitating men's bodies or of a new patent creed under the heading of a Christian scientist or humbug of whatever kind, he is not only certain of a patient hearing, but of a more or less enthusiastic support. New Zealand is constantly overrun with quacks of various descriptions, almost all of whom reap a rich harvest from the credulity and infirmities of the colonial people. A man

Hosted by Google

calls himself a "Professor" (of this, that, or the other art), and if he be only impudent enough in his assertion and advertises enough people rush to him with fees as eagerly as the Children of Israel in the wilderness flocked to the feet of the prophet who held aloft the life-saving image of the brazen serpent. There is no doubt that faith-healing in one form or another has been practised ever since man made his appearance upon earth—i.e., the curing of diseases without medical or hygienic treatment—by simply inducing a healthy interaction between body and mind. For instance, Charles II. is said to have cured a number of cases of scrofula by a touch of his hand; and it is well known that the medicine man of the Maori or the ordinary negro tribes is a faith-healer. On the same principle did Prince Hohenlohe, Father Gassner, and countless others cure by faith. The doctors of the Salpêtrière in Paris work—so they say—miracles quite as unique as any on record by faith plus hypnotism. This is all true up to a certain point; but the patients, when the excitement is over, usually find themselves not only poorer in pocket, but worse in health for their experience. In this colony (as elsewhere) it is certain that the "workers of cures" rarely remain long enough in one place to await the results of their treatment. In this policy they show their wisdom. Thousands of pounds must certainly go into the pockets of globe-trotting quacks out of New Zealand dupes every year; worse than this, unskilful treatment as a rule intensifies the ailment it professes to cure; but occasionally a "miracle is effected"—apparently attributable to the means used—and then numbers are deluded by the testimony given by the patient, who is, as a rule, sincere in his desire to assist humanity! New Zealand imports about £40,000 worth of patent medicines annually. The Custom duties on this amount to 35 per cent. Trade profits have now to be added before the patent or proprietory medicine can be obtained by the public, so that the public expenditure on this luxury can be easily calculated. When one considers that the basis of most of these patent medicines is a remarkably effective but cheap drug (aloes), and that a little soap—being largely used in pill-making—and a bit of ginger are added to warm the compound up, it is by no means difficult to comprehend how fortunes are made by the original vendors. The salves and ointments are compounded of materials of a most homely and inexpensive character. The attractive appearance of the package or the euphonious name is probably as responsible for the favour in which they are held as any real good which can be derived from the consumption or use of the medicine itself. There is, I should imagine, no community under the sun which, in proportion to its numbers, consumes annually more patent medicines from all quarters of the globe than do the residents of the Australian colonies.

New Zealana Medical Defence Union.

Dr. Irving of Christchurch and his colleagues are to be congratulated on having at last found themselves in a position to register the above company. Legal difficulties prevented the scheme being carried through last year at the meeting of the association held at Christchurch; but since that time it has been ascertained how the home societies met those obstacles and the difficulties have been surmounted. Briefly put, the above union is a limited liability company in £1 shares, which form the capital, and this will not be called upon except to meet such heavy expenses as cannot be met out of the annual subscriptions, which amount to only 5*s.* per member. Calls up to the full amount of the guarantee may at any time be requested if such are required for urgent and special objects. Provisions are also made whereby the annual subscription can be increased; this is for the object of preventing calls on the capital of the company for the expenses incurred in the ordinary carrying on of its functions. That the union will have a long career of usefulness to the profession seems certain, and Dr. Irving is to be commended for his perseverance in carrying out the details.

The "New Zealand Medical Journal" Amalgamates with the "Australasian Medical Gazette."

It appears from the last two annual general meetings of the New Zealand Medical Association that the members have been anxious to bring about the above negotiation. The New South Wales Branch of the British Medical Association, who are the proprietors of the *Australasian Medical Gazette*, have arranged that eight pages of their monthly journal shall be devoted entirely to New Zealand matter. They also undertake to supply the magazine to all our members, post paid, for the charge of fifteen shillings per annum, the payment to be made through the New Zealand branch. The issue of Oct. 1st, 1896, then of the *New Zealand Medical Journal*, was its last production under the old conditions. The little journal has been very ably edited formerly by Dr. Colquhoun and latterly by Dr. Barnett (both gentlemen hailing from Dunedin, where the journal was published quarterly). That the *New Zealand Medical Journal* did not die a natural death from pecuniary embarrassment is made clear by the balance-sheet which the present management have published in its last isssue, for it shows a cash balance of £10 16*s.* 8*d.*, in addition to sound assets which are estimated to be worth £80 at least. The late journal has played its part well, for it has been the means of doing more than interchanging ideas among the busy general practitioners scattered about the colony and who are oftentimes quite unable to attend even the meetings of their own special branch, much less the annual general meetings of New Zealand medicos. Many very valuable papers have from time to time appeared in its pages, most of which, stamped with originality and dealing with general practice in the colony, are well worth preserving for reference. It will be seen by-and-by how the new arrangement works, but I should not be surprised to discover that before many years are over our heads New Zealand will find it imperative to have a medical journal of its very own.

Interesting Case of an Action for Malpractice: Damages for Plaintiff £50 and Costs.

The case of Tuku Wunu, an infant, suing by his next friend Wiu Hamiona, his father, *v.* Dierks has recently been tried before his Honour Judge Kettle, and has excited great interest. It is as a general rule very difficult to run quacks to earth, but when they practise under the cloak of religion the task becomes doubly difficult. This person Dierks is a Lutheran missionary, who for years past has treated patients and received payment for rendering medical services, not only to the Maoris, but also to the settlers along the west coast of the north island. He undertakes the cure of cancer by pricking over the area of the tumour with various kinds of needles, followed up with friction of the general surface, and has caused in numerous instances, as it is needless to say, intense suffering as a result of his method of treatment. Judge Kettle's judgment covers all the ground, and is well worth recording. As an instance of the amount of "confidence" some of the settlers of Maxwelltown have in the ability of this charlatan they met together and subscribed the full amount of the damages and costs in which Dierks had been mulcted. It is a matter of satisfaction, however, to note that most of the enlightened members of the community declined to show any substantial sympathy with such a clerical humbug. The judgment is in substance as follows: "The plaintiff, a native lad about fourteen years of age, states that an injury to his leg was unskilfully treated by the defendant, and he claims £500 as damages. On March 9th he was struck on the shin with a board and on March 13th or 14th he took to his bed. On March 15th the defendant visited him, professed himself competent to treat the injury, prescribed, and continued in attendance till Dr. Saunders, who arrived on March 18th, pronounced the case to be acute periostitis and necrosis. All the medical experts who gave evidence and the medical authorities to whom I was referred agree that early and energetic treatment is of the greatest importance in such a case. There can, I think, be no doubt that the defendant's treatment was improper and unskilful, and he is, under the circumstances of the present case, liable to the plaintiff. [Bevan on Negligence, second edition, 1895, pp. 1397,1399 and 1400, and other authorities were here quoted.] If a person not professing to have any special skill undertakes on an emergency and gratuitously to set a broken arm or leg he would only be liable, if at all, in the event of gross negligence; but in the present case the defendant professed to be competent and received money for his services. In all probability necrosis had set in before the defendant took the case in hand, but I think he is liable for the increased injury to the plaintiff owing to his improper and unskilful treatment from March 15th to March 18th, and I assess the damages at £50, for which judgment will be entered with costs, court fees, counsels' fee, and witnesses' expenses."

Dec. 24th, 1896.

Obituary.

JAMES ELLISON, M.D. LOND., M.R.C.S. ENG., L.S.A.,

SURGEON TO HER MAJESTY'S HOUSEHOLD, WINDSOR.

DR. ELLISON, of Windsor, whose death, at the age of seventy-nine years, took place on the 31st ult., was born in India, his father being in the service of the East India Company. He was sent to England for his education and in 1834 was articled to Dr. Thomas Walker of Peterborough, with whom he remained as pupil until 1839, when he became a student at St. Bartholomew's Hospital. Having qualified, he returned to Peterborough, where he had obtained the appointment of house surgeon to the dispensary and infirmary; this post he relinquished that he might pursue his studies at the University of Heidelberg, and finally, in 1846, having graduated in the University of London, Dr. Ellison settled in London at the corner of Wimpole-street and Great Marylebone-street. After practising there successfully for six years he entered into partnership with the late Mr. Henry Brown, who held the post of surgeon apothecary to the Queen's Household, and in 1851 Dr. Ellison settled in Windsor. He was soon after appointed surgeon to the Windsor Royal Infirmary (an office which he resigned some years since) and subsequently he was appointed surgeon apothecary to Her Majesty's Household. This post he held to the day of his death, being associated in the appointment with his partners, Dr. W. Fairbank, and his son, Dr. W. A. Ellison. In 1847 Dr. Ellison married the daughter of his first professional teacher, Dr. Walker. This brief enumeration of the steps in Dr. Ellison's professional life gives no insight into the man. Naturally endowed with high ability, earnest and painstaking in all he did, Dr. Ellison left school an unusually well educated lad, and throughout his long life he never ceased to devote the time he could spare from his professional work to the improvement of his mental culture. He was an excellent linguist, and was deeply interested and widely and accurately informed in all branches of natural science. He worked with the telescope and the microscope in an exhaustive manner; he read deeply, his reading covering a wide range of subjects; he was an excellent water-colour artist; and had a thorough knowledge of music. With all this store of knowledge he was absolutely free from ostentation, and those only who knew him intimately were aware of his extensive culture. Thoroughly up in all branches of his profession, possessing tact and judgment, with well-trained senses, he was of necessity a successful practitioner, and his thoughtful face, and grave, forcible manner doubtless contributed to win for him the confidence of his patients, while his kindness, his high standard of honour, his rectitude, and his modesty brought him the affection and respect of his patients, friends, and neighbours. From a letter addressed by Sir James Reid, K.C.B., M.D., to a member of the family we quote the following gratifying and high testimony to his worth: "I received your telegram announcing Dr. Ellison's death, and lost no time in informing the Queen, who commands me to express to yourself and to the other members of the family Her Majesty's sincere regret at the loss of one who has served her so long and so faithfully, and for whom she entertained the greatest regard," the writer of the letter in which this message was conveyed adding, "Dr. Ellison was one of the most unaffected, upright, and honourable men I ever knew, and whose high-mindedness was never more in evidence than during the protracted and distressing illness which he had borne with such exemplary fortitude and patience."

Dr. Ellison was no less active in body than in mind and in early life was proficient in the various athletic pastimes of the period. He joined the volunteers at the commencement of the movement, and notwithstanding the calls of a very large general practice in Eton, Windsor, and the neighbourhood, with frequent calls for consultation, he served first as captain and subsequently as surgeon to the regiment for a period of twenty-eight years. Dr. Ellison retained his upright figure and quick, active step until the occurrence of his illness in 1895. At that time symptoms of malignant stricture of the œsophagus showed themselves; he had the professional help of Mr. Lennox Browne, Dr. Semon, and Mr. Charters Symonds. The latter surgeon—when, in December, 1895, thirteen months before Dr. Ellison's death, the power of swallowing had gone—succeeded in getting a tube through the stricture, by which tube food was administered up to Jan. 30th, 1897. The death of Dr. Ellison takes from the ranks of the profession a skilful, accomplished, honourable, and loveable gentleman.

DR. NIKOLAI ZDEKAUER.

THE death occurred on Jan. 15th (27th) of ex-Professor Nikolai Feodorovitch Zdekauer, one of the most distinguished of Russian physicians and sanitarians. The deceased was a Finn by birth; he was born in Sveaborg in 1815, and was therefore in his eighty-second year at the time of his death. He was educated in the St. Petersburg Army Medical Academy, where he obtained the diploma of *lékar* as long ago as 1838. From 1848 to 1863 he filled the chair of Pathological Anatomy in the Academy. He took his M.D. degree in 1842. He was the author of several works on clinical subjects, among which may be mentioned a volume of clinical lectures, works on heart disease, small-pox, influenza, and cholera. But of even greater importance than his clinical labours were his successful endeavours in the fields of hygiene and public health. It was the successive cholera epidemics in the middle decades of the century which first drew the attention of Zdekauer to the importance of these subjects. He was fortunate in gaining the ear of those in power and was able very soon to give practical effect to his teaching. He studied deeply the questions of lighting, heating, ventilation, and drainage, and there were few public buildings in St. Petersburg in which great improvements were not introduced in all these points as the result of his initiative. Among those who actively coöperated with him in these matters was General Todleben, of Crimean fame. As early as 1850 Zdekauer endeavoured to form a society in St. Petersburg on the lines of the Analytical Society of London, which should have as its object the supervision of the food-supplies of the capital. This endeavour was not immediately successful, though it led to the formation in 1852 of the first Russian National Health Society. This society existed only for ten years, but it is said to have done much in that time to improve the sanitary condition of the Russian capital. In 1877 Zdekauer represented Russia at the International Congress of Hygiene at Brussels, and on his return from this he was successful in forming a new society, the present Russian National Health Society. He was elected the first President and remained in this post until within a few years of his death. Dr. Zdekauer was also a member of the Medical Council, of which he was President for five years, from 1884 to 1889. He took an active part in the scientific committee of the Army Medical Department, was a member of the Red Cross Society and of many other Russian and foreign societies, and was President of the Sanitary Commission of the Government of St. Petersburg. In 1860 he was appointed *leib-medik-consultant* to the Imperial family; he was the recipient of many decorations, and when in 1888 he completed his jubilee of public service the late Emperor Alexander III. presented him with a handsome snuff-box, set with diamonds and bearing the Tsar's portrait. The cause of death was heart failure, apparently the result of old age. The funeral took place on Jan. 20th (Feb. 1st.) and was a most imposing ceremony. Among those present were the Grand Dukes Vladimir, Paul and Constantin, representatives of a large number of public institutions, and many leading members of the medical profession and of society.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. C. Corradi, Lecturer on the Ear and Throat in the University of Turin.—Dr. Bates, late Professor of Medicine in the California University, San Francisco.—Dr. Sudakevich, Professor of Pathological Anatomy in the University of Tomsk.—Dr. G. Münch, Professor of Pathological Anatomy in the University of Kieff.

A VACCINATION RECORD.—In the Steyning Union (Sussex) it has been reported that last quarter 1,493 children were born in Hove, of whom only seventeen were unaccounted for. Out of 141 born in the rural district, only the odd one remains to be accounted for.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The Senate have conferred on Dr. Alfredo Antunes Kanthack, F.R.C.S., of St. John's College, the complete degree of Master of Arts *honoris causâ*. Dr. Kanthack's valued services as John Lucas Walker student and as Deputy-Professor of Pathology have thus received a merited recognition by the university. The stipend of £250 a year has been assigned to Dr. Joseph Griffiths, F.R.C.S., for fulfilling the duties of the Professorship of Surgery during the period of suspension.

FOREIGN UNIVERSITY INTELLIGENCE.—*Christiania:* Dr. Blom Leegard has been appointed Professor of Neurology, Dr. C. P. M. Baeck Professor of Dermatology, Dr. H. Ström Professor of Surgery, Dr. Axel Th. Johanessen Professor of Pediatry, and Dr. V. C. Uchermann Professor of Otology with Laryngology.—*Naples:* Dr. Calabrese, Dr. Polignani, Dr. Oro, and Dr. Leocato have qualified as *privat-docenten* of Medical Pathology, Ophthalmology, Dermatology, and Midwifery respectively.—*Prague* (*German University*): Dr. Julius Pohl has been appointed Professor of Pharmacology and Pharmacognosis.—*Strassburg:* Dr. P. Manasse has qualified as *privat-docent* of Otology.—*Turin:* Dr. Martinotti has qualified as *privat-docent* of Psychiatry.—*Vienna:* Dr. Rille and Dr. Spiegler have qualified as *privat-docenten* of Dermatology and Syphilis.—*Zürich:* Dr. Wilhelm Felix has been appointed Extraordinary Professor of Anatomy.

THE proceeds of Mellin's Food Art Competition, amounting to £247 10*s.*, have been distributed amongst the undermentioned hospitals:—Alexandra Hospital for Children with Hip Disease, £22 10*s.*; Belgrave Hospital for Children, £22 10*s.*; Cheyne Hospital for Sick and Incurable Children, £22 10*s.*; East London Hospital for Children and Dispensary for Women, £22 10*s.*; Evelina Hospital for Sick Children, £22 10*s.*; Hospital for Sick Children (Great Ormond-street), £22 10*s.*; North-Eastern Hospital for Children, £22 10*s.*; St. Mary's Day Nursery and Hospital for Sick Children, £22 10*s.*; Victoria Hospital for Sick Children, £22 10*s.*; Edinburgh Royal Hospital for Sick Children, £22 10*s.*; and Brighton Royal Alexandra Hospital for Sick Children, £22 10*s.*

THE MANCHESTER MEDICAL GUILD.—The third annual report of this guild was held in the Victoria Hotel, Manchester, on Jan. 27th, Alderman F. H. Walmsley, J.P., being in the chair. The annual report and statement of accounts were received and adopted. Forty-five new members had joined during the year and two had resigned, leaving the number of members 156. The council had held twenty meetings and dealt with many matters of importance to the local profession, whose interests it had endeavoured to safeguard and maintain. A special inquiry had been made into the subject of "Club and Allied Practices," and an interim report was presented thereon. Medical guilds had been formed at Stockport, Wigan, and other places, showing that the need for local organisation was becoming more and more recognised. The following honorary officers were elected:—President: Mr. F. H. Walmsley, J.P. Vice-Presidents: Mr. Henry Aldred, J.P.; Dr. Henry Ashby; Dr. C. H. Braddon, J.P.; Mr. Samuel Buckley; Mr. William Crosby; Dr. J. Dreschfeld; Dr. A. M. Edge; Dr. C. E. Glascott; Dr. Alfred Godson, J.P.; Mr. James Hardie; Mr. Francis Hepworth, J.P.; Mr. Thomas Jones; Dr. David Little; Dr. T. N. Orchard; Dr. D. Lloyd Roberts, F.R.S. Edin.; Dr. Henry Simpson; Mr. F. A. Southam; Dr. Graham Steele; Mr. G. A. Wright; Mr. Walter Whitehead, F.R.S. Edin.; Dr. Sam Woodcock, J.P.; and Mr. A. H. Young. The officers and council were elected as follows:—Chairman: Dr. J. Dixon Mann. Vice-Chairman: Dr. C. E. Glascott. Treasurer: Dr. Chas. G. L. Skinner. Hon. Secretary: Dr. Alexander Stewart. Council: Mr. S. Bagley; Dr. W. B. Bell; Dr. I. Blore; Mr. W. G. Booth; Dr. W. F. Boycott; Mr. G. H. Broadbent; Dr. E. Vipont Brown; Mr. R. J. Dearden; Dr. R. Forsyth; Mr. C. R. O. Garrard; Dr. J. H. Godson; Mr. W. E. Husband; Mr. E. L. Luckman; Mr. J. A. Palanque; Mr. G. H. Pinder; Mr. J. Ratcliff-Gaylard; Mr. F. Leyland Roe; Dr. A. B. Ritchie; Dr. J. Prince Stallard; and Mr. R. H. Wolstenholme. Auditors: Mr. R. G. Heathcote and Dr. H. Monteagle.

THE MANCHESTER MEDICAL SOCIETY.—A meeting was held on Feb. 3rd, Dr. Graham Steell, President, being in the chair.—The President delivered the annual address before the members of the society, his subject being Heart Disease, a Retrospect of over Five-and-Twenty Years.—Dr. J. E. Platt read a communication upon Some Points in the Diagnosis and Treatment of Fractures of the Lower End of the Humerus. The observations were based upon a series of sixty cases which he had treated at the Manchester Royal Infirmary. The cases included eleven of separated epiphysis, one of partial separation of the epiphysis, seven of transverse fracture at or near the condyles, three T-shaped fractures, twenty fractures of the external condyle, eleven of the internal condyle, and seven of the internal epicondyle. The manner of growth of the lower epiphysis of the humerus and the fact that separation of this epiphysis as a whole probably never occurs after the age of thirteen years were referred to. The occurrence of cubitus valgus and varus after oblique fractures of the condyles was mentioned, and a means of preventing these deformities when the fractures are treated with the elbow flexed was described. The importance of immediate reduction of the displacement of the fractured portions of bone was insisted upon. The relative advantages of anterior and internal angular splints in the treatment of these cases were discussed and the former was recommended, since it had been found to keep the fragments in good position much more readily than the latter. For the reduction of the swelling around the elbow-joint a slight amount of pressure with cotton-wool had been found more effective than evaporating lotions. The use of passive movements of the elbow-joint in the treatment of these fractures was condemned. Some of the cases had been treated with passive movements, others without passive movements, and it was pointed out that the latter cases had, on the whole, recovered in a shorter period of time than the former. Seldom had it been found, except in cases where the displacement of the fragments was not properly remedied, that those fractures which were treated without passive movement left any very prolonged stiffness of the elbow-joint.

LITERARY INTELLIGENCE.—We are asked to state that a series of popular text-books on nursing will shortly be issued under the title of the "Burdett Series," by the Scientific Press. The first of the series, which is entitled "Hints on District Nursing," by Miss Amy Hughes, Superintendent of Nurses, Bolton Union Workhouse, will be published immediately. The books, we are informed, will be produced in a handy pocket size, and are exceedingly well written, nicely printed, and bound in cloth. On these points we will advise our readers when we have the volumes before us.—Messrs. J. & A. Churchill will shortly publish "A Short Practice of Midwifery," giving the treatment adopted in the Rotunda Hospital, Dublin, by Henry Jellett, M.D., assistant master. The author states that he has written this little work, first, because he was "requested to do so by several of the students attending the hospital; secondly, because the extremely successful results following the treatment adopted seem to warrant its publication." There is a preface by Dr. Smyly, late master of the hospital, and an appendix containing the statistics of the Rotunda Hospital for the last seven years.

THE ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AT VENTNOR.—The report of the twenty-eighth year of the operations of this well-known hospital for chest diseases was read by the secretary, Mr. Ernest Morgan, and adopted at the annual meeting of governors held on Feb. 11th, at the London offices, 34, Craven-street, Charing-cross. The report showed that the work had gone forward steadily and satisfactorily. The board of management have accommodation for 134 men and women patients in ten blocks of houses situated in the Undercliff of the Isle of Wight, each patient being provided with a separate bedroom facing south and overlooking the sea; and while every bed continues to be occupied, there were at the end of the year 135 approved applicants for whom, unfortunately, there was not room in the hospital. An effort is being made to increase the accommodation by the erection of another block of houses, which it is hoped may be erected, as many of the other houses have been in the past, in memory of a deceased relative or friend, by some wealthy, benevolent donor, the cost being £2000; and H.R.H. Princess Henry of Battenberg has promised to lay the foundation stone of the new block in July next. The

Hosted by Google

total receipts in 1896 amounted to £11,831 (including £2543 from a festival dinner, but nothing whatever from legacies), and the expenditure was £12 031. The number of patients treated was 810, some of whom were resident as long as thirty weeks, though the average stay was eight weeks; 32 died, and 79 per cent. were improved in health by treatment. As the annual subscriptions are only £2394, an effort will be made this year to obtain the necessary funds for maintenance by a special appeal. Mr. P. B. Burgoyne was unanimously elected treasurer of the hospital. The re-election of the retiring members of the board and auditors, and the customary votes of thanks brought the proceedings to a close.

THE CHILDREN'S HOSPITAL, BIRMINGHAM.—The annual meeting of this institution was held on the 25th ult., under the presidency of the Earl of Warwick. The report stated that the number of patients treated during the year was 14,016. The number of in-patients was 922, out-patients 12,987, and casualties 107, being an increase of 402 as compared with the previous year. The amount of air-space in the hospital had been increased by reducing the number of patients, with the result that there was now accommodation for 62 patients with an average of 1040 cubic feet of air per bed, instead of 75 beds with an average of only 875 cubic feet of air. This reduction had not affected the numbers, but only the length of their stay, benefit being received in a shorter time. The accounts were considered, and it was shown that there was an adverse balance of £397 14*s.* 10*d.*, but it was pointed out that a large sum—namely, £1100, had been spent in sanitation of the hospital. Earl Beauchamp was elected President for the ensuing year, and various votes of thanks were passed.

ELECTRICITY FOR THE PRICE OF GAS.—Brighton recently achieved a smart stroke of business in the prompt measures which resulted in the acquisition of the Shoreham waterworks, a stroke which meant practical independence on that score for the town itself and the means to supply more outside customers—of course to the profit of the ratepayers. In the matter of electricity the corporation as suppliers have met with great prosperity. Last year they made a profit much ahead of previous years, and it was said at a meeting of the council last week that in the matter of general use Brighton was ahead of any other town in the kingdom. The balance goes to relieve the general district rate, and the price is lowered. The council decided that the initial charge of 7*d.* per unit for an average of one hour per lamp per day shall be continued and that the charge for electricity over the average should be reduced from 3*d.* to 1½*d.* per unit. This, it is thought, will ensure an adequate net profit, and will make electricity as cheap as gas for heating or motive power. The actual cost of production in the first hour per day is found to be over 7*d.*; after the first hour it is about §*d.* only.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Famine in India.

PAPERS with regard to the famine in India are to be laid before Parliament at intervals of six weeks so long as the famine lasts. These papers will include information as to abnormal mortality occurring within the famine area.

Plumbers' Registration Bill.

There is every prospect of the House of Commons having an opportunity this session of discussing and expressing its opinion by vote upon the Plumbers' Registration Bill. Its promoters were fortunate in the ballot for places, with the result that the Bill stands as the first order on Wednesday, March 3rd.

The Midwives Registration Bill.

The Bill for the Registration of Midwives was introduced in the House of Commons on Tuesday, Feb. 9th, by Mr. de Tatton Egerton, and on that occasion was formally read.

HOUSE OF COMMONS.

THURSDAY, FEB. 4TH.

The Midwives Question.

Mr. Schwann asked the Home Secretary whether the Government proposed to take any action to carry out the report of the Select Committee on Midwives' Registration (of 1893), which was of opinion that a large amount of suffering and death was needlessly inflicted on both women and children of the so-called working classes through the want of medical training amongst those practising as midwives.—Sir Matthew White Ridley, in reply, said he had referred the matter to the Lord President of the Council, who informed him that the Association for promoting the Compulsory Registration of Midwives intend to promote a Bill with this object during the present session, and that he had under consideration the question of receiving a deputation from the Association with regard to it.

Water-Supply in Rural Districts.

Sir Cameron Gull asked the President of the Local Government Board whether his attention had been called to the fact that, although statutory obligations were imposed upon rural district councils in respect of the supply of water to places within their districts, it had been often found practically impossible for those councils to carry out their obligations in the absence of powers of compulsory purchase; and whether, having regard to the serious amount of sickness in country districts which was directly traceable to insufficient or impure water-supply, he could introduce at an early date a short measure enabling rural district councils to compulsorily acquire water rights. Mr. Chaplin said he was advised that there had been cases where district councils had been placed at a disadvantage, and he had already caused the point to be noted as one of the matters which should be considered in connexion with any Bill for the amendment of the Public Health Acts, but for reasons already given on other matters he could not undertake to bring in a Bill this session.

Lunacy Statistics.

Mr. Patrick O'Brien, on behalf of Mr. Corbet, asked the Home Secretary if attention had been recently called to the fact that the number of insane persons under official cognisance in the United Kingdom, Ireland included, have increased from 55,525 in 1862 to 128,896 in 1895, and that the ratio of insane per 1000 of the population had gone up during the same period from 1·81 to 3·28; and whether, in view of the importance of the subject, he would take steps to convene an International Conference to ascertain what measures could be taken to arrest the spread of the disease?—Sir Matthew White Ridley said, in reply: I am aware of the great increase in the number of insane persons in institutions and I would remind the hon. Member that on Feb. 23th of last year I stated in this House that I should consult with the Lord Chancellor with a view to the attention of the Lunacy Commissioners being specially directed to the question. The Lunacy Commissioners have, I am informed, completed a special report on the subject, which is now in the printer's hands; and until I have had the opportunity of considering that report I should prefer not to reply to the second part of the hon. Member's question.

Experiments on Living Animals.

Mr. MacNeill asked the Home Secretary for an assurance that the report for 1896 of experiments on living animals would be published in time for discussion on the Estimates.—Sir Matthew White Ridley said he had already explained why the report of 1895 was issued so exceptionally late, and assured the hon. Member that every effort would be made in future to get the report out on an early date.—Mr. MacNeill then asked what measures were taken in respect to two men licensed to perform experiments on living animals during the year 1895, under the provisions of the 39 and 40 Vic., c. 76, who were stated in the report of the inspector, Dr. G. V. Poore, to have been guilty of irregularities as licensed vivisectors; what were the irregularities brought by the inspector in these cases under the notice of the Secretary of State; were any proceedings under the provisions of the Cruelty to Animals Act, 1876, taken against these persons or either of them; and were the certificates granted to them by the Home Secretary for the purposes of vivisection revoked.—Sir Matthew White Ridley said the irregularities consisted in the one case in the licensee performing an operation on a cat without having the necessary certificate; in the other case in the licensee performing two experiments necessitating a certificate which he had omitted to obtain. In the first case the licence was revoked and was re-granted only after an interval of three and a half months, and steps were taken to prevent a recurrence of the irregularity. In the second case the consideration of the application for a renewal of the licence was deferred for a month. In neither case was it considered desirable to take further proceedings.

The Small-pox Epidemic at Gloucester.

Mr. Chaplin, in reply to a question by Mr. Bayley, said that as the Royal Commission on Vaccination sent a special commissioner to report on the epidemic of small-pox at Gloucester, the Local Government Board did not deem it expedient to instruct their inspector to make a report on the same subject.

Metropolitan Pauper Children.

Mr. Talbot asked the President of the Local Government Board how it was proposed to distinguish between the weak-minded children who were to be entrusted to the care of the new board which was intended to be established in London and the imbecile children at present under the charge of the Metropolitan Asylums Board in their school at Darenth. Mr. Chaplin replied that the children who were sent to Darenth were children in respect of whom the medical officer of the district or workhouse from which they were sent had certified that they were in his opinion chronic and harmless lunatics, idiots, or imbeciles. The distinction in this case would be that children who were of weak or feeble intellect, but were not certified to be imbeciles or idiots, would be subject to the new order

FRIDAY, FEB. 5TH.

Hemp Drugs in the East.

Mr. Chamberlain said, in reply to a question by Mr. Henry J. Wilson, that the Ceylon Government have recently decided, with his approval, to prohibit the importation of hemp drugs into Ceylon and to raise the import duty on opium from one rupee to two rupees per lb.

Experiments on Living Animals.

Mr. MacNeill asked the Home Secretary whether the two men stated in the report of the inspector to have been guilty of irregularities as licensed vivisectors were now in the possession of licences enabling them to perform experiments on the bodies of living animals without anæsthetics, and without being obliged to put the animals to death after the operation; what was the nature of the operation performed by one of these vivisectors before he had obtained a licence; to what penalties did he expose himself by his conduct, and why were not

Hosted by Google

proceedings instituted against him; why were the names of the two vivisectors not published in the report; and would the Home Secretary now declare the names of these persons.—Sir Matthew White Ridley replied: Both the gentlemen referred to now hold licences, one of them with the addition of certificates which enable him to perform experiments without anæsthetics; the other one with the addition of certificates which dispense with the obligation of killing the animal after the effect of the anæsthetic has passed off. As regards the second paragraph of the question, both gentlemen held licences at the time of performing the experiments in question, but had omitted to obtain the certificates which were also necessary under the Act. The experiments in both cases were such as would be allowed, and; in fact, have been allowed, to be performed by properly qualified persons, and both gentlemen had previously the certificates which in the cases in question they had omitted to obtain. The penalties are those provided by the Act of 1876—namely, fine for a first offence and fine or imprisonment for subsequent offences. The irregularities were committed before I came to the Home Office, but I see no reason for dissenting from the opinion of my predecessor, that in the particular circumstances the withholding of the licence for a time and the warning given were sufficient punishment. It was decided on the same grounds not to publish the names, and I am not prepared to do so now.

BOOKS, ETC., RECEIVED.

BAILLIÈRE, TINDALL, AND COX., King William-street, Strand, London.

Practical Manual of Diseases of Women and Uterine Therapeutics. By H. Macnaughton-Jones, M.D., M.Ch. Seventh Edition. Illustrated. 1897. Price 15s.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ALDRIDGE, NORMAN ELLIOTT, M.B., C.M. Edin., D.P.H., R.C.P. & S. Lond., has been appointed Physician to the Royal South Hants Infirmary, Southampton, vice T. W. Trend, resigned.

BRODIE, W. H., M.D. Edin., F.R.C.S. Eng., D.P.H., has been re-appointed Medical Officer or Health for the First and Second Sanitary Districts of the Battle Union.

CLEMMEY, W. N., M.R.C.S. Eng., has been appointed Honorary Surgeon to the Bootle Borough Hospital.

COGHILL, MARY S. SINCLAIR, L.R.C.P. and L.R.C.S Edin., has been appointed Registrar and Anæsthetist to the Royal Hospital for Children and Women, Waterloo Bridge-road.

COOKE, M. A., L.R.C.P. Lond., M.R.C.S., has been appointed Surgeon-Lieutenant in the 2nd V.R. Gloucester Regiment.

CROUCH, H. C., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon and Anæsthetist to the Royal Orthopædic Hospital, London, vice M. H. Sayers, resigned.

CULROSS, JAS., M.B., C.M. Glasg., has been re-appointed a Medical Officer to the Newton Abbot Cottage Hospital.

DAVIDSON, A., M.D. Edin., F.R.C.P. Lond., has been appointed an Honorary Consulting Physician to the Liverpool Royal Infirmary.

DIMMOCK, A. F., M.D. Durh., M.R.C.S., has been re-appointed an Honorary Medical Officer to the Harrogate Infirmary and Dispensary.

DODGSON, R. W., L.R.C.P. Lond., M.R.C.S., has been appointed an Additional Demonstrator on Physiology, St. Mary's Hospital Medical School, London.

ENGLAND, GEO. F., M.D. Camb., M.R.C.S., has been appointed an Honorary Physician to the Royal Hants County Hospital.

EVANS, E. P., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer to the District Council of Mountain Ash.

FERNIE, FRANCIS E., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Swynnerton Sanitary District of the Stone Union.

FOX, EDWARD J., B.Sc. Lond., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed House Surgeon to the Manchester Royal Infirmary.

GRIMBLY, R. H., M.R.C.S., has been re-appointed a Surgeon to the Newton Abbot Cottage Hospital.

HANDFORD, H., M.D., C.M. Edin., M.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health to the Nottingham County Council.

HAYDON, E., M.B., C.M. Glasg., has been re-appointed a Surgeon to the Newton Abbot Cottage Hospital.

HEDGES, JOHN A., M.R.C.S., has been appointed Medical Officer of Health for the Rural Sanitary District of Eaton Bray.

HUNT, E., L.R.C.P. Lond., M.R.C.S., has been re-appointed a Medical Officer to the Newton Abbot Cottage Hospital.

JONES, H., L.R.C.S. Irel., D.P.H. Camb., has been appointed Medical Officer of Health by the Rhondda Urban District Council.

LEES, C. A., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer and Public Vaccinator for the Somersham Sanitary District of the St. Ives (Hunts) Union.

MAGUIRE, ROBERT, M.D. Lond., F.R.C.P., has been appointed a Physician to the Hospital for Consumption, Brompton.

MARGRISON, R., F.R.C.S. Eng., has been appointed an Honorary Surgeon to the Royal Hants County Hospital.

MITCHELL, A. M., M.B., B.C. Camb., has been appointed Resident Medical Officer to Queen Charlotte's Lying-in Hospital, London.

MORRIS, C. D., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer of Health by the Sunbury Urban Council.

NEWTON, LANCELOT, M.R.C.S., has been re-appointed Medical Officer for the Sawtry Sanitary District of the Huntingdon Union.

NISBET, A. T., M.D., C.M. Glasg., has been re-appointed a Medical Officer to the Newton Abbot Cottage Hospital.

OZANNE F. N., L.R.C.P. Lond., M.R.C.S., has been re-appointed an Honorary Medical Officer to the Harrogate Infirmary and Dispensary.

PADWICK, J. C., L.R.C.P. Lond., M.R.C.S., has been appointed a Junior House Surgeon to the Salop Infirmary, Shrewsbury.

PEPPER, A. S., M.S. Lond., M.B., B.S., F.R.C.S., has been appointed a Surgeon to St. Mary's Hospital, London.

POWELL, H. A., M.D., M.Ch. Oxon., L.R.C.P. Lond., M.R.C.S., F.R.C.S. Edin., has been appointed an Honorary Surgeon to the Royal Hants County Hospital.

PULLIN, B. GIBBES, L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed a Surgeon to the Sidmouth Cottage Hospital.

SCOTT, WM. G., M.B. Edin., L.R.C.S., has been re-appointed a Surgeon to the Newton Abbot Cottage Hospital.

SKINNER, STEPHEN, M.B., C.M. Aberd., M.R.C.S., has been appointed Medical Officer of Health for Clevedon, Somerset.

SMITH, L. C., L.D.S.R.C.S. Eng., has been appointed an Honorary Surgeon Dentist to the Durham County Hospital.

SWETE, E. H. W., M.D. St. And., M.R.C.S., D.P.H. Camb., has been re-appointed Medical Officer of Health by the Bromyard Urban District Council.

THORNE, ATWOOD, L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Registrar, Central London Throat, Nose, and Ear Hospital.

TURNER, J. A., M.B., C.M., D.P.H. Camb., has been appointed Medical Officer of Health by the East Herts Urban and Rural District Councils.

VINTER, SYDNEY G., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the Union House and Medical Officer and Public Vaccinator to the No. 2 District, St. Germans Union, vice Charles W. Chubb, resigned.

WATKIN-WILLIAMS, PENROSE L., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed a Medical Officer for the Dunster and Minehead Village Hospital and Deputy Medical Officer and Public Vaccinator for the Dunster District of the Williton Union, Somerset.

WHITAKER, E. T., M.B., C.M. Edin., B.Sc., D.P.H. Camb., has been appointed Medical Officer of Health for the combined Sanitary Districts of Tenbury, Burford, Cleobury Mortimer, and Rock.

WILLIAMS, N., M.B. Cantab., M.R.C.S., has been re-appointed an Honorary Medical Officer to the Harrogate Infirmary and Dispensary.

WOOD, R. E., L.D.S.R.C.S. Eng., has been re-appointed an Honorary Dental Surgeon to the Harrogate Infirmary and Dispensary.

WOOD, W. C., L.R.C.P. Lond., M.R.C.S., has been appointed a House Physician to St. Mary's Hospital, London.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BETHNAL GREEN BOARD OF GUARDIANS.—Second Assistant Medical Officer at the Workhouse and Infirmary, Waterloo-road, Victoria Park, N.E., for six months. Salary at the rate of £80 per annum, with rations, furnished apartments, washing, and an allowance at the rate of £3 per annum in lieu of beer. Applications to the Clerk to the Board, Bishop's-road, Victoria-park, N.E.

BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN.—Resident Medical Officer and Resident Surgical Officer. Salaries £70 and £50 respectively, with board, washing, and attendance at the Institution. Also Extra Acting Physician for three afternoons a week. Salary £40 per annum.

BLACKBURN AND EAST LANCASHIRE INFIRMARY, Blackburn.—Senior House Surgeon. Salary £100 per annum, with board, washing, lodging, &c.

BOLTON INFIRMARY AND DISPENSARY.—Junior House Surgeon, for twelve months. Salary £80 per annum, with furnished apartments, board, and attendance.

BOROUGH OF BURTON-UPON-TRENT.—Medical Officer of Health for the District of the Borough. Salary at the rate of £350 per annum, exclusive of authorised disbursements.—Applications to the Town Clerk, Town Hall, Burton-upon-Trent.

BRISTOL ROYAL INFIRMARY.—Resident Officer, to perform obstetric and other duties, for one year. Salary £40 per annum, with board, lodging, and washing.

CHILDREN'S HOSPITAL, Nottingham.—House Surgeon (non-resident) for six months. Salary at the rate of £100 per annum.

DENTAL HOSPITAL OF LONDON, Leicester-square.—Dental Surgeon.

DERBY COUNTY ASYLUM, Derby.—Junior Assistant Medical Officer. Salary £100, rising to £130 per annum, with furnished apartments, board, &c.

EAST END BRANCH OF THE CHILDREN'S HOSPITAL, Sheffield.—Lady House Surgeon (Out-patient Department only). Salary £70 per annum, with board, lodging, and washing.

EAST SUFFOLK AND IPSWICH HOSPITAL, Thorofare, Ipswich.—A Second House Surgeon, single, for one year. Salary £70 per annum, with board, lodging, and washing.

GENERAL HOSPITAL, Birmingham.—Pathologist, for one year. Salary £100 per annum, with board and residence, £20 per annum being allowed till residence is provided in the new hospital.

GENERAL HOSPITAL, Birmingham.—House Physician, for one year. Salary £70 per annum, with residence, board, and washing.

GREAT YARMOUTH HOSPITAL.—House Surgeon. Salary £90 per annum, with board and lodging, but no wines, spirits, beer, &c., are found.

HOSPITAL FOR WOMEN (THE LONDON SCHOOL OF GYNÆCOLOGY), Soho-square, W.—Clinical Assistants.

JOINT COUNTIES ASYLUM, Carmarthen.—Clinical Assistant for six months. Board, lodging, &c., and honorarium offered.

LINCOLN COUNTY HOSPITAL, Lincoln.—Assistant House Surgeon for six months. An honorarium of £10 and board, residence, and washing.

LONDON COUNTY LUNATIC ASYLUM, Colney Hatch, Middlesex, N.—Junior Assistant Medical Officer, single. Salary £120 per annum, rising £5 a year to £150, with board, lodging, and washing.—Applications to the Clerk, London Asylums Committee Office, 21, Whitehall-place, London, S.W.

LONDON HOSPITAL, Whitechapel, E.—Surgical Registrar. Salary £100 per annum.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Resident Medical Officer, for one year or more. Salary 100 guineas per annum; board, lodging, and washing provided.

MANCHESTER CHILDREN'S HOSPITAL.—Junior Resident Medical Officer, for six months, unmarried. Salary at the rate of £80 a year, with board and lodging. Also Medical Officer for the Dispensary, unmarried. Salary £180 a year, without board or residence.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—House Physician, House Surgeon, Assistant House Physician, and Assistant House Surgeon for six months. The former two will each receive a salary at the rate of £40 a year, and the latter two each at the rate of £20 a year.

PARISH OF ST. GILES, Camberwell.—Assistant Medical Officer for the Infirmary, Havil-street, Camberwell, and the Workhouse at Gordon-road, Peckham; also for Relief Duty at the Constance-road Workhouse of the parish, for one year only. Salary £50, with apartments, board, and washing. Applications to Mr. C. S. Stevens, Guardians Offices, 29, Peckham-road, S.E.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—House Surgeon, for one year. Salary £110, with board and residence.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Examiners.

ST. GEORGE'S AND ST. JAMES'S DISPENSARY, 60, King-street, London.—Physician, and also Physician for the Diseases of Women and Children.

ST. MARY'S CHILDREN'S HOSPITAL, Plaistow, E.—Resident Medical Officer for one year. Salary £80 per annum, with board and washing.

STAMFORD HILL AND STOKE NEWINGTON DISPENSARY, 189, High-street, Stoke Newington, N.—Junior Resident Medical Officer. Salary for the first three months at the rate of £50 per annum, and afterwards at the rate of £75 per annum, with board and residence in each case.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—Professor of Anatomy. Applications to the Secretary and Registrar, University College, Cardiff.

VICTORIA UNIVERSITY—YORKSHIRE COLLEGE, Leeds.—Demonstrator of Physiology. Salary £150.

WEST HERTS INFIRMARY, Hemel Hempstead.—House Surgeon and Dispenser, who shall also be Assistant Secretary, for two years, unmarried. Salary £100 per annum, with furnished rooms, board, fire, lights, attendance, and washing.

Births, Marriages, and Deaths.

BIRTHS.

BARRITT.—On Feb. 2nd, at Welland-terrace, Spalding, Lincolnshire, the wife of G. Lacy Barritt, M.R.C.S., L.R.C.P. Lond., of a son.

BENSON.—On Feb. 2nd, at Fulwood-road, Sheffield, the wife (née Simmonds) of Henry Mitchell Benson, M.B., C.M. Edin., of a daughter.

BUCHAN.—On Feb. 5th, at Athenæum-terrace, Plymouth, the wife of W. A. Buchan, M.B., of a son.

COCKRAN.—On Feb. 3rd, at the Priory, Caversham, the wife of C. H. Cockran, Physician and Surgeon, of a daughter.

GODDARD.—On Feb. 6th, at Wembly, the wife of Charles E. Goddard, L.R.C.P. Lond., M.R.C.S. Eng., of a son.

HUDSON.—On Feb. 6th, the wife of C. E. Leopold B. Hudson, F.R.C.S., of 16, Harley-street, W., of a son.

PETTER.—On Feb. 7th, at Stanhope-road, Darlington, the wife of Walter Petter, M.D., C.M., of a son.

RYLE.—On Feb. 3rd, at Hadley, Barnet, the wife of Reginald John Ryle, M.D., of a daughter.

TOWNSEND.—On Feb. 3rd, at Ivy House, Normanby, the wife of F. E. Townsend, M.D., of a son.

VOELCKER.—On Feb. 6th, at Harley-street, the wife of Arthur F. Voelcker, M.D., of a daughter.

MARRIAGES.

MACLAURIN—CROAL.—On Feb. 4th, at Sydney, Charles MacLaurin, M.B., C.M. Edin., eldest son of the Hon. Henry Norman MacLaurin, M.D., LL.D., Chancellor of Sydney University, to Anne Bithiah (Nannie), fourth daughter of Thomas Allan Croal, 16, London-street, and General Post Office, Edinburgh.

MARSH—BAQUERA.—On Feb. 3rd, at the Garrison Church (King's Chapel), Gibraltar, Surgeon-Major T. A. Perry Marsh, Army Medical Staff, youngest son of the late H. G. Marsh, J.P., of Winterbourne, Glos., to Cecilia de Baquera, second daughter of Don Nicente Baquera, of Malaga, Spain.

TINLEY—LEA.—On Feb. 3rd, at Christ Church, Bridlington Quay, William Edwyn Falkingbridge Tinley, M.B., M.R.C.S., elder son of Thomas Tinley, M.D., J.P., of Hildegard House, Whitby, to Ada, younger daughter of Thomas Lea, of Abbey-terrace, Whitby.

DEATHS.

BOURNE.—On Feb. 7th, at 5, Pittville-crescent, Cheltenham, Walter Bourne, M.D., aged 68.

BROWN.—On Feb 7th, at Shaldon, Devon, Osmond Percy Brown, M.R.C.S., L.S.A., aged 35.

FRENCH.—On Feb. 9th, at his residence, Darmstadt, Sutton, Surrey, suddenly, Henry French, M.R.C.S., aged 83.

SHARPLES.—On Feb 8th, at his residence, Maisonnette, Leam-terrace, Leamington, William Sharples, M.R.C.S., in his 84th year.

SHEPHERD.—On Jan. 24th, at Bloemfontein, Orange Free State, Ernest Shepherd, M.R.C.S., L.R.C.P., aged 26.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (16th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (17th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30P.M.).

THURSDAY (18th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.)

FRIDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (20th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (15th).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. F. de Havilland Hall: Disease of the Nose and Throat in Relation to General Medicine. (Lettsomian Lecture.)

TUESDAY (16th).—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Papers:—Dr. T. C. Fox and Dr. F. R. Bloxall: The Plurality of Ringworm Fungi (with lantern demonstration).—Mr. S. G. Shattock: Undescended Testicle Removed in Radical Cure of Hernia.—Dr. H. M. Fletcher: A Congenital Cyst of the Mediastinum.—Dr. F. J. Wethered: Case of Hypertrophy of the Lung. Card Specimens:—Mr. J. Poland: Cylindrical-celled Carcinoma of Testis.—Dr. F. J. Smith: Aneurysm of the Thoracic Aorta in a Boy.

ROYAL STATISTICAL SOCIETY (Royal United Service Institution, Whitehall, S.W.).—5.30 P.M. Mr. N. A. Humphreys: English Vaccination and Small-pox Statistics, with Special Reference to the Report of the Royal Commission and to recent Small-pox Epidemics.

WEDNESDAY (17th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Mr. G. M. Giles: On a Simple Method of Micro-photography.

THURSDAY (18th).—SOCIETY OF ANÆSTHETISTS (20, Hanover-square, W.).—8.30 P.M. Casual Communication by Mrs. Dickinson Berry, M.D. Lond. Paper:—Dr. L. Hill: The Causation of Chloro form Syncope, an Experimental Enquiry.

HARVEIAN SOCIETY.—8.30 P.M. Prof. H. R. Spencer: On the Diagnosis and Dangers of Breech Presentation, and its Treatment by External Version during Pregnancy.

FRIDAY (19th).—EPIDEMIOLOGICAL SOCIETY OF LONDON (11, Chandos-st., Cavendish-sq.).—8 P.M. Meeting.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (15th).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. W. R. H. Stewart: Examination of the Ear.

ROYAL COLLEGE OF SURGEONS.—4 P.M. Mr. C. Heath: Hunterian Oration.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Mr. A. Wynter Blyth: Introductory Lecture, on Factory Legislation.

TUESDAY (16th).—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Mania, Acute, Hysterical, Acute Delirious.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Payne: Eczema, its Varieties.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Dr. D. Grant: The Diagnosis and Treatment of Diseases producing Pain in or about the Ear.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Ferrier: Lecture.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street).—4 P.M. Dr. T. D. Savill: Cases of Hysteria.

WEDNESDAY (17th).—LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-street, W., 4.30 P.M., Prof. A. Wynter Blyth: Refuse Removal and Disposal.

HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Dr. Wethered: Hæmoptysis.

THURSDAY (18th).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: On the more important Constituents of Normal Urine.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. J. Hopkins: Clinical Lecture.

SOCIETY OF ARTS.—8 P.M. Prof. J. A. Ewing: The Mechanical Production of Cold. (Howard Lecture)

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Mr. H. Mauley: Sanitary Law, English, Scotch, and Irish; General Enactments Public Health Act, 1875; Model Bye laws, &c.

FRIDAY (19th).—LONDON POST-GRADUATE COURSE.—Kings's College, 3 to 5 P.M., Prof. Crookshank: The Microscope and Methods of Cultivation.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Mr. W. Van Praagh: Defects of Speech.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Taylor: Jacksonian Epilepsy.

THE CANCER HOSPITAL (FREE) (Fulham-road, Brompton, S.W.).—4 P.M. Mr. H. Snow: The Value of "Anticipatory" Gland Excision in Cancer-Surgery.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index for the second volume of 1896 was given in the issue of Dec. 26th last. The practice of supplying loose copies has been discontinued, the Index having been placed in the centre of the journal, whence it can easily be detached, and placed either at the beginning or at the end of the volume.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1896 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.* (Local bookbinders will charge about 1*s.* for binding the numbers in these cases.)

To be obtained on application to the Manager, accompanied by remittance.

LANTERN LECTURES.

To the Editors of THE LANCET.

SIRS,—Would any of your readers who have given popular lectures on hygiene and have illustrated them on screens with lamps, kindly let me know the cost of the hire of the whole apparatus and where obtainable.

I am, Sirs, yours truly,

Feb. 8th, 1897. HYGIENIST.

"A CRUISE ON A WHALER."

To the Editors of THE LANCET.

SIRS,—Noticing an inquiry in THE LANCET of Jan. 30th as to obtaining a berth as surgeon to a whaler I am induced to offer you a few remarks. I possess, I believe, the distinction (?) of being surgeon to the last sperm whaler out of England. The *Cowlitz*, to which I refer, left in 1856 returning to England in the autumn of 1859. The surgeon has a fairly rough time of it, having to go aloft daily regularly on the lookout, and is held responsible for the safety of the boats when away from the ship after whales, not a nice job in squally weather or when the boats are away after sundown and the lights of glimmering lanterns have to be kept sight of, with only four boys to work the ship, which is necessarily under easy canvas. He has also to take an occasional spell at boiling oil. Of course, among the South Sea islands the weather is intensely hot. I know nothing as to the black or Greenland whalers, but I saw what I believe was the last of them come into Dundee some four years since when taking a summer holiday. The Americans still do a little from San Francisco, and there are small vessels from Sydney which are only away a few months on a trip. Oil, both sperm and black, is of comparatively little value, and the trade, I fancy, as far as England is concerned, is extinct.

I am, Sirs, yours truly,

Feb. 7th, 1897. F. E. BARNES, M.R.C.S.E., L.S.A.

C. T.—We have replied to the question previously in these columns. We think that the notifications should be stamped.

WINTER RESORTS.

DR. P. C. HICKEY, of Kilkee, co. Clare, writes to us calling attention to the salubrity of the climate and its beneficial effect in cases of irritable throat or mild stages of phthisis. The town "is also a fine sanatorium for convalescents from the effects of surgical operations and debilitating diseases such as whooping-cough, Bright's disease, and the various forms of exanthemata. ..... Frost is seldom seen, snow is a rare event, and fogs are unknown. Of the great snow-storm which swept England and Ireland on Jan. 21st and 22nd we have had no evidence except the reports in the daily papers. Kilkee is built round a very small sheltered bay facing the Atlantic, upon a narrow tongue of land averaging a mile or a mile and a half in width, and stretching to the southwest between the ocean and the great estuary of the river Shannon for about sixteen miles. It is, as it were, a ship at sea, therefore the climate is equable. The soil is light and sandy, rain dries almost as it falls, and the Gulf Stream flows close to its shores." Kilkee has direct railway communication with Dublin. It has good hotel accommodation at very moderate prices, and there are two trout rivers within six miles; there is also first-rate sea fishing and the principal hotel has rights of shooting over preserved ground.

Mr. T. WHITEHEAD writes:—"It may interest your readers to learn that while the majority of our watering places have experienced some severe weather this winter yet Bude has been fortunate in having had but little frost and no snow or fog. There are still some stocks and violets in bloom in my garden, and though we have had some cold easterly winds, yet is has always been possible to get out for walks on the sands or cliffs. Rain falls on fewer days in the year at Bude than at any other seaside place, Bournemouth excepted, where the number of rainy days in the year averages 149, Bude making a good second with 150 only. I may add that the temperature is only two-tenths of a degree below Torquay, and that the railway between Holsworthy and Bude is in course of construction and will be completed in about twelve months, so that the ten miles coach drive, always a dreary part of the journey in winter, will soon be a thing of the past. We have a grand sea, fine cliffs, and bracing climate, and your readers might do worse than to give Bude a trial for winter or spring."

Disgusted.—The paragraph is certainly quite wrong and a gross offence against accepted canons of etiquette. But has our correspondent any proof that the gentleman whose name is so prominently brought forward knew anything about the insertion of it previously to its appearance in print?

L. H. C.—It would not be right to insert the change of address in the lay papers of the district into which the move is being made. In unprincipled hands such an act would become at once an invitation to the public to rally round the new practitioner.

"HYPODERMIC MEDICATION."

To the Editors of THE LANCET.

SIRS,—In answer to "Regular Reader" in THE LANCET of Feb. 6th, I can say that the most convenient hypodermic syringes I know of are made of celluloid by Mousnier, 26, rue Houdan Sceaux, Seine, France. They are perfectly aseptic on account of the material they are made of; they never require to be asepticised—passed through a flame, &c.—as glass or metal ones. I have had them in continuous use for over four years. I wish to say, further, that the fluid medicines are kept in celluloid tubes; they keep perfectly aseptic.

I am, Sirs, yours faithfully,

Geneva, Feb. 7th, 1897. A. CORDES, M.R.C.P. Lond.

TREPHINING THE FRONTAL SINUSES.

To the Editors of THE LANCET.

SIRS,—Trephining the frontal sinuses is by no means a new surgical operation nor is it infrequently performed, but too often we do not see the patient until a nasty external sinus has been formed. The following interesting case came under my care at the London Throat Hospital towards the end of 1895. The patient, a woman, came complaining of inability to breathe through the right nostril accompanied by a distressing discharge. The difficulty in breathing had come on, gradually increasing, during the last eighteen months; the discharge had lasted for quite five years. On examination the nostril was found full of large polypi and when these were removed the discharge was found to be as bad as before and pus was clearly seen flowing from the infundibulum. It was determined to open the frontal sinus, and this was done with a small trephine a few days later. The sinus was found full of web-like granulation tissue, in which three small mucous polypi were embedded. The whole of this tissue was carefully scraped out. A small drainage-tube was put in with the object of keeping the wound open for the necessary time. The sinus was well syringed out through the wound with the biniodide of mercury solution (1—1000) each day until the lotion came freely and quite clear into the nose. On the 8th day the drainage-tube was removed and the wound quickly healed up. With the operation the discharge ceased and has not returned since. I saw this patient last November, a year after her first coming to the hospital and nine months after the operation, when she still remained quite free from trouble.

I am, Sirs, yours faithfully,

Devonshire-street, W., Jan. 25th, 1897. GRIFFITH C. WILKIN.

Cerium.—"Golf arm" is somewhat of the same nature as "lawn-tennis arm." Probably the injury consists in a strain or rupture of some of the ligamentous and muscular fibres (particularly of the supinator brevis) around the elbow joint. Very likely, too, the posterior interosseous nerve is involved.

Nurse Stewart will obtain all information from the Secretary of the National Society for the Employment of Epileptics, Hanover-chambers, 12, Buckingham-street, Strand.

R. W. S.—The last Students' Number of THE LANCET was issued on Sept. 5th, 1896, and contains a full account of all that our correspondent wishes to know.

J. R.—We cannot recommend individual practitioners.

THE GENEROSITY OF A NAVAL CAPTAIN.

WE have received a letter from Captain Gallet of East Dulwich in which he desires to make through our columns the following handsome offer:—

> "I offer to any university, doctor, or private person," he writes, concerning consumption, "to demonstrate by irrefutable proofs after experiences will have been made upon people suffering from that disease, that by a treatment which I shall subject them to, I can radically cure them, on the condition that the patient is not in the last stage of the illness. ..... I have also a remedy for the cure of external cancer or gangrene, which illness I have cured myself, and for dysentery (from which I saved eighteen of my sailors at Santiago de Cuba). All these remedies can be easily obtained, and I hold them at the disposal of the Government if they wish it for their expedition to Benin, and I guarantee that with them they will not lose one man by disease of the above-named natures. *Cholera.*—I have been fighting against that illness during the Crimean war, and I possess a certificate that will prove what I did and how my remedies acted."

Shall we be considered narrow and prejudiced if we warn the gallant captain to mind his own business and to abstain from deluding the sick with idle promises? We are willing to believe that he can step a horn-pipe, box a compass, or lead a cutting-out expedition with any nautical hero afloat. But, avast there! If the history of the Crimean War formed one long pæan in Captain Gallet's praise, we should none the less hold him a mischievous person when he took to quackery.

C. P., F.R.C.S.—We have already had our attention called to this matter. There is no evidence that the medical man in question knew anything about the insertion of his name, and everyone who knows him must be aware that he is the last man to countenance such a method of obtaining publicity.

Leges.—The possibility of the occurrence is so well known that authorities cannot be necessary to prove it. If the persons are physically perfect their consanguinity would be no bar.

THE CAUSATION OF SEX.

A CORRESPONDENT, who writes on the above subject, probably refers to a letter in THE LANCET of May 7th, 1881, page 769. If he will consult "Neale's Digest" he will find that numerous references to the subject have appeared in our columns, extending from the year 1870 to 1894.

Hosted by Google

"ANTISEPTIC MIDWIFERY."

To the Editors of THE LANCET.

SIRS,—I was much interested in the address of Dr. Clement Godson on the above subject in THE LANCET of Jan. 23rd, 1897, owing to the fact that in the early part of 1887 I copied from the 1886 edition of Playfair's "Midwifery" the following note and pasted it on the inside of my instrument case, from which I now transcribe:—

"Antiseptic Midwifery" { Acid. Carbol. 1 in 50. / Tinct. Iodi diluted to pale sherry colour. / Condy 1 in 80. / Hydrarg. perchlor. 1 in 2000—best."

Finding the sublimate described as the best I choose it first and have used it in every case since then—as a vaginal injection in normal labours, and intra-uterine where the hand, forceps, &c., has entered the uterus—with the result that, with one exception, in no case where I have been present at the confinements has puerperal septicæmia followed. The exception was in the case of a primipara, aged eighteen years, the wife of a cavalry soldier, who, without my knowledge, had used a waterproof sheet which he had taken from the stable. I had it instantly removed and the bed changed and recovery was uneventful. At no time have I had any symptoms of mercurialism; this I attribute to careful expression of the contents of both uterus and vagina after injecting. In one part of his address Dr. Godson says, "Why the sublimate treatment should not be adopted in private practice as well as in hospitals I am at a loss to understand." Is this assumption correct? As far as I am aware it is a very general treatment in private practice.

I am, Sirs, yours truly,

Ballincollig, Jan. 26th, 1897. JAMES J. HARDING.

W. B. W.—We are unable to say at present whether there is any definite expectation of the drug mentioned being able to keep the particular disease in check. Reports on the matter are very conflicting.

THE SILENT COAL BOX.

AMONG the many trifles which go to make up perfection in the sickroom none is more important than absence of noise, and nothing is more irritating to a sick person than the noise which attends the operation of putting coals on the fire from an ordinary coal box, which in the quietness of the sick room seems to have been specially constructed as a sounding box from which to obtain the maximum of noise from the minimum of space. More than one inventor has attempted to construct a really silent coal box but perfection is far from having been attained, and the articles put before the public, though more expensive, are little better in practice than the common expedient of placing pieces of coal wrapped in thick soft paper in a paper- or india-

rubber-lined wooden box lid or papier maché tray with a pair of small muffled tongs for a lifter. The article of which we give an illustration is manufactured by Messrs. Reynolds and Branson of Leeds, and is made of cowhide. A pair of tongs covered with india-rubber tubing are supplied for lifting the coals from the box. We have practically tried the invention, and although it is perhaps more convenient and gives less trouble than the expedients mentioned above, the amount of noise is not perceptibly lessened. For a really efficient sickroom coal box it is not only necessary that the material of which the box is composed should be non-resonant, but the coals contained in the receptacle must also be prevented from falling together to take the place of pieces removed. The price of the apparatus is £1 5*s.*

Justitia.—Yes, the duty is at ninepence in the pound. The house in question is not a place where goods are exposed for sale.

Canthos.—The recognised custom in the civil profession is for the newcomer to call, but our correspondent need not do so unless he desires.

A QUERY.

To the Editors of THE LANCET.

SIRS,—Is it possible for pieces of placenta, membrane, or blood clot retained in the uterus after delivery to set up symptoms of puerperal fever? And, if so, do the symptoms differ from those cases in institutions which had a mortality of 1 in 19?

I am, Sirs, yours truly,

Feb. 10th, 1897. ANTISEPTIC MIDWIFERY.

*** Certainly, it is quite possible to have symptoms of "puerperal fever" set up by portions of placenta or clot retained in utero. The mortality of such cases depends on the treatment adopted.—ED. L.

STRAIGHT FROM THE COW.

To the Editors of THE LANCET.

SIR,—During an attack of dysentery I was advised to take milk-and soda-water. I found that milk warm from the cow was more beneficial. Is there any sucker arrangement to attach to a cow's udder by which milk can be drawn off and sucked through a tube without being exposed to the air at all? If delicate, growing children, and invalids would take milk in this way, it would do them far more good than milk (especially boiled milk) which has been exposed to the air. Have wet nurses ever given their services to invalids? If not, why not?

I am, Sir, yours truly,

Rangoon, Burma, Jan. 1st, 1897. WEAK STOMACH.

Liber will find in our Students' Number, which was published on Sept. 5th, 1896, at pages 652, *et seq.*, a very complete list of the best text-books. The two treatises of medicine he mentions are not comparable. We recommend him to reinforce his study of Hilton Fagge's work by reference to special articles in Dr. Clifford Allbutt's System of Medicine.

Alpha.—Inhalation is practised with different drugs for different diseases in their different stages, but we know of no treatise dealing with its therapeutics exclusively.

A PROPOSED CRIPPLES' AID UNION.

MR. GILLINGHAM, of Chard, Somerset, whose ingenious appliances for artificial limbs, &c., we have previously noticed favourably in our columns, has sent us a proposal for the celebration of Her Majesty's record reign. It is that a national provincial cripples' aid union should be formed for the relief of those crippled by accident or disease. Centres of this union should be formed, he thinks, in every large centre of industry, and committees formed for the rural districts. We would make an addition to our correspondent's suggestion, and say that if this proposal is ever carried out the present Surgical Aid Society should be invited to act as the trustees of the parent fund of this union. Mr. Gillingham's suggestion is, we think, a good one and might be usefully acted upon.

Mr. P. S. Oram.—We do not know of any special authority on the subject, but are confident that our correspondent could obtain a sound opinion on the question from any leading consultant in his city.

Mr. Henry Pilkington is thanked for his communication.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

The Hunterian Oration.

Delivered at the Royal College of Surgeons of England on Feb. 15th, 1897,

BY CHRISTOPHER HEATH, F.R.C.S.ENG.,
PAST PRESIDENT OF THE COLLEGE; HOLME PROFESSOR OF CLINICAL SURGERY IN UNIVERSITY COLLEGE, LONDON; AND SENIOR SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

[AFTER some introductory remarks Mr. Heath said that previous Hunterian Orators had laid stress on the fact that John Hunter was a learned physiologist and a profound pathologist but had in some measure ignored the fact that he was also a great surgeon, and it would be his effort that day to set out this side of Hunter's character. He mentioned Hunter's apprenticeship to his brother-in-law Buchanan, when he acquired manual dexterity by working as a carpenter, his work as assistant to his brother William, when he trained his hand as a dissector, his work under Cheselden and Pott, his house surgeoncy at St. George's, and his short though important career as an army surgeon. Passing on to Hunter's return to London in 1763, the orator referred to the election to St. George's as surgeon in 1768 and to his course of lectures on the "Principles of Surgery," which commenced in 1774. Mr. Heath continued:—]

In his lecture on "Injuries of the Head," Hunter shows himself to be far in advance of his contemporaries, with whom trephining the skull was a matter of routine. He says: "In cases of fissure of the skull only it may admit of dispute whether we are always to trepan. If there is no symptom of an injured brain, certainly it will not be necessary. It may not be necessary even when attended with symptoms of an injured brain, for the injury may only be from the concussion, and we never trepan for concussion." Again he lays great stress upon the danger of opening the dura mater because of the occurrence of fungus cerebri, which was almost constant before the introduction of antiseptic dressings, and even now is not entirely unknown. He says, "whenever I have seen the dura mater opened the brain has worked through the opening, and the patients have died. This was the case with a Mr. Cooper, whose dura mater I opened with a crucial incision on account of the state of the parts beneath; he died, and I think it is probable I killed him by opening the dura mater." Mark the honesty of the man—"it is probable I killed him." Fashion reigned in Hunter's time as at present. Thus under the head of simple fracture we find him saying, "the position for the patient to lie in was formerly on the back, but the side is now generally adopted. However, I think its whole advantage is that it has the appearance of novelty, and is not a real improvement; but time will establish the truth." Again, in speaking of fractured patella, he says, "Before the year 1750 it was the practice to endeavour to bring the broken ends of the bones as near together as possible, with little or no motion allowed; but after that a fashion arose (for we have fashions in surgery as in everything else, arising perhaps from a person happening to do well who had not been treated in the old way) of letting the parts separate, and of not forbidding motion so strictly; but now caprice has, I believe, had its day, and we are taught by reason and experience that the parts should be, when cured, as nearly as possible in their natural situation."

Here, thanks to Mr. D'Arcy Power, I am able to avail myself of a little bit of contemporary criticism in the form of an "Essay on the Fracture of the Patella or Knee-pan, by John Sheldon, F.R.S., Professor of Anatomy in the Royal Academy of Arts, London, 1789." Mr. Sheldon combats the view that the extension of the leg relaxes the muscles attached to the patella, though, as he says, "those anatomists whose opinions I am acquainted with, as the late Dr. Hunter, Mr. J. Hunter, the late and present Professor Monro, and every other teacher or writer I have seen or heard of, have entertained the same opinion, though the contrary is evidently the case." He proceeds to argue that the thigh must also be flexed upon the pelvis, a practice which has been generally adopted for many years, so as to relax the rectus; but he also recommends slight flexion of the knee so as to relax the hamstrings—a useless and harmful proceeding.

In his lecture Hunter tells the story of a lady with an old fractured patella and great separation of the fragments, with consequent loss of power; and Sheldon speaks with approval of his plan of exercising the muscles of the thigh, by swinging the leg with weights attached to the foot. How both these surgeons would have appreciated my colleague Mr. Barker's simple plan of wiring the fragments together by the sub-cutaneous method!

John Hunter's name is so inseparably connected with the treatment of aneurysm that it is almost unnecessary for me to maintain his claims to originality in his operation of applying a ligature at a distance from the sac, particularly after the exhaustive lectures on the subject of aneurysm which were given in this theatre in 1871–3 by Mr. Holmes. The claims put forward by French surgeons, and particularly by Broca in his classical work on aneurysms, for Anel as the proposer of the Hunterian operation will not bear investigation; for it is clear that Anel really placed a ligature above the aneurysm, and in close proximity to it, and only differed from his predecessors in not laying open the sac. It is well known that this method and its varieties proved so fatal from secondary hæmorrhage that Pott, the leading authority of the day, recommended amputation as the only safe proceeding; and on this Hunter remarks in his lectures, "When the disease is in an advanced stage I agree with Mr. Pott in thinking amputation necessary and preferable. The earlier, therefore, the operation for the aneurysm is performed the better, not waiting with the expectation that an increased size of the aneurysm will produce an increased size of the collateral branches. If the artery, however, cannot be tied above the aneurysm in the operation, where can it be tied if the limb be amputated? Why not tie up higher in the sound parts where it is tied in amputation and preserve the limb?"

The first operation performed by Hunter for popliteal aneurysm, by ligature of the femoral artery in Hunter's canal, was in December, 1785, the patient being a coachman aged forty-five years. Sir Everard Home gives full details of the case in the *London Medical Journal*, vol. vii., 1786, and vol. viii., 1787, and also in the first volume of the Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge, which was published in 1793, during Hunter's lifetime. It is quite clear that the vein was included in the ligatures, which were four in number, two being tied and two kept in reserve. The patient recovered. Home gives four other cases operated on by Hunter, one of which was fatal; and on the fourth case it is remarked that "in performing the operation the vein was not included in the ligature," implying that previously the vein had been so included. In the museum of this College is preserved the preparation of this historical case (3258)—obtained by Hunter "with some trouble and considerable expense" on the patient's death, fifteen months after the operation—a drawing of which accompanies Home's second paper in the *London Medical Journal*, 1787. "The femoral artery was impervious from its giving off the arteria profunda as low as the part included in the ligature. Below this part the femoral artery was pervious down to the aneurysmal sac and contained blood, but did not communicate with the sac itself, having become impervious just at the entrance. What remained of the aneurysmal sac was somewhat larger than a hen's egg, but more oblong and a little flattened. It contained a solid coagulum of blood, which adhered to its internal surface. A section made of this coagulum appeared to be composed of concentric laminæ, uniform in colour and consistence. The trunk of the femoral vein where it passed along the side of the tumour must have been obliterated." Appended to the account of the dissection is the following remark:—"The conclusion to be drawn from the above account appears a very important one, viz., that simply taking off the force of the circulation from the aneurysmal artery is sufficient to effect a cure of the disease, or at least to put a stop to its progress, and leave the parts in a situation from which the actions of the animal economy are capable of restoring them to a natural state." We are not informed whether this statement of Home had the support of Hunter or not, but it is a little remarkable that no reference should have been made to the collateral circulation, which has such an important bearing upon the formation of laminated clot within an aneurysm.

Hosted by Google

Our museum contains also, thanks to the late Mr. Thomas Wormald, the specimen from Hunter's fourth case, in which the vein was not included in the ligature. The patient was thirty-six years old and survived the operation for fifty years. "The portion of artery obliterated by the ligature extends from the origin of the profunda downwards to the division of the popliteal. A small oblong mass of earthy matter occupies the situation of the aneurysm."

Of course, Hunter's new operation had a certain amount of opposition, notably from his colleague Bromfield and from Percival Pott; but we find in Home's paper that Mr. Lynn, of the Westminster Hospital, had a successful case, the date of which is not given. Hunter was cursed with a candid friend, one Jesse Foot, surgeon, who published the year after his death "The Life of John Hunter," in which he criticised severely the whole of Hunter's professional career; but it is remarkable that he makes no allusion to the operation for aneurysm.

Of the separate volumes which Hunter published the first was that on "The Natural History of the Human Teeth" and a "Practical Treatise on the Diseases of the Teeth," price £1 1s., 1778. The late Mr. Thomas Bell, F.R.S., himself a distinguished dental practitioner, as well as for many years Lecturer on Comparative Anatomy at Guy's Hospital, in the preface to Hunter's essay in Palmer's edition, speaks of the work thus: "If it may be stated that the work in question is perhaps the least felicitous effort of this extraordinary genius, and that of which the errors are the most obvious and striking, some apology may be found even for these in the confined nature of the subject and especially in the obscure and anomalous structure of the organs of which it treats; whilst the basis which his experiments and observations have laid for subsequent improvements in our knowledge, both of the physiology and pathology of the teeth as well as in the treatment of their diseases, constitutes a never-ceasing claim to the gratitude and admiration of every scientific practitioner of dental surgery."

Mr. Jesse Foot, surgeon, in "The Life of John Hunter," already mentioned, does not spare the author, but devotes no fewer than thirty pages to a detailed criticism of this work on the teeth, interspersed with remarks of a more or less scurrilous nature. Mr. Foot says, no doubt with truth, "John Hunter, at the time he published this book, had but very little practice, the whole circle being then filled up by names to which I have before alluded; and Hawkins, Bromfield, Sharpe, and Pott were proud and unaccommodating professional men. They were above submitting to consultations with dentists. Their patients, who wanted advice for relative complaints of the teeth, sent for or went to them, and from them took the instructions which the dentists were to obey. Hunter laudably condescended to accommodate himself to the necessity of the case, and to fill up this chasm in practice he placidly attended on fixed days and hours at the house of a dentist to aid him by consultation for the benefit of his patients." In Chapter IX., which treats of Drawing the Teeth, Hunter has to his caution against rapid extraction of the teeth appended the following note: "I must do Mr. Spence the justice to say that this method appears to be peculiar to him and that he is the only operator I ever knew who would submit to be instructed or even allow an equal in knowledge, and I must do the same justice to both his sons." Mr. Foot thereupon says: "John Hunter was not found to bestow his smiles upon every dentist; his sincerity in friendship confined him alone to the family of the Spences"; and then proceeds to give a personal recollection of the elder Spence dating from 1762, when he kindly extracted without fee a tooth from Mr. Foot, who was then an apprentice.

No doubt, as Bell has pointed out, Hunter made mistakes in his work on the teeth, particularly as regards the development of the second set and their relation to the temporary teeth. But the sections on gumboils, on excrescences from the gum, on deeply-seated abscesses in the jaws, and on abscess of the antrum maxillare show that he had considerable experience in the ailments connected with the teeth and their surgical treatment. His chapter on "Transplanting Teeth" shows how careful he was in dealing with all the details of such a delicate operation, which we know to have been highly successful in his hands, although eventually abandoned on account of the fear of transmitting syphilis.

In 1786 John Hunter published "A Treatise on the Venereal Disease," which excited a good deal of controversy at the time and has been freely criticised during the last fifty years. Hunter had no doubt seen a great deal of venereal disease whilst serving with the army both at home and abroad, though he seems to have ignored to a very great extent the labours of others in the same field of inquiry. His reputation as an anatomist and surgeon was so great that the work was received both at home and abroad with acclamation. In 1787, the year after publication, French and German translations appeared. In 1788 there was a second English edition, and in 1791 the first American edition was published. There were not wanting, however, contemporary critics, and foremost amongst them must be mentioned Benjamin Bell of Edinburgh and Mr. Jesse Foot, surgeon, to whom I have already referred. This last gentleman brought out a volume of 450 pages, in which he goes *seriatim* through Hunter's work, criticising as far as possible all his statements and speaking of him invariably as the "Professor," which he seems to regard as a term of reproach. Unfortunately, Hunter started with the idea that the poisons of gonorrhœa and syphilis were identical, and so early as 1767 made experimental inoculations upon himself with gonorrhœal matter, as he believed, but which, no doubt, was mixed with the discharge from a chancre within the urethra. A chancre and secondary symptoms resulted, for which mercury was taken, and, in his own words, "the time the experiments took up from the first insertion to the complete cure was about three years." After such a personal experience it is not surprising to find Hunter laying down explicitly: "The experiment proves that matter from a gonorrhœa will produce chancres." His critic, Foot, takes the same view, and says sarcastically: "I shall be glad to be informed by the Professor who ever doubted but that it [the poison] was the same!" It is the more curious that such an acute observer as Hunter should have fallen into such an error, for we find him laying down that "till about 1753 it was generally supposed that the matter from the urethra in gonorrhœa arose from an ulcer or ulcers in that passage, but from observation it was then proved that this was not the case." He proceeds also to show, by the examination of the bodies of criminals known to be the subjects of gonorrhœa at the time of execution, that the prevailing belief in the existence of warts or growths in the urethra in all cases of gonorrhœa was incorrect. Hunter seems to have had undoubting faith in the contradictory statements of his patients, and particularly of his female patients, the subjects of gonorrhœa. It is difficult otherwise to understand the conclusions he comes to, for they often appear to be entirely opposed to modern experience. His views also on swelled testicle do not commend themselves to the modern surgeon, for he held that the inflammation was due to "sympathy," and that the testicle "is never affected with the venereal disease, local or constitutional." However much in the present day we may disagree with Hunter in recommending a mercurial course for the treatment of gonorrhœa we must allow that he thoroughly appreciated the various affections of the urinary organs which commonly result from and follow that disorder. Still more valuable are the chapters on "Supposed Consequences of Gonorrhœa," disorders which have proved a happy hunting ground for the quack for many generations. Hunter's description "of the discharge of the natural mucus of the glands of the urethra" is brief but forcible: "The small glands of the urethra and Cowper's glands secrete a slimy mucus similar to the white of an egg, not coagulated. This seldom appears externally or flows from the urethra but during the indulgence of lascivious thoughts, and is seldom or never attended to except by those who are either under apprehensions of a gonorrhœa coming on, or imagine the last infection is not gone off entirely, and are therefore kept in constant terror by this natural discharge." He then passes on to speak of "the discharge of the secretions of the prostate gland and vesiculæ seminales," and expresses a strong opinion, in which modern physiologists agree, that the vesiculæ are not seminal receptacles. "It is a discharge of mucus," he says, "by the urethra which generally comes away with the last drops of urine, especially if the bladder is irritable, and still more at the time of being at stool, particularly if the patient be costive, for under such circumstances the straining or action of the muscles of these parts is more violent. It has generally been supposed that this discharge is semen, and the disease is called a seminal weakness; but it appears from many experiments and observations that the discharge is undoubtedly not semen." So highly do I appreciate John Hunter's good common-sense teaching on this important

Hosted by Google

subject that I have for many years kept this page in his works doubled down in order that I may read out an authoritative statement to those miserable persons who consult the surgeon from time to time for so-called "spermatorrhœa"—a word which one could wish eliminated from our language.

It is remarkable that the term "Hunterian chancre" should have been the universally accepted description of the primary syphilitic sore, for Hunter himself says: "Venereal ulcers have one character, which, however, is not entirely peculiar to them, for many sores that have no disposition to heal (which is the case with a chancre) have so far the same character. A chancre has commonly a *thickened base;* and although in some the common inflammation spreads much further, yet the specific is confined to this base." But what is most remarkable is that Hunter denied the existence of chancres on the mucous membrane of the vagina or cervix uteri, and *a fortiori* did not recognise such unusual occurrences as chancre of the lip, &c. Although the anatomy and pathology of the lymphatic system, including glandular enlargements, had made great progress during the previous century, yet the primary indolent bubo was not recognised as typical of syphilitic infection. Thus we find Hunter describing all kinds of buboes as occurring during the primary stage of syphilis, and even advocating the mercurial treatment of suppurating chancres and inflamed buboes.

From what has been already said it cannot surprise us to find Hunter's views of the lues venerea or constitutional syphilis little in accordance with the opinions of the present day. It will be sufficient to quote the following as regards the transmission of syphilis from parent to child. "It is supposed," says Hunter, "that a fœtus in the womb of a pocky mother may be infected by her. This I doubt very much. However one can conceive the bare possibility of a child being affected in the womb of a pocky mother—not, indeed, from the disease of the mother, but from a part of the same matter which contaminated the mother." Again, he says: "It has been supposed that such a contaminated child could contaminate the breasts of a clean woman by sucking her," and yet a little later he describes vividly enough the infection of a nurse by a syphilitic child. Yet with all these mistakes, which it has taken nearly a century to correct, we owe John Hunter a great debt of gratitude for his unfailing faith in mercury as the specific remedy for syphilis. So long as varieties of venereal sores were undistinguished mercury was, of course, often given unnecessarily and with disastrous effects; but if it had not been for Hunter it seems likely that the heresy which the Bells and other Scotch surgeons promulgated, that syphilis did not require mercury for its cure, would have made much greater way than it did. Thanks to the labours of Ricord, Hutchinson, and Hill, the diagnosis and treatment of syphilis are now placed on a firm basis; and if it had not been for the "shrieking sisterhood" and the action of a few effeminate Members of Parliament we might now be rejoicing in the reduction of venereal disease in our army and navy by those most beneficent laws known as the "Contagious Diseases Acts," which were unhappily wiped out by a weak-kneed Government just when they were conferring the greatest benefit upon suffering humanity.

The papers which John Hunter himself contributed to the Transactions of a Society for the Improvement of Medical and Chirurgical Knowledge were only two in number. The first was read on Feb. 6th, 1784, and was "On the Inflammation of Internal Coats of Veins." The frequency of phlebotomy gave rise, as he says, "to a very frequent complaint—that is, an inflamed arm after bleeding"; and he proceeds to show that this arose from the wound not healing by first intention. Numerous post-mortem examinations enabled him to state correctly enough that, as the result of inflammation of the lining membrane of the vein, in some cases adhesion of the coats and obliteration of the canal took place, whilst in others suppuration ensued and abscesses had to be opened, or led to the death of the patient by what we now term pyæmia. It is remarkable that Hunter does not mention thrombosis and does not appear to have recognised the formation of clot in the vein as an early stage of phlebitis.

In the treatment of phlebitis Hunter urges the application of a compress to produce adhesion of the surfaces of the vein; and though this can be but of little service it is noteworthy that he should have anticipated the proposal of Mr. Henry Lee to pass a pin beneath the vein, so as to prevent pus getting into the circulation, by upwards of seventy years. Nothing is more remarkable in the present day than the almost absolute safety which attends the removal of portions of varicose veins, as recommended by the late John Marshall, provided strict attention be paid to asepsis.

Hunter's second paper was read on Aug. 18th, 1789, and was "On Introsusception"—as it was spelt in those days. He says: "When the introsusception is downwards it may be called progressive, and when it happens upwards, retrograde"; and attributes the slipping of one piece of intestine within another solely to some additional weight in the gut above. Again, Hunter says: "The outer fold is the only one which is active, the inverted portion being perfectly passive and squeezed down by the outer, which inverts more of itself." Although these views are not received in the present day, the figures of two cases of intussusception which Hunter gives most accurately represent the disorder and could not be improved upon. His treatment is curiously dominated by his views as to the action of the outer fold of the intussusception, for he says: "Medicine can never come in contact with the outer fold," and he advises, therefore, giving vomits, "with a view to invert the peristaltic motion of the containing gut, which will have a tendency to bring the intestines into their natural situation." It is remarkable that neither inflation of the bowel from below, which dates from Hippocrates, nor the proposal of Praxagoras to open the abdomen and thus reach the seat of trouble, which in modern times has proved so successful, receives any mention in this essay.

John Hunter seems to have been the originator of the practice of feeding artificially through a stomach-tube. He read before the Society for the Improvement of Medical and Chirurgical Knowledge on Sept. 21st, 1790, "A Case of Paralysis of the Muscles of Deglutition, cured by an artificial mode of conveying food and medicines into the stomach." The patient was a man, aged fifty years, a hypochondriac who lost the power of swallowing, and was brought to Hunter for relief. Hunter proposed that a hollow flexible tube should be passed down into the stomach, and mentioned his having an instrument of the kind made of spiral wire covered with gut for the purpose of injecting liquids into the stomachs of animals. The plan was adopted and the patient recovered. The instrument used was a fresh eel skin of rather small size, drawn over a probang, and at the end of the paper it is observed: "An eel skin seems very well adapted for this purpose, being smooth, pliable, and readily passed into the stomach; but as cases of this kind may occur when eels cannot be procured a portion of the gut of any small animal, as a cat or lamb, will make a good substitute."

This same volume of the society's "Transactions" contains a paper by Sir Everard Home "from materials furnished by Mr. Hunter." It is entitled, "Some Observations on the Loose Cartilages found in Joints," in which the view is maintained that the cartilages originate in blood-clots rather than in the loose fringes of the joint. Hunter advises the removal of such bodies by an incision above and to the inner side of the patella, and describes graphically the extreme difficulty of the proceeding, owing to the tendency of the cartilages to escape into the cavity of the joint.

I have thus endeavoured to show by his own writings that John Hunter was an able and experienced surgeon as well as an unrivalled anatomist. That he had been for some years before his death the leading surgeon in London cannot be doubted, for even Mr. Jesse Foot allows this. He says: "I think I may affirm that his consultations were more in fashion than any other surgeon's, and that his range of practice was more extensive—that we heard more of the name of John Hunter than of any other surgeon." Evidence of this kind is better than that which nowadays is too often looked upon as the test of professional success—the amount of legacy duty. Hunter died a poor man, not because he did not make a large professional income, but because he spent all he made upon his museum. When he died in 1793 we find his influential friends exerting themselves to procure a grant for his widow from the Government of the day; and eventually in 1793 Parliament voted £15,000 for Hunter's Museum and placed it under the care of the Corporation of Surgeons. The Royal College of Surgeons of England, the successor of that corporation, cannot be said to have failed in its duty towards Hunter's collection, and the splendid series of museums which the College has erected during the present century show the interest taken

Hosted by Google

by the Council of this College in the promotion and advancement of the art and science of surgery.

[Mr. Heath concluded, according to custom, with an eloquent reference to those Fellows of the College who had died since the last oration—namely, John Whitaker Hulke, William Savory, Arthur Durham, John Eric Erichsen, George Murray Humphry, and Spencer Wells. His peroration was as follows:—]

And now, Sir, having completed the roll of the illustrious departed, let me conclude by saying a few words on my own behalf. In July my period of office as a Councillor of this College expires, and this is, therefore, the last occasion on which I shall have the right to address my colleagues and the College at large from this place. Gentlemen, I cannot but view the future of this College with some anxiety. This great corporation is, I fear, on the high road to become something very unlike the Royal College of Surgeons of England which has existed now for nearly 100 years. Hitherto it has been regarded as the home of surgical science and its funds have been devoted to the advance of the art of surgery by providing unrivalled opportunities for study in its museum and library. This College will, in my opinion, lose professional prestige and fall in public estimation if its funds should ever be diverted from these legitimate purposes in order to support the interests of individual members of the profession, however worthy in themselves. It will be a melancholy day for British surgery if ever this Royal College should become a gigantic Protection Society to fight the puny battles of its Members who may happen to come into collision with each other or with the public. It is to the Council, and to the Fellows who elect the Council, that we must look for the maintenance of that high professional position which this College has hitherto occupied and for the furtherance of the art and science of surgery—*quæ prosunt omnibus artes.*

ABSTRACT OF

An Oration

ON

WILLIAM HUNTER (1718-1783),

ANATOMIST, PHYSICIAN, AND OBSTETRICIAN.

WITH NOTICES OF HIS FRIENDS,

CULLEN, FOTHERGILL, SMELLIE, BAILLIE, ETC.

Delivered on Feb. 10th, 1897, before the Hunterian Society

BY R. HINGSTON FOX, M.D., M.R.C.P. LOND.,

PHYSICIAN TO ST. LUKE'S MISSION DISPENSARY.

[AFTER the customary words of address to the President and Fellows Dr. Hingston Fox referred to the practice in vogue in the eighteenth century of leading medical men advertising their lectures in the ordinary newspapers of the day, and quoted an example of one inserted by William Hunter. The date of this, his first, was 1746. He then briefly referred to Hunter's family, his youthful days, and his friendship with Cullen. He spoke of Hunter's entry into London, where he made the acquaintance of Smellie, Dr. James Douglas, and Nicholls of St. George's Hospital. Dr. Fox continued: "It is as anatomist, physician, and obstetrician that I desire to bring Hunter before you this evening." The orator then gave a short account of the leaders in medical science at the time he spoke of—such as Richard Mead, Sir Hans Sloane, Cheselden, Pott; and, abroad, Boerhaave, Haller, Morgagni, and Linnæus. He continued:—]

William Hunter in 1747 became a member of the Corporation of Surgeons. In the next year he travelled on the Continent with young Douglas, going through Holland to Paris, and visiting some of the medical schools. In particular he went to see Albinus, one of the greatest of Boerhaave's pupils, who held the chair of anatomy at Leyden for the long term of fifty years. Here he saw some of the injected preparations for which that anatomist was famous, and was led to use this method of investigation in his own future work with signal success.

In 1748 his youngest brother John, ten years his junior, came up to London, fired, it would seem, by the same desire of a larger field for his energies. He wrote to offer his services to William as an assistant in his dissecting room. William replied with a kind invitation to visit London. John Hunter became at once his brother's pupil and assistant and was inducted by him into the anatomical studies in which he was to spend most of his life. He soon showed great skill in dissecting and injecting specimens and assisted his brother in many of his researches in anatomy and physiology, making discoveries more or less in conjunction with him. These, as we shall see, were afterwards a fruitful source of dispute between them. For several years after John came to London his elder brother sought to direct and help him in his studies, placing him under Cheselden and under Pott. He even tried to give him what he had himself enjoyed—a university training—but John's stay at Oxford was very brief and to little purpose, and he referred very ungraciously in after life to the efforts that had been made on his behalf. Indeed, it must be acknowledged that the younger brother gave during these early years little comfort or satisfaction to his friends. His manners were rough and coarse and his associates low. Indications of this occur in the letters which have been preserved. The dispositions and training of the two brothers were so different that it is hardly to be wondered at that they diverged as time went on. William, with his culture and polite instincts, had a trait of strictness and severity in his character, although he was kind at heart. Yet he refers often to his brother John in his lectures and in his medical commentaries in appreciative terms. And it was principally through William's powerful interest that John was elected to his most important appointment in the year 1768—that of surgeon to St. George's Hospital. John once sent him a patient with the following laconic note: "Dear Brother,—The bearer is very desirous of having your opinion. I do not know his case. He has no money and you don't want any, so that you are well met.—Ever yours, JOHN HUNTER."[1] John left his brother's laboratory in or before 1761, going abroad on account of his health as a surgeon in the army, and was succeeded by Hewson, a very able young anatomist with whom after some years William disagreed, and Cruikshank was engaged in his place in 1770. Hewson made important researches into the lymphatic system, discovering the existence of these vessels in birds and fishes, and demonstrating the human lymphatics with a fulness hitherto unattained. He died at the age of thirty-four years; his works have been published by the Sydenham Society. A curious letter is extant from Benjamin Franklin, who, during his stay in England, lodged at one time with William Hunter and Hewson, and "as a common friend had been obliged to listen to their mutual complaints." He writes to William Hunter in 1772 to give evidence as to the terms of agreement between them.[2]

In 1750 William Hunter received his degree of Doctor of Medicine from Glasgow University, gave up surgical practice, and left the hospitable roof of Mrs. Douglas to take a house in Jermyn-street, where he practised as a physician. By this time he had made various communications to the Royal Society; the first was as early as 1743, when he was but twenty-five years old, on "The Structure and Diseases of Articular Cartilages." At that time, and, indeed, throughout the eighteenth century, papers on medical subjects were laid before the Royal Society in large numbers. He was elected a Fellow 1767, in the same year as his brother. It may be added here that in 1768, on the foundation of the Royal Academy by Joshua Reynolds, Gainsborough, and others, Dr. Hunter was appointed its first Professor of Anatomy. A painting in the Royal College of Physicians of London, of which he became a Licentiate in 1756, represents Hunter lecturing to the members of the Academy. In his practice Hunter had come to turn his attention especially to midwifery, and he had been appointed man-midwife to the Middlesex Hospital in 1748 and surgeon-accoucheur to the British Lying-in Hospital next year. In this branch of medicine his reputation constantly grew, until in the year 1762, when he was forty-four years of age, he was called in to see the young Queen of George the Third. The story is told that the King asked him when he came out of the

Hosted by Google

chamber what ailed Her Majesty, and that he replied, "The Queen is *with bairn*." I have not found any written authority for this story. In any case, his attendance gave much satisfaction, and he was two years later named as Physician Extraordinary to the Queen, and from this date his practice amongst the upper classes rapidly increased. Hunter's polished manners and refinement, coupled with much shrewdness and a careful attention to his patients, made him a *persona grata* with persons of rank, whether by title or talent. The letters existing prove that he was on terms of easy acquaintanceship with many of the nobility, such as the Earls of Chatham and Rockingham, Lord North and Lord Bute. Horace Walpole writes to him in 1773 to promise him Lord Orford's "original"—an American Moose deer.[3]

Hunter's character is placed in a favourable and interesting light by some letters which passed between him and the Earl of Suffolk, whose lady he had attended at her death in childbed in 1767. Lord Suffolk had addressed to Dr. Hunter a letter full of the most affectionate gratitude for his attention and help: "My busyness is to beg of you, if *Reward* is an irksome word, to let me substitute *Regard* in its room." Dr. Hunter, after warmly thanking Lord Suffolk for his letter, continues: "I am now by your Lordship's kind sympathy as happy as I can be after taking such a share in so great a calamity. I feel an inclination to say a thousand things which I must suppress. I wish to talk upon a subject which you must forget. We will take it up in Heaven. At this moment I fancy that I have a Friend there who listens to my thoughts and bids me say to you in a little time we shall all be happy again; who bids me tell you to take care, for her sake, of yourself and of your child. Allow me to love your child all the days of my life; she will be exactly what you describe and what you wish. Allow me sometimes to see her, that I may indulge a pleasing melancholy and fancy that I am doing something very agreeable to Heaven. It may be preparatory to some exalted enjoyment there. Allow me likewise to offer your Lordship the best advice I can. As soon as possible do a force to nature and go into the bussy world again. Nothing but that, I think, can restore your peace of mind and make you what I am sure you wish to be, a Blessing to Mankind. May you yourself be blest, both for your own sake and for loving so tenderly one so worthy of all your affection."[4]

[Dr. Fox then gave an account of Hunter's museum and proceeded:—]

He sought, but sought in vain, to construct on the basis of this museum and his lecture classes a national school of anatomy. He was ready to erect the building and to endow it with the sum of £7000. But his application in 1765 to the Government of the day to grant a site was unheeded, and the golden opportunity which might have done much for British medicine was suffered to pass by. It was a bitter disappointment to Hunter, and although Lord Shelburne sought as an individual to undo the ill act of the Cabinet, and offered to head a subscription list with a promise of a thousand guineas, Hunter's pride would not stoop to accept it. He turned to rely upon his own unaided efforts. A plot of ground was purchased in Great Windmill-street, near the present Piccadilly-circus, and here in 1770 he built a spacious house, containing a large room for his museum, a lecture theatre, and dissecting-rooms, besides rooms for his own residence. Here he lived and taught for the remaining thirteen years of his life. The house was afterwards occupied by his nephew, Dr. Matthew Baillie, and it was there Joanna Baillie began to write her dramas; it still stands, a plain red brick structure, somewhat altered, the portico gone, and the building now incorporated in the Lyric Theatre.[5] Hunter was a keen and jealous controversialist, laid exaggerated stress upon his discoveries, and was too sensitive of his own fame as an original worker. He was conscious of this weakness—an inordinate love of controversy, and condoned it on the plea that the passive submission of dead bodies rendered anatomists impatient of contradiction.

[3] Ibid., 128.

[4] Ibid., pp. 102-104. Henry, twelfth Earl of Suffolk, was K.G. and Secretary of State for the Northern Department. The story of his deep attachment to his wife and sorrow for her early death, of his devotion to the child named after her, and of her death at eight years is a pathetic one. He married again later, but it was not like the first love. He died before the age of forty years. I have to thank the Countess of Suffolk for her courtesy in supplying information.

[5] The house of John Hunter on the east side of Leicester-square, containing his lecture theatre, dissecting-rooms, &c., is at the present time about to be absorbed by the Alhambra Music-hall, which adjoins it.

[Dr. Fox then mentioned the two great controversies of Hunter's life, that with the Monroes with regard to priority in the discovery of the tubuli testis, and the bitter dispute with his brother as to the double circulation in the placenta.]

An estrangement resulted between William and John and they scarcely met again. After Haller died Hunter was chosen, in 1782, to occupy his place as one of the eight Foreign Associates of the French Academy—perhaps the highest foreign honour a man of science can obtain. Haller's seat had been occupied before him by Morgagni, and before him by Ruysch. On this occasion the chymists, one of the eight classes into which the Academy was divided, wished to have Bergman, the Swedish chemist, elected, but the class of anatomists insisted that it was their right to appoint a foreign associate, and Hunter was chosen.[6] We do not find that Dr. Hunter took much part in the political events of his time, nor did John Hunter on his part. A letter to a friend, written in 1778, five years before his death, concludes: "I told you that I have taken my leave of Politics: and am sorry to say that as far as I am a judge this country deserves humiliation, or rather a scourge. God bless you.—WILLIAM HUNTER."[7] The times, indeed, looked dark and threatening. Great Britain was at war with the United States and with France, and Spain was just declaring war against us. The long contest in Hindostan was in its early and more doubtful stages. At home there was trouble and discontent. And who that could have foreseen the prolonged struggles that were to come during nearly forty years would not have lost heart for the future of our country? Yet through all the staying power of the Anglo-Saxon race proved equal to the strain. William Pitt became Prime Minister in the year that Hunter died.

Ten years before his death, despite his frugal manner of living, Dr. Hunter began to suffer from "wandering gout," affecting, we are told, sometimes the limbs and sometimes the stomach. His bodily powers, strained by incessant exertions which he would not relax, gradually waned, but the spirit was active and undaunted to the end. On March 20th, 1783, he rose from his sick-bed, against the remonstrances of his friends, to deliver the introductory lecture of his course—an occasion when there was a large and more general audience. Towards the end of the lecture he fainted and had to be carried from the theatre. He never rose again, but died quietly, a few days later, on March 30th. John Hunter came to see him again and again in his illness and gave him needed surgical attention (catheterism). The brothers were reconciled at last, for dividing lines belong to life. As it has been finely said: "It is death alone which integrates." He died in peace. "If I had strength enough left to hold a pen," he said to Dr. Charles Combe, his executor, "I would write how pleasant and easy a thing it is to die." William Hunter was only sixty-five years of age, the same age attained by his brother John ten years later. Both died in the fulness of their work, closing a life of strenuous labour. So died their nephew, Matthew Baillie; so died many other masters in our art, from the days of Sydenham and of Radcliffe down to those of our own Wilson Fox and Andrew Clark. He was buried in the rector's vault of St. James's, Piccadilly, where his monument stands between those of Sydenham and Richard Bright.

[Dr. Fox then went on to speak of Hunter in the triple *rôle* of anatomist, physician, and obstetrician. With regard to the first of these "persons" he quoted from letters showing that Hunter was a close student of nature. He mentioned the discovery of the tubuli testis, the lacrymal ducts, the origin and use of the lacteals and lymphatics, the mode of formation of congenital herniæ, the anatomy of aneurysms, the placental circulation, the nature of the fœtal coverings, especially the decidua, and, above all, the anatomy of the gravid uterus. The Great Windmill-street School was referred to and stress laid upon the fact that William Hunter shone, not only by his own glory, but by the light reflected from his celebrated brother and pupil, John. Dr. Fox continued:—]

In speaking of William Hunter as a physician I use the latter word in no restricted sense. Perhaps the departments of medicine were not then so strongly marked out from one another; at any rate, Hunter took no narrow view of his profession. He began his medical life as an anatomist, practising surgery the while; then he took a physician's

[6] MS. letter to W. Hunter, announcing this honour, in possession of Miss Hunter-Baillie.

[7] Letter in possession of Miss Hunter-Baillie.

Hosted by Google

degree and finally devoted himself chiefly to the practise of midwifery. Nothing, indeed, that came within the scope of medicine in its widest sense was foreign to his mind. He made many contributions to the six volumes of "Medical Observations and Inquiries," published between 1757 and 1812 by that "Society of Physicians" which was the precursor of the Medical Society of London and is often confounded with it. Hunter succeeded his friend Fothergill as president of this society. Several of the papers relate to aneurysm and to his discovery of varicose aneurysm, others to the advisability of operating in empyema when there is no more than a reasonable probability of finding pus, to necrosis of the tibia and the nature of callus, and to rupture of the capsular ligament in dislocations at the shoulder. There is one very careful and elaborate record of a case of traumatic emphysema, in which the cellular tissue of the whole of the body was inflated with air.[8] The patient was *in extremis*, but Hunter, by suitable incisions, pressing the air out, and stopping the injured thorax, succeeded in effecting a cure. He goes on to expound the nature and functions of the cellular tissue and the use of punctures in anasarca; these should be very small, rather than large, as he had learned by trial of both these methods, one on each leg of the same patient. He had dissected black cattle, dead from an epidemic disorder attended with emphysema. Other papers deal with the structure of the symphysis pubis and the insensibility of tendon.

[After referring to two papers of Hunter upon congenital heart disease, wherein Hunter certainly foreshadowed the doctrine of evolution, the case quoted by Watson of the boy with anorexia, and a medico-legal paper upon child murder, Dr. Fox passed to consider Hunter's friends, Cullen and Fothergill, and also his nephew Baillie. Of Hunter as an obstetrician he said:—]

I pass on to speak of William Hunter as an obstetrician. The art of midwifery was passing in the middle of the eighteenth century through a severe struggle. When Smellie settled in London in 1739 the bulk of the practice was in the hands of midwives. Mrs. Nihell of the Haymarket, who afterwards published a treatise on the subject, had a large practice, and was a doughty and uncompromising champion of the exclusive right of her own sex to practise the art. Between her and Smellie, who lived hard by in Pall Mall, there was unceasing war. There were, indeed, men physicians devoted to this art, but when they were called in it was often only to advise the midwife, the patient not permitting herself to be touched. When William Hunter attended the young Queen of George III. he merely waited in an ante-room in case the midwife needed his assistance. The principal men-midwives when Smellie and Hunter began to work were Dr. Maubray and Sir R. Manningham. Of the former it need only be mentioned that he stated a decided preference for a seven months' term over a nine months' gestation on account of the influence of the moon and the mystical value of the number seven. Manningham was of a higher order and long enjoyed the chief reputation in London, where he founded the first maternity institution. He detected the imposture of Mary Tofts, the "rabbit-breeder." Yet so far was the art in its infancy that in his Compendium, published in the year that Smellie commenced practice, no mention is made of any sort of instruments. Instruments, however, were in use, but mainly of a destructive kind, and it was Smellie's earnest desire to find better methods, so that in difficult cases the child's life should not be sacrificed, that brought him to London.

[Here Dr. Fox gave a short account of Smellie and continued:—]

William Hunter was for many years the acknowledged leader in obstetric practice in London. In dealing with his claims to distinction in this department I am glad to be able to quote one who wrote with authority, the late Dr. Matthews Duncan. In his "Researches in Obstetrics" Dr. Duncan quotes Dr. Hunter many times; for example, on the inclination of the axis of the uterus, the plasticity of the uterus adapting itself to the shape of the fœtus, the condition of the cervix during pregnancy, the cause of the fœtal head being commonly downward, the especial development of the cephalic end of the fœtus, the posture of the child during the last months of gestation, the early implantation of the placenta over the cervix, the separation of the fœtal from the maternal portion of the placenta in a four months' conception, and the operation of symphysiotomy.

Smellie acknowledges the help derived from Hunter's "reforming the wrong practice of delivering the placenta"—i.e., leaving it more to natural efforts. And Hunter's lectures, preserved to us in the notes of students, bear witness to his thorough grasp of the practical issues of his art. He describes, for instance, clearly and simply, the occurrence of fever, convulsions, white leg, hemiplegia, &c., in the puerperal state, and his treatment, if rather conservative and inactive, is at any rate free alike from active hurtfulness and from a pretence of specifics.[9] Hunter described the retroversion of the gravid uterus apparently for the first time, and proposed the name by which the displacement is now known. His papers on this subject are very clear and interesting.[10]

A few words remain to be said on William Hunter's personal character. His many-sided tastes have been referred to. It is wonderful, perhaps, that they did not hinder him from attaining high distinction in his own profession. But he had no wife or child, and his museum was the recreation of his leisure hours. A man of untiring industry, an early riser, exact and orderly in his habits, thoughts, and speech, he combined the learning of a scholar with the refined manners of a gentleman. He was kind and he was just; and if he was so conscious of his own abilities and so sensitive to praise or blame that he sometimes appeared jealous, sometimes even bitterly combative in his attitude to others, such feelings did not long disturb his peace of mind. "I am, I believe, one of the happiest of all men," he writes to Cullen in 1768, "though my hurry is somewhat greater than I could wish."[11]

I have thus sought to set William Hunter before you as a great anatomist and a sound and successful practitioner of medicine and of midwifery.

"Verax: capax, perspicax: sagax, efficax: tenax."

A teacher of renown and wide influence, he contributed greatly, with his brother, John Hunter, to establish medical science and art upon the only sure foundation, that of anatomy. May we not rightly speak of "the era of the Hunters" and associate the two brothers together in the great work they did for natural science?

[Dr. Fox concluded by a *résumé* of the scientific work of the time, and ended his address by thanking those who had given him assistance by placing at his disposal the various manuscripts, books, &c., which he had used in preparing it.]

BIRKENHEAD MEDICAL SOCIETY.—A meeting was held on Feb. 12th, the President (Dr. R. Sydney Marsden) in the chair. — Mr. S. Wilkinson opened a discussion on Hypnotism in an able paper, giving some interesting details of his own experience, and in the subsequent discussion the following members took part — Dr. Pinkerton, Dr. Brien, Mr. Harrington, Dr. McSwiney, and the President. — Mr. Wilkinson replied.

ROYAL LUNATIC ASYLUM, ABERDEEN. — The report by Dr. William Reid, physician and superintendent of this asylum for 1896, states that on Jan. 1st last year there were 741 patients on the register: admitted during the year, 207; discharged, 157 (recovered, 95; relieved, 33; not improved, 29); died, 55—leaving at Dec. 31st, 736, including 5 absent on probation. A great many of the cases admitted were in indifferent physical condition, and several of them exhibited symptoms of incipient phthisis. The percentage (45·9) of recoveries to admissions is higher than for many years. Dr. Reid calls attention to the large number for this asylum of deaths from general paralysis and from phthisis. The new hospital (opened on Aug. 3rd) promises fully to realise expectations. The ventilating and heating system have proved satisfactory, and the electric lighting is for asylum requirements a decided advance. The income amounted to £23,342 and the expenditure to £23,435. In all 948 cases were under treatment last year, and the directors are to hold in the spring of this year a conference with Her Majesty's Commissioner in Lunacy as to the re-construction of the main asylum.

ABSTRACT OF

The Hunterian Lectures

ON

THE PATHOLOGY AND SURGERY OF INTUSSUSCEPTION.

Delivered at the Royal College of Surgeons of England,

BY D'ARCY POWER, M.A., M.B. OXON., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR OF SURGERY AND PATHOLOGY; SURGEON TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

LECTURE III.[1]

Delivered on Feb. 12th.

THE TREATMENT OF INTUSSUSCEPTION.

TURNING from the theoretical to the more severely practical aspects of intussusception, there can be no doubt that all cases of the affection have to be treated upon the assumption that they are either reducible or irreducible. I do not propose to occupy your time with a history of the treatment of intussusception. Those who are interested in such matters will find that Professor Ashurst,[2] Dr. Leichtenstern,[3] and Mr. Jonathan Hutchinson,[4] have published admirable summaries of it from different points of view. It is still necessary, however, to teach the majority of mothers that early advice and abstention from domestic remedies are required in all cases of painful constipation occurring suddenly in young children, just as it is only lately that men, as well as women, have come to understand that the immediate treatment of strangulated hernia means recovery, whilst to delay is death. It is evident, indeed, that we are tracing in this century the exact course which our predecessors in the last century had to follow in regard to the treatment of hernia. Obstinate and ignorant people exist now as they did then, who would treat an intussusception with the same masterly inactivity as their ancestors treated hernia, and upon the identical plea that such a line of treatment yields a few spontaneous recoveries.

a. Reducible intussusception.—Clinical and pathological evidence show that an invaginated portion of the intestine has a constant tendency to reduce itself until its muscular coat becomes paralysed or adhesions are formed at its neck. This tendency to reduction is probably counteracted during the earlier stages of an intussusception by the tonic contraction of the ensheathing bowel, for if this be reduced or abolished by mechanical or other means the intussusception can be easily reduced until hardly any invagination remains. Inflation or injection of the large intestine is, upon the whole, the safest and the most satisfactory treatment for all cases of uncomplicated intussusception, provided that the patient has been seen early enough, that the distending force be applied gradually, and that it be not too great.

b. Treatment by irrigation.—Injection is preferable to inflation because the force employed can be graduated with much greater accuracy, whilst the apparatus is always at hand. But irrigation is not of the least service in the enteric form of intussusception, where one part of the small intestine is invaginated into another; for many observers[5] have shown by experiments on living and on dead bodies that fluid can only be made to pass through the ileo-cæcal valve when over-distension of the colon has caused a mechanical separation of its two segments. Such an over-distension, however, is in the highest degree dangerous, because it is usually accompanied by a cracking of the serous coat of the large intestine, which is soon followed by rupture of the muscular and mucous layers if the force be continued. The method of irrigation under hydrostatic pressure is the most satisfactory way of distending the colon in cases of colo-colic and ileo-cæcal intussusception. The fluid is allowed to pass into the large intestine by its own weight, so that the force can be accurately estimated by observing the height to which the reservoir is raised above the recumbent body of the patient. The valuable experiments of Mr. Mortimer[6] in London and of Mr. Mole[7] in Bristol have greatly increased our scientific knowledge of the effects of irrigation in the treatment of intussusception. They have shown that the results depend partly upon the obstruction to be overcome within the intestine and partly upon the external support. The greater the pressure within the abdomen the more is the distending force neutralised, for the intestinal wall is then compressed between two opposing forces. There is apt to be cracking of the serous coat of the large intestine when the resultant pressure of the fluid distending the colon is about two and a half pounds per square inch—that is to say, when the irrigator is raised five feet above the body of the patient, and this accident usually happens when the irrigator is raised to eight feet, though the bowel may be completely ruptured when the reservoir is only raised to a height of six feet. Rupture of the large intestine is most likely to occur in the transverse colon at or near the splenic flexure, whilst in the small intestine it takes place in the unprotected portion of the bowel which is situated between the two layers of the mesentery. It is impossible for the surgeon to estimate the capacity of the colon in any individual case of intussusception, nor can he judge the amount of pressure that may be applied with safety to the inflamed and softened intestinal wall at the neck of the tumour. A pint of fluid was sufficient to rupture the bowel in a child,[8] aged three months, though the injection was made by one of the most careful and experienced surgeons in the profession. Dr. Muir, at my instigation, has measured the capacity of the colon in the bodies of several children, and the measurements show how widely different is the capacity of the colon in different children of almost the same age. Thus in a male child aged five months ten ounces of water were sufficient to distend the colon, whilst in a girl aged seven months thirty ounces could easily be passed into the large intestine. Forty-eight hours is the limit of time within which irrigation is likely to be successful in an ordinary case of ileo-cæcal intussusception with tolerably acute symptoms, and such pressure is alone justifiable in a child aged two years as can be obtained by raising a reservoir of water containing a quart of salt solution at 100° F. two and a half feet above the anæsthetised patient. I do not think that inversion of the patient renders irrigation more successful, but I am satisfied that long-continued distension under a low pressure is of more avail than rapid dilatation under a high pressure. The surgeon should keep one hand flat upon the abdomen whilst irrigation is being performed, and he must carefully avoid great variations of pressure. A sudden and uniform enlargement of the whole abdomen during the irrigation raises a strong suspicion that the bowel has been ruptured. A laparotomy must be done at once when this accident happens, and the seat of rupture should be looked for either on the left side of the abdomen or at the neck of the intussusception. The length of the intussusception is no bar to its reduction by irrigation, for many cases are recorded in which an intussusception has been reduced even when the ileo-cæcal valve has protruded beyond the anus.[9] A chronic case with a great deal of glairy discharge, the onset of which has been heralded by similar attacks of less intensity, may be treated by irrigation a very much longer time than is allowable in ordinary cases; indeed, some cases[10] of this nature have been cured when the symptoms have lasted from four to six months. The duration of the symptoms is perhaps always of less importance in an intussusception than their intensity. The longer the time the symptoms have lasted, however, the more likely it is that adhesions will have been formed. Slight adhesions are not an insurmountable barrier to reduction by irrigation, though they militate greatly against its success as Professor Senn's[11] investigations showed.

A great disadvantage attends the use of irrigation for the cure of intussusception apart from the danger of rupture. This disadvantage is the liability to recurrence after

reduction. Dr. F. H. Elliott[12] has published the details of a case of recovery from intussusception in a child, aged eight weeks, in whom recurrence took place twenty-four hours after the first reduction, five days after the second reduction, and thirteen days after the third reduction. Dr. Chaffey[13] had a less satisfactory experience, for an intussusception recurred on five separate occasions until the patient—a boy aged three years—died from exhaustion. When recurrence is a very marked feature in a case it is better to open the abdomen at once rather than to trust to repeated irrigation of the bowel, for it appears[14] that re-invagination can positively be prevented by shortening the mesentery at the point of invagination by folding it upon itself in a direction parallel to the bowel and maintaining it in this position by a few catgut sutures. No absolute rule can be laid down, however, for a child is now under my care who has apparently been cured of an intussusception, though irrigation had to be done on five separate occasions before the tendency to recurrence was overcome. A second objection to this method of treatment lies in the fact that the operator cannot see what he is doing. The reduction is, therefore, incomplete in some cases, for the last part of an intussusception is the most difficult to unfold. Cases are well known in which such an incomplete reduction has been found at the necropsy.[15] The ileo-cæcal valve, too, is sometimes a cause of trouble after the reduction of an intussusception, theoretically because a hæmorrhage into its substance may make its segments gape, or may so stiffen them as to predispose to a fresh invagination of the ileum, practically because it may be mistaken in its inflamed state for the tumour of an intussusception.[16] The after-treatment of an intussusception which has been cured by irrigation must consist in keeping the patient absolutely at rest, in the administration of opiates, and in feeling the abdomen gently from time to time to ascertain that the tumour has not recurred.

c. Treatment by Abdominal Section.—When irrigation has failed to relieve an intussusception the method must not be continued for too long a time, because the patient may become collapsed, even though no injury be done to the bowel. Abdominal section must then be performed at once, and this forms the second great method of treating intussusception. The failure of irrigation, because it leads to the necessity for laparotomy, increases the surgical interest of the case tenfold, but unfortunately it adds greatly to its gravity; for whilst the mortality of intussusception in infants treated without operation is calculated in the latest series of tables at 59 per cent., the mortality amongst the cases in which the abdomen had been opened is 67 2 per cent. Dr. Wiggin,[17] who appears to have compiled these statistics with great care, explains that this high rate of mortality is due to the inclusion in his tables of all cases in which laparotomy has been performed. The risk of abdominal section is reduced to 22 2 per cent., if only those cases be reckoned which have been operated upon within forty-eight hours of the onset of the symptoms and if we only take into account the cases which have been submitted to operation since the year 1889, when the more perfect technique of abdominal surgery has become generally known. Such an estimate, however, is based necessarily upon published cases, and is probably inaccurate, for no record has been kept of many unsuccessful operations.

Shock is the great and immediate cause of danger in every case of abdominal section performed upon a young child for the relief of an intussusception. Chilling of the body, bleeding, and powerful nerve stimuli ascending to the spinal cord from the splanchnic region, are the causes of shock, and they should be reduced to a minimum. Chilling of the body is easily prevented by placing the patient upon a hot-water bed and by swathing the arms and legs in cotton-wool, whilst the chest is covered with a roughly-made jacket of Gamgee tissue. The subcutaneous injection of one-fiftieth of a grain of strychnine, with enemata of brandy and hot water, will cause a temporary rally lasting long enough for a simple abdominal section to replace a piece of invaginated intestine in a child, though in a long operation these measures must be repeated more than once. The anæsthetic should be given sparingly. The incision should be made in the middle line, and at first it should only be long enough to admit two fingers and a thumb into the peritoneal cavity, for in the simplest cases it is unnecessary to drag the intestine to the wound. Indeed, it is better not to do so, because such a proceeding stretches the mesentery, and so stimulates the nerves that the splanchnic vessels are first contracted and afterwards dilated, leading to as great a lowering of blood pressure as would be caused by a very serious hæmorrhage. The less the intestine is handled, therefore, the better it will be for the patient, but it is much better to enlarge the incision and to bring the tumour into view if there is any difficulty in reducing the intussusception rather than to run any risk of tearing the serous coat by manipulating the intestine in too cramped a space. Rapidity combined with caution is the golden rule in all cases of abdominal surgery, and if it be followed in these cases the operation of laparotomy, even in a young child, is no more dangerous than is the ordinary operation for the relief of a strangulated hernia in an adult. The mortality rate of 22·2 per cent. applies more especially to this class of cases, and though it is still far too high we may hope that, as time proceeds and the cases are seen earlier, it will be still further and very greatly lowered. Washing out the peritoneal cavity is wholly unnecessary in the simpler cases; it lengthens the operation and increases the shock without yielding any adequate result.

An intussusception sometimes recurs after it has been reduced, but recurrence is less usual after an abdominal section has been done than when reduction has been brought about by irrigation. In a few cases[18] the intestine has remained so œdematous that the tumour has been felt even after the wound has been closed, leading the operator to suppose that invagination had recurred. Such a condition may be distinguished from true recurrence by the fact that the swelling rapidly disappeared and with it the symptoms of obstruction. There is another condition equally uncommon in which after an abdominal section has been done and the intussusception has been reduced the patient passes one or two healthy motions and seems to be on the highway to recovery, but within a few hours or days he again becomes constipated, his abdomen becomes distended with flatus, and he dies. A case of this kind recently came[19] under my care in the person of a boy aged eight months who had suffered for thirteen and a half hours from symptoms of intussusception. Irrigation failed to reduce the intussusception, so I opened the abdomen and easily replaced the bowel without doing it any injury. The child afterwards passed two motions—one blood-stained, the other natural—and took his food well, digesting it. Forty-five hours after the operation he began to vomit, the intestines became distended, and he died with all the symptoms of intestinal obstruction. The examination of the body in the post-mortem room showed that the intestines were distended with flatus to within a foot of the ileo-cæcal valve. The distension stopped suddenly, although there was no visible cause for its arrest either outside or within the intestine or abdomen. The colon, like the lower part of the ileum, was collapsed. There was no intussusception and no peritonitis. Similar cases are recorded by Mr. Pick[20] and by Müller.[21] The bowel in these cases is paralysed at the seat of invagination, for it is sufficiently injured to destroy its functional activity, but not badly enough to destroy its vitality. If a similar case should unfortunately happen again in my practice, I shall inject hypodermically a grain or two of barium chloride in solution. The drug is a powerful stimulant of peristalsis, but its action is less severe than eserin. When an intussusception has been successfully reduced by laparotomy, the surgeon should satisfy himself before he closes the abdomen that he has overcome the only cause of obstruction and that the case he is treating is really as simple as it appears to be, for an intussusception may be complicated by a variety of troublesome and dangerous conditions. Dr. Handfield-Jones and Mr. Page[22] published the details of such a complicated case in which there were two intussusceptions of the colon and one of the ordinary ileo-colic

Hosted by Google

type in a boy aged five years, and I have already mentioned the less uncommon cases of double intussusceptions.

d. Irreducible intussusception.—Intussusceptions become irreducible under many different conditions. In the first place the intestine may be healthy, but it is kept invaginated by more or less extensive adhesions; by peculiarities of structure, such as twists in its axis or the forcing of one piece of intestine upon another; by great swelling of the intussusception, or by the presence of large tumours in the intussuscepted bowel. Secondly, an intussusception may become irreducible because the bowel is so gangrenous or ulcerated that the surgeon does not dare to exercise traction upon the tumour, nor does he dare to leave the injured intestine within the peritoneal cavity. It has already been pointed out that slight and newly-formed adhesions do not necessarily render an intussusception irreducible, even by such a simple method of treatment as irrigation, though their presence is of unfavourable augury, because increased force is necessary to effect reduction. The adhesions formed in an ordinary case of intussusception which has been allowed to run its course unchecked may be very extensive and very dense. Clinical observations show how widely different is the tendency to the formation of adhesions in different persons. Mr. Marsh[23] performed abdominal section on a child about fifteen hours after the onset of symptoms, only to find that the intussusceptum had become so universally adherent to its sheath that it was impossible to effect a reduction. A similar experience befell Mr. Makins[24] in the case of a child aged four years, who had suffered from symptoms of intussusception for forty-eight hours. On the other hand, the formation of adhesions is sometimes delayed for an indefinite length of time, as in the cases seen by Dr. Lettsom,[25] in which the symptoms of intussusception were of three months' duration, and by Dr. Leichtenstern,[26] where they had lasted eleven months, and yet the post-mortem examination showed that hardly any adhesions were present.

Gangrenous and ulcerating intussusceptions form the second great group of irreducible intussusceptions of the bowel. I have already occupied some part of your time with a consideration of gangrenous intussusception, so that I shall not deal further with its pathology or causation, except to say that it is only produced with the greatest difficulty in experimental invaginations upon animals. The treatment of an irreducible intussusception is fraught with danger, whether it be irreducible from mechanical obstacles on account of extensive adhesions or because of gangrene. The prognosis in these cases was formerly considered desperate, but the advance of abdominal surgery has led to a recognition of the extraordinary readiness with which wounds of the intestine repair when their edges are kept in proper apposition, and we now have good hope that our efforts will be crowned with success even in the most unsatisfactory conditions.

e. Doubtful cases.—When the surgeon has opened the abdomen and finds that the intussusception is greatly congested and has lost its gloss he must not too hastily assume that it is dead. A piece of intestine which is only congested will bleed if it be pricked, even though it has lost its lustre, and if it be gently stroked until its vessels are emptied the the blood will be seen to pass along the vessels again as soon as the pressure is taken off them. A piece of intestine in such a condition must be handled very tenderly. It is unnecessary to remove it, and the patient is often so collapsed as to render any prolonged operation impossible, even if enterectomy were advisable. The wisest thing to do in such cases is to wrap a layer or two of gauze round the injured intestine as soon as the invagination has been released. One end of the gauze is left hanging out of the abdominal wound, the intestine is laid inside the peritoneal cavity and the incision is lightly closed with temporary silk sutures. If the bowel ruptures the intestinal contents may then find their way out of the abdominal cavity, whilst if it recovers the gauze can be removed and the wound will close by granulations.

f. Simple irreducible cases.—In chronic cases, when the end of the intussusceptum is gangrenous; when the intussusception is short and when it is irreducible from adhesions, from the presence of a polypoid tumour, or from a bulbous enlargement of the end of the intussusceptum, the method recommended by Barker,[27] Jessett,[28] and Greig Smith[29] may give excellent results. The broad principle underlying each modification of the operation is to ensure the union of the intussuscipiens with the intussusceptum by inserting a continuous suture at the neck of the tumour, then to slit open the intussuscipiens, remove so much of the intussusceptum as lies dead or free, stop the bleeding, and sew up the wound in the sheath. It is sometimes impossible to remove the intussusceptum after it has been divided, and in such a case Leszczynski[30] left the piece of bowel in the large intestine to be dealt with by nature, and the patient recovered. These methods are useless when the intussusceptum is attached to the intussuscipiens by firm adhesions for any great distance, as in these cases the two cylinders of intestine may form a continuous tube. Mr. Sydney Jones,[31] recorded such a case occurring in a child, aged nine months, in whom an intussusception proved fatal after the symptoms had lasted nine weeks. The apposed serous surfaces were adherent along their whole length by firm fibrous tissue. An artificial anus would alone be serviceable in the treatment of such a case, or if the adhesions did not extend very low in the rectum Halsted's operation of lateral anastomosis[32] might be employed.

g. Enterectomy.—Partial operations are useless when the neck of the sac is ulcerated, when the sheath of the intussusception is gangrenous, or when the invagination is associated with malignant disease of the intestine, and it is exactly in these cases that the greatest and most satisfactory advance has recently been made in the surgical treatment of intussusception. The old operation of making an artificial anus for the relief of the worst cases of irreducible intussusception had long been condemned by the more thoughtful surgeons, and Mr. Howse[33] performed a formal enterectomy for the relief of a ruptured intussusception in a child aged five months in September, 1876. But it was not until 1885 that Professor Braun[34] in Germany and in 1887 that Mr. Lawford Knaggs[35] in England called attention to the feasibility of section and subsequent suture of the intestine in these cases, pointing out the great advantage to be gained by the operation over the older methods. Resection was at first associated with simple end-to-end suture of the divided intestine, which is theoretically the most perfect but practically the most difficult method of obtaining union. The results of simple end-to-end suture proved most unsatisfactory, and this method has now been abandoned for more complex operations, which have resolved themselves into the union with, and union without, the aid of mechanical appliances, the methods of Senn and of Maunsell respectively. Personally, I have no hesitation whatever in giving in my adherence to the non-mechanical party, for it seems to me that its methods are more simple, whilst its results are at least as good as those obtained by the mechanical school. Maunsell's method is particularly suited for the ileo-cæcal form of intussusception which is the more common, for the two pieces of intestine vary greatly in their calibre, so that the invagination is easy. For the present, however, Murphy's button seems to have the advantage, though I think that it is but a temporary one, for in all the cases where it has been used successfully the intussusception has been of the enteric form, where the serous surfaces are smooth and can be brought into sufficiently close approximation to ensure union by first intention. It must necessarily prove less useful in intussusceptions involving the large intestine because the appendices epiploicæ render it impossible to bring the two surfaces into regular and uniform apposition.

My own experiments carried on without a knowledge of the very valuable and more extensive work done along the same lines by Mr. Ballance and Mr. Edmunds,[36] have satisfied me that in animals Maunsell's method yields the most satisfactory results. It can be performed at a moment's notice and the entire operation, from the

first incision to the last suture in the abdominal wall, can be completed easily in thirty minutes. The outlook for cases of irreducible intussusception treated by enterectomy is distinctly favourable, whatever method be adopted. When Braun[37] published his statistics in 1885 he could only find a single case where recovery had followed enterectomy for the relief of intussusception. Rydygier, in his addendum to Braun's list, published ten years later, has been able to collect the records[38] of 25 cases published between the years 1885 and 1895 in which recovery has taken place after the intestine has been resected or an anastomosis has been made between two pieces of bowel for the cure of intussusception. I find that four more recoveries are to be added to this list. Two of these occurred in America,[39] where the operation was done for the relief of chronic intussusception in women and two were done in England for acute gangrenous intussusception in children. One of these cases is recorded by Mr. Mitchell Banks,[40] who tells me that the boy is still alive and well. The other case came under the care of my colleague, Mr. Pickering Pick, and, though it is still unpublished,[41] he has very kindly given me leave to say that it was that of a girl aged eight and three-quarter years, who had complained of pain after she had jumped off a form at school. The abdomen was opened on the seventh day after the onset of symptoms and a stinking intussusception was found two inches above the ileo-cæcal valve. It was cut away, and the two ends of the ileum were brought together with a Murphy's button, which was passed on the ninth day after the operation.

For the sake of completeness I will sum up the conclusions at which I have arrived in this lecture. Intussusception is a condition which brooks no delay in its treatment, for something must always be done at once except, perhaps, in those slight cases which are indistinguishable from severe colic. In all doubtful cases purgatives should be completely withheld. I found in my experiments that cats and rabbits bore a simple invagination with remarkable freedom from symptoms, and that after a varying period of time the invaginated bowel could be excised and the animal would recover. All the animals, however, to whom purgatives were administered after the intestines had been invaginated died when enterectomy was performed. Clinical evidence teaches the same lesson, for all the records of cases show that the symptoms have been seriously increased when the patient has been purged. The routine treatment of intussusception is to chloroform the patient and steadily to fill his large intestine with hot salt solution under a hydrostatic pressure of not more than 3 ft. in a child, the fluid being allowed to remain in the intestine at least ten minutes. The earlier this method is adopted after the appearance of the symptoms the better are the results obtained, but it should not be adopted in enteric intussusception, in cases where the symptoms are very acute, or in those where the absence of signs or symptoms, with a subnormal temperature, leads the surgeon to suspect that the intestine is becoming gangrenous. In these cases, and when the intussusception is not reduced after irrigation has twice been tried, and when after reduction the intussusception has twice recurred, the abdomen must be opened. The surgeon must then be prepared to deal effectually with the conditions he may find by such operative means as he can carry out with the least amount of shock and in the shortest space of time that is compatible with the safety of the patient. This will be ensured if he uses the method with which he is most familiar. But he should bear in mind that hardly a case can arise in which he is justified in closing the abdominal wound without at least an attempt to complete the operation by reducing or removing the intussusception. Such half measures as the formation of an artificial anus are hardly ever justifiable, and the results obtained by them are usually most disastrous.

GUILDHALL BANQUET TO POOR CHILDREN.—After paying all expenses, including the cost of 1000 hampers sent to poor crippled children, Mr. Alderman Treloar has given £34 6*s.* 1*d.*, the surplus of his fund, to Mr. J. Kirk, the secretary of the Ragged School Union.

SOME SMALL-POX STATISTICS.

BY SIDNEY COUPLAND, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL.

[WITH A COLOURED CHART.]

THE following figures[1] are derived from personal inquiry into the incidence of small-pox on households in three recent outbreaks—namely, (1) in the Dewsbury Union, 1891-92; (2) at Leicester, 1893-94; and (3) at Gloucester, 1895-96. They comprise information of:—Dewsbury: 544 households, numbering 3000 persons. Leicester: 193 households, numbering 1234 persons. Gloucester: 899 households, numbering 4861 persons. The small-pox attack-rates were:—Dewsbury: 3000 exposed, 887 attacked; rate 29·5 per cent. Leicester: 1234 exposed, 320 attacked; rate 25·9 per cent. Gloucester: 4861 exposed, 1717 attacked; rate 35·8 per cent. The small-pox mortality was:—Dewsbury (3000 persons): 83 deaths; mortality, 2·7 per cent. Leicester (1234 persons): 17 deaths; mortality, 1·3 per cent. Gloucester (4861 persons): 370 deaths; mortality, 7·6 per cent. The small-pox case-fatality was:—Dewsbury: 887 attacked; 83 deaths; fatality, 9·3 per cent. Leicester: 320 attacked; 17 deaths; fatality, 5·3 per cent. Gloucester: 1717 attacked; 370 deaths; fatality, 21·6 per cent.

At different age-periods these returns show (Table I.):—

TABLE I

—	Exposed.	Attacked.	Died.	Attack-rate.	Mortality.	Case-fatality.
Under 1 year.				Per cent.	Per cent.	Per cent.
Dewsbury	75	25	16	33·3	21·3	64·0

10 to 30 years.						
Dewsbury	1349	482	24	35·2	1·7	5·0
Leicester...	531	151	3	22·6	0·5	2·0
Gloucester	1751	594	48	33·9	2·7	8·0
30 years and over.						
Dewsbury	901	202	11	22·4	1·2	5·4
Leicester...	330	67	2	20·3	0·6	3·0
Gloucester	1507	482	73	31·9	4·8	15·1

Note.—In Dewsbury the age was not ascertained in 21 of the exposed, none of whom were attacked. In Leicester the age was not ascertained in 9 of the exposed, none of whom were attacked.

Proportion of vaccinated and unvaccinated.—For the sake of simplicity the whole series has been divided into two categories only, the "vaccinated" and the "unvaccinated"; but in detailed analysis it is necessary for greater accuracy to further sub-divide these categories. Thus the "vaccinated" group here includes those instances (few comparatively) where no certain evidence could be obtained as to the fact of vaccination and those in which vaccination had been alleged, but of which no ocular evidence could be obtained; again, amongst the "unvaccinated" are here included all those who at the time of the invasion of the house by small-pox underwent primary vaccination—a not inconsiderable number in Dewsbury and Gloucester. If these were separated the effect on the statistics would be a lowering of the proportion of the unvaccinated, with a raising of the attack- and mortality-rates among the latter. For the attack-rate and mortality of those who were "undergoing" vaccination were, the former especially, much below the figure obtained by their inclusion with the strictly unvaccinated. (See reports on these outbreaks in the appendices to the final report of the Royal Commission). The term "vaccinated" refers to primary vaccination only.

At Dewsbury, of 3000 exposed, 2395 were vaccinated, a

[1] Most of these data have been published in the Final Report of the Royal Commission on Vaccination.

Hosted by Google

proportion of 79·8 per cent. At Leicester, of 1234 exposed, 846 were vaccinated, a proportion of 68·5 per cent. At Gloucester, of 4861 exposed, 3386 were vaccinated, a proportion of 69·6 per cent. These proportions are somewhat altered when those who were attacked are alone considered, for amongst these there were at Dewsbury, 887 attacked, of whom 574 were vaccinated, or 64·7 per cent.; at Leicester, 320 were attacked, of whom 170 were vaccinated, or 53·1 per cent.; and at Gloucester, 1717 were attacked, the vaccinated numbering 1028, or nearly 60 per cent. Or, dealing with the *fatal* cases only, the proportions were: at Dewsbury, 83 deaths, vaccinated 13, or 16·6 per cent.; at Leicester, 17 deaths, vaccinated 1, or 5·9 per cent.; and at Gloucester, 370 deaths, vaccinated 95, or 25·7 per cent.

Distributed amongst age-periods the figures are (Tables II. and III.):—

Attack-rates and mortality.—The foregoing figures supply the means of contrasting the vaccinated and unvaccinated series in respect to their rates of attack—i.e., the proportion of those exposed to infection who contracted small-pox. They also supply data for determining the mortality (as well as the case-fatality) in each series. At Dewsbury, where the attack-rate on the whole number exposed was 29·5 per cent., the rate for the vaccinated was 24 per cent., and for the unvaccinated 51 7 per cent. At Leicester, where the attack-rate on the whole number exposed was 25·9 per cent., it was for the vaccinated 20·1 per cent., and for the unvaccinated 38·4 per cent. At Gloucester, where the attack-rate for the whole number exposed was 35 8 per cent., it was for the vaccinated 30·3 per cent., and for the unvaccinated 46·7 per cent.

Then as regards the rate of mortality, at Dewsbury for all classes, this was 2·7 per cent., for the vaccinated 0·5 per cent. and for the unvaccinated 11·5 per cent. At Leicester, where the mortality-rate for the whole was 1·3 per cent., for the vaccinated it was 0·1 per cent., and for the unvaccinated 4·1 per cent. At Gloucester, where the mortality-rate for the whole was 7·6 per cent., it was for the vaccinated 2·8 per cent., and for the unvaccinated 18·6 per cent. The case-fatality dealing with larger percentages exhibits this contrast more strikingly. Thus at Dewsbury the general fatality was 9·3 per cent., for the vaccinated 2·2 per cent., and for the unvaccinated 22·3 per cent. At Leicester, where the general fatality was 5·3 per cent., it was for the vaccinated 0·6 per cent., and for the unvaccinated 10·7 per cent. At Gloucester, where the general fatality was 21·5 per cent., it was for the vaccinated 9·2 per cent., and for the unvaccinated 40·0 per cent.

These returns may again be distributed amongst age-periods as follows (Table IV.):—

TABLE IV.

—	Attack-rate.		Mortality-rate.		Case fatality-rate.

Gloucester	30·3	40·5	4·3	21·4	13·7	53·0

The Class of "Under" Vaccination.—It has already been stated that the inclusion with the "unvaccinated" of those who were primarily vaccinated at the time of infection of the household materially influences the attack-rates and mortality amongst the former. This is most apparent in places where, as at Gloucester, such vaccination during an epidemic is widely resorted to. In order to give an opportunity to anyone to revise the foregoing returns by the subtraction of those who were "under" vaccination, as well as to give some idea of the influence which this recent vaccination appears to exert, these cases are now dealt with apart. They require, however, much closer scrutiny than can be here given, especially as to the time of the vaccination and its objective result. This has been done elsewhere, and I here must content myself with the remark that however closely they are analysed the only result of any change in the figures would be the re-transference of some to the list of the "unvaccinated," which could not fail, I think, to still further

Hosted by Google

diminish the mortality of those admitted unquestionably to be "under" vaccination. At Dewsbury, out of the 605 in the "unvaccinated class," there were 78 who may be considered as "under" vaccination when exposed to infection; of these, 21 were attacked and 3 died.[2] The attack-rate was, therefore, 28·9 per cent., the mortality 3·8 per cent., and the case-fatality 14·2 per cent. At Leicester there were exposed 17, attacked 4, and no deaths. The attack-rate was, therefore, 23·5 per cent. At Gloucester there were exposed 653, attacked 85, deaths 25, or an attack-rate of 13·1 per cent., mortality 3·8 per cent., and case-fatality 29·4 per cent.

Distributed in age-periods these figures are (Table V.):—

TABLE V.

—	Exposed.	Attacked.	Died.	Attack rate.	Mortality.	Case fatality.
Under 1 year.				Per cent.	Per cent.	Per cent.
Dewsbury	16	7	3	43·7	18·7	43·0
Leicester...	2	1	—	50·0	—	—
Gloucester	57	10	3	17 5	5·2	30·0
1 to 10 years.						
Dewsbury	41	10	—	24·4	—	—
Leicester...	8	2	—	25·0	—	—
Gloucester	550	66	21	12 0	3·8	31 8
10 to 30 years.						
Dewsbury	19	4	—	21·0	—	—
Leicester	7	1	—	14 3	—	—
Gloucester	39	8	1	20 5	2 5	12·5
30 years and over.						
Dewsbury	2	—	—	—	—	—
Leicester	—	—	—	—	—	—
Gloucester	7	1	—	14·3	—	—

Thus it will be seen that with the exception of the Dewsbury return at age "under one year" the attack rates are markedly lower than those given for the whole "unvaccinated class" at the different ages. This is strikingly the case with the Gloucester figures, where, too, the total number is very high. Similarly the mortality and fatality rates are in every instance lower than those pertaining to the whole "unvaccinated class," although mostly much higher than the rates for the "vaccinated."

Previous small-pox.—Of the 9095 persons exposed to infection in the series here dealt with, 222 were stated to have been attacked by small-pox in early life, a proportion of 2 4 per cent. Of these, 10 were again attacked, forming out of the total attacks 2922, a proportion of 3·4 per cent.; none died. The attack-rate amongst those who had small-pox a second time was, therefore, 4·5 per cent., or about one-seventh of the general attack-rate.

As regards age-distribution, a previous attack of small-pox was reported in only 2 out of the 2693 who were under 10 years of age when exposed to infection a second time, and neither of these again contracted the disease. Of the 3634 exposed to infection between the ages of ten to thirty years, 33 were stated to have had small-pox previously, and 3 of these again were infected. Of those aged thirty years and over, 187 out of the 2738 exposed to infection had previously suffered from small-pox, of whom 7 were again attacked. Thus the attack-rate for these persons who were again exposed to infection was — from ten to thirty years, 9·1 per cent.; thirty years and over, 3·7 per cent. Distributing these 222 persons between the two series of "vaccinated" and "unvaccinated" there were 146 in the former and 76 in the latter. So that the attack-rate, or liability to a second attack, was for the vaccinated 4·1 per cent., and for the unvaccinated 5·2 per cent. Of the vaccinated 17 were between ten and thirty years, of whom 2 were again attacked, or 11·3 per cent., and 129 over thirty years, of whom 1 was attacked, or 0·8 per cent. (nearly). Of the unvaccinated 2 were under ten years of age (none attacked); 16 were between ten and thirty years, of whom 1 was attacked a second time, or 6·2 per cent.; and 58 were over thirty years, of whom 3 were again attacked, or 5·2 per cent. (nearly). The subtraction of these persons, who enjoyed a much greater immunity from attack than those who had never been infected before, is essential to the endeavour to arrive at a just conclusion upon the question of the protective power of vaccination. Were this done we should have amongst the whole of those exposed 9095 minus 222, or 8873, and attacked 2922 minus 10, or 2912, giving an attack-rate of 32·8 instead of 32·1.

Similarly, the vaccinated figure would be 6627 minus 146, or 6481, of whom were attacked 1770 minus 6, or 1764, an attack-rate of 27·0 per cent., instead of 26·7. And the unvaccinated figure would be reduced 2468 minus 76, or 2392, of whom were attacked 1152 minus 4, or 1148, or an attack-rate of 48 per cent., instead of 46·6. The change wrought by this subtraction is, however, better seen in the later periods of life, where most of these figures occur. Thus, to take the age-period thirty and over only, the figures would be thus altered:—

	Exposed.	Attacked.	Attack-rate.
Vaccinated....	2619 - 129 = 2490	716 - 4 = 712	28·6
Unvaccinated	119 - 58 = 61	35 - 3 = 32	52·4

Whereas the rates at this age-period, when these persons are included, are vaccinated, 27·3 per cent.; and unvaccinated 29·4 per cent. The change is, therefore, most marked with respect to the "unvaccinated," who have been protected by having experienced an attack of small-pox in early life.

The annexed table (Table VI.) will enable those interested in this subject to make similar calculations for each of the several districts. It will be found that the attack-rate amongst the unvaccinated is everywhere much raised by the deduction.

TABLE VI.—*Showing Numbers previously Attacked by Small-pox.*

CONCLUSIONS.

Amongst the conclusions which may legitimately be drawn from the foregoing statistics are the following:—

1. That when an outbreak of small-pox occurs within a community of which the child-population is largely unvaccinated the attack-rate and mortality are highest in the early

[2] In my Report on the Dewsbury Outbreak (Appendix to the Final Report of the Royal Commission), on p. 128 et seq. these cases have been throughout separated from the unvaccinated series.

TO ILLUSTRATE AN ARTICLE ON SOME SMALL-POX STATISTICS,

BY Dr. SIDNEY COUPLAND.

Hosted by Google

Hosted by Google

years of life (under ten years). Combining the results of the three inquiries there were in all 9095 exposed to infection, of whom 2922 were attacked and 470 died—an attack-rate of 32·1, a mortality-rate of 2·1, and a (case) fatality-rate of 16·0 per cent. At ages under one year of 275 exposed 112 were attacked and 74 died—an attack-rate of 40·7, a mortality-rate of 26·9, and a fatality-rate of 66·0. At ages one to ten years of 2418 exposed, 852 were attacked and 235 died—an attack-rate of 35·2, a mortality-rate of 9·7, and a fatality-rate of 27·5.

2. That the attack- and death-rates at the age-period ten to thirty years most nearly approximate to the mean, but that the fatality-rate is lower. Of 3634 exposed, 1227 were attacked and 75 died—an attack-rate of 33·7, a mortality-rate of 2·0, and a fatality-rate of 6·1.

3. That the attack-rate at ages thirty years and over is lowest of all, but the fatality is higher than at the previous period. Of 2738 exposed, 751 were attacked and 86 died—an attack-rate of 27·4, a mortality-rate of 3·1, and a fatality-rate of 11·4.

4. That vaccination has a marked influence in diminishing liability to attack and to a fatal issue, an influence most apparent in early life, but obtaining in lessening degree at later periods, the rates amongst the vaccinated being always below those of all classes at the same period:—

TABLE VII.—*Rates among the Vaccinated.*

Vaccinated.	Attack-rate.	Mortality.	Fatality.
Under 1 year	3·2	—	—
1 to 10 years	9·3	0·2	2·9
10 to 30 years	30·6	1·1	3·5
30 years and over	27·3	2·7	10·0

5. That on the other hand, the lack of vaccination enhances the liability to attack and increases the mortality from small-pox in an infected community, both absolutely and relatively, but that the absence of this influence is less marked, at any rate, so far as regards the liability to infection, as age advances.

TABLE VIII.—*Rates among the Unvaccinated.*

Unvaccinated.	Attack-rate.	Mortality.	Fatality.
Under 1 year	45·5	30·3	66·6
1 to 10 years	46 5	13·8	29·9
10 to 30 years	57·5	9·4	16·4
30 years and over	29·4	11·8	40·0

6. That although great variations may exist between different outbreaks as regards the general attack-rate and mortality, irrespective of the proportion of the vaccinated and unvaccinated in the community, yet in every instance a similar disproportion exists in the attack-rate and mortality of the vaccinated and unvaccinated respectively. The comparison of the outbreaks at Leicester and Gloucester bears this out. In these two places the proportion of the vaccinated in the community invaded by small-pox was nearly the same, and a like parallelism obtained at each age-period. These proportions were also maintained amongst those attacked with small-pox, except that in every instance the relative proportion was higher of the unvaccinated amongst those attacked than it was amongst those exposed. The general attack-rates and the mortality at all and any age were notably higher at Gloucester than at Leicester. Nevertheless in the two places the attack-rates of vaccinated and of unvaccinated were similarly disproportionate throughout.

7. That upon this it appears that (*a*) whether a small-pox outbreak be severe or slight, intense in its virulence and fatal in its effects, or comparatively mild and yielding a low death-rate, (*b*) whatever may be the local conditions or circumstances, the amount of isolation and other less obvious factors whereby the extent of an outbreak is influenced,—there still remains one feature common to all. This is that invariably the unvaccinated members are more liable to be attacked, besides yielding a rate of fatality considerably in excess of that which results amongst the vaccinated section.

8. That the disparity between the vaccinated and unvaccinated rates is considerably increased if those who were "undergoing vaccination" when exposed or attacked be deducted from the total of the "unvaccinated," and even more markedly (for the later periods of life especially) by a similar deduction of those who had in previous years suffered from small-pox.

EXPLANATION OF THE COLOURED CHART.

These diagrams have been constructed from the statistical data given above. They are intended to furnish a ready means of comparison between the three outbreaks in respect to: (1) the general attack-rate and mortality at all ages and in each of four age-periods; (2) the proportionate numbers (per cent.) of the vaccinated and unvaccinated at all ages and at each age-period amongst those exposed to infection; (3) the proportionate numbers (per cent.) of the vaccinated and unvaccinated at all ages and at each age-period of those attacked by small-pox; and (4) the attack-rate and mortality (per cent.) of the "vaccinated" and "unvaccinated" groups at all ages and at each age-period.

(*To be continued.*)

TWO CASES OF INTRACRANIAL TUMOUR.

BY F. W. EURICH, M.B., C.M. EDIN.,
LATE PATHOLOGIST, COUNTY ASYLUM, WHITTINGHAM, LANCASHIRE.

INTRACRANIAL tumours form but a small percentage of the cases occurring in asylum practice. Their comparative rarity has frequently been commented upon, the more so as such an institution is the haven in which only sufferers from intracranial diseases or their results find refuge. The effects and manifestations of tumour-growth have usually been divided into those of a local and of a general nature. The former are very rarely such as to render the patient's removal to an asylum advisable, while the mental disturbances included among the latter are usually of a simple nature, such as dementia of varying degree, with or without stupor, or slight melancholia readily controllable at home or in hospital. Occasionally, however, a different tale can be told; and it is my present purpose to illustrate some of these more unusual features with the help of a couple of cases which have, among others, come under my notice as pathologist during the past year.

CASE 1. *Epilepsy (?); tumour of the frontal lobe.*—The first case, for the clinical notes of which I am indebted to my colleague, Mr. C. Bayley, is that of a man aged fifty-five years, admitted into Whittingham Asylum on March 28th, 1895, and who died therein on Sept. 19th of the same year. The certificate on which he was admitted states that "he has delusions of identity, time, and place; that he cannot give any connected account of himself, wanders about on imaginary journeyings, and has no idea where he is or when he came here." Historical particulars are very scanty. He is said to have suffered from two previous attacks, but the age at which they occurred, their duration, and other details are returned as unknown. Notes as to family tendencies and previous bodily health were not forthcoming, while the man's mental condition precluded the possibility of his giving a reliable account of himself. He volunteered the statement that he suffered from fits, and the facts mentioned in the certificate could certainly be interpreted to that effect, but he could not tell how long he had been so afflicted, when they seized him, or whether he had an "aura" or not. He was distinctly demented, his apperception being slow and his memory, for recent events in particular, impaired, but there was no sign of stupor. He presented delusions of identity, time, and place, as mentioned above, and was obstinate, bad-tempered, and passionate, displaying the common "epileptic character." He would at times make rushes, attempting to strike those about him or to smash surrounding objects. He was careless as to his person and took no active interest in what was going on around him. When I saw him he was reading with some intelligence a weekly periodical of light literature; in conversation his sentences were well-formed and his utterance distinct, but he was sullen and showed a disinclination to talk. Particularly was there no sign of aphasia in any of its forms. Physically he was well-nourished, somewhat sallow complexioned, with dilated capillaries on the cheeks and nose, and glistening sclerotics. The pupils were contracted, reacting well to light and

Hosted by Google

accommodation. There was no optic neuritis. The reflexes were all normal; there was no motor or sensory impairment. The pulse was 70 and the respiration 19. He ate and slept well and seemed in fair general health, with the exception of a troublesome cough. His condition remained the same till the beginning of August, when the cough grew worse, a slight rise in the temperature was registered in the evenings, and he took to his bed. Physical examination only revealed the signs of chronic bronchitis. At the end of August he had an attack of hæmoptysis; he became feeble and emaciated, and his respirations became shallow and very rapid (60 per minute). Cheyne-Stokes respiration was noted towards the close and he died on Sept. 19th, 1895. At the necropsy there were found, besides chronic bronchitis, scattered patches of broncho-pneumonia, and an abscess cavity (non-tuberculous) in the left upper lobe, the following conditions:—The calvarium presented nothing of note; the dura mater was somewhat thickened and tense; on opening it the subdural space was dry and the subjacent convolutions slightly flattened. On attempting to remove the brain it was found to be attached to the floor of the anterior fossa by a tumour. Involving the dura mater and the pia mater, over the anterior and inferior aspects of the left frontal lobe, but leaving the bone untouched, the tumour had invaded the left frontal lobe penetrating as far as the head of the caudate nucleus. The falx was adherent to the mesial aspect of both frontal lobes and was likewise involved by the tumour which, passing through it, had attacked the adjacent cortex of the right lobe. The corpus callosum had also become infiltrated for about an inch. The tumour was not encapsulated and could not be shelled out; it was reddish-white, with a peculiar soft, granular aspect on section and of fairly firm consistence. The white matter of the hemispheres in its immediate neighbourhood had softened, which softening extended to the anterior edge of both optic thalami, the ependyma, which was granular, alone separating it from the cavity of the lateral ventricles. The basal arteries were slightly atheromatous; with this exception the rest of the brain presented nothing of any interest. There were no secondary deposits in any part of the body.

CASE 2. *General paralysis simulated; apparent convalescence; relapse; multiple psammomata of the dura mater.*—The second case (clinical notes of which have been kindly supplied by my colleagues, Dr. A. Simpson and Mr. R. J. Stephens) is of peculiar interest and in some respects perhaps unique. It is that of a woman, aged thirty-eight years, who was admitted into the asylum on Nov. 23rd, 1894, and died on July 10th, 1895. The reception order states that "she is sullen, morose, and stupid; she curls herself up under the bed-clothes and refuses to answer questions and to take food. She is excited at times and with difficulty restrained. Her husband is afraid that she will do away with herself." The somewhat meagre history said that she was married and had three children, the youngest one year old. Her parents died from phthisis and one brother committed suicide. She had been of temperate habits and, with the exception of an attack of typhoid fever some years ago, had always enjoyed good health. The present attack was stated to be of nearly three years' duration, consisting of progressive dementia. On admission she presented the appearance of a full, flabby-faced woman, almost suggesting œdema, expressionless, and with a generally bloated look. The pupils were contracted and did not react to either light or accommodation. There was neither optic neuritis nor atrophy. The reflexes appeared to be normal. Speech was so thick, indistinct, and slurred that even the pronunciation of her name was almost unintelligible. Muscular power was much impaired without any definite paralysis and she was sent to bed immediately after admission. Any sensory defects that might have existed could not be ascertained on account of her mental condition, though she appeared to be sensitive to pain. She was extremely fatuous and demented, lying in bed dull, listless, and uncomplaining, not seeming to appreciate where she was or to have any idea of her surroundings. She lay grinding her teeth, passing urine and fæces into the bed, and required every attention. At times she was restless. She was considered to be a general paralytic in the third stage, and the progress of the case for some time justified this opinion. From Dec. 1st to Dec. 4th she had an irregular febrile temperature, was lethargic, and could scarcely swallow. On Jan. 3rd, 1895, she had a slight epileptiform seizure affecting mainly the left side, and was more helpless and feeble. But now a remarkable change took place; the patient began to improve. On Jan. 20th she was reported as being slightly better, but very helpless still. On Feb. 4th the note says that she smiled fatuously when spoken to and appeared to understand more of what was going on around her. On Feb. 27th she was just able to sit up and was much brighter mentally. The favourable change progressed till at the end of April she was able to get about, though her face was still expressionless, her speech still somewhat slurred, and her manner childish and demented. In June she was reported as bright and cheerful, working well in the ward, and greatly improved as regards her general health. In fact, she was considered sufficiently convalescent to be discharged to the care of her friends. General paralytics, we know, may improve unexpectedly and to such an extent that their detention in an asylum is no longer warranted; but such an improvement as this woman, presumably in the third stage of general paralysis, showed has never yet, to my knowledge, been recorded. The diagnosis was therefore re-considered, but a better one was not arrived at, for convalescence was quite as unaccountable in any of the diseases which might possibly have simulated general paralysis. She was, then, to be discharged and the diagnosis suspended *sine die*, as it were; but on June 27th, a day or two before she was to have left us, a sudden change occurred. She was noticed to be looking dazed and ill and complained of severe occipital headache. This was the first occasion, be it noted, on which headache was complained of. She was sent to bed. The temperature was sub-normal, the pulse 84, and the respirations 19. There was no vomiting. The pupils were equal and contracted and showed a peculiar phenomenon. When the lids were raised by the examiner the pupils dilated to their utmost capacity, but after a few seconds contracted, or rather collapsed, with rapidity, only to dilate again after an interval of perhaps a minute previously to again contracting. This would be repeated periodically and apparently quite independently of the action of light or accommodation. The knee-jerk was absent, but the other reflexes were normal. During the following days the headache increased in severity. It was then I saw her for the first time and observed the conditions already noted. In addition, I found her crouched up in bed moaning, with injected conjunctivæ. Sensory aphasia (?) also appeared to develop as far as could be ascertained in her condition; she was easily roused and could well express her wants, but did not seem to understand what was said to her. She became more and more stuporose; there was slight rigidity of the muscles at the back of the neck; and a few days before death loss of power was detected in the right arm and some paresis of the right side of the face, while the leg remained apparently unaffected. No convulsive seizures were noted. She rapidly became comatose; Cheyne-Stokes respiration developed, and she died on July 10th, thirteen days after the onset of acuté symptoms. The post-mortem examination revealed a startling condition of affairs. The dura mater was thickened and firmly adherent to the calvarium over the left hemisphere from the Rolandic fissure backwards. On carefully opening it a large number of almost spherical tumours were found growing from its inner surface on the left side. They attained their maximum development over the ascending parietal convolution, the whole parietal lobe, the upper half of the temporo-sphenoidal lobe, and over the mesial aspect of the hemisphere from the Rolandic to the calcarine fissure, in which region they were so densely clustered as to give rise to mutual compression. They were about thirty in number, ranging in size from the dimensions of a walnut to those of a green pea, the larger variety predominating. They merely compressed the hemisphere, in no wise implicating the cortex, being only here and there loosely attached to the pia-arachnoid. The corpus callosum and the mesial aspect of the right hemisphere were necessarily somewhat compressed. Not all the tumours were so clustered together; one or two were noted at more distant sites. A few of small size were found growing from the dura mater of the base in the left middle cerebral fossa, a large solitary growth on the dura mater covering the anterior surface of the left frontal lobe, and another of the same size springing from the posterior margin of the large wing of the right sphenoid bone. The tumours, covered by a thin, tense capsule, were pinkish-yellow on section, of a soft, fibrous structure, and slightly gritty to the touch. Their attachment to the dura mater was not particularly firm, a soft, felt-like base being left behind.

Hosted by Google

The bones of the skull were not affected. The direct effects of compression of the cerebral cortex were very marked, the grey matter being often reduced to a thin, dark greyish-purple line. Elsewhere the cerebral cortex, though a little congested, appeared healthy, particularly without even a suggestion of general paralysis. The membranes stripped readily; the lateral ventricles showed no granularity or dilatation; in fact, the rest of the brain presented no obvious morbid appearances.

Widely as these two cases differ from each other they have yet two points in common. One is the predominance of mental over bodily symptoms already referred to in the introductory remarks—dementia, with more or less excitement, being the form assumed. The other is the absence of headache, of optic neuritis or optic atrophy, and of vomiting. It is, however, such a well-recognised fact that these three cardinal symptoms may occasionally be wanting that it will suffice if I record it and pass to other points in the diagnosis. The facts of the first case are scanty. The patient was a quarrelsome, impulsive dement, possibly an epileptic, though no fits were recorded during his detention at Whittingham Asylum. All signs of intracranial pressure or of a distinct focal brain lesion were absent. The existence of the Cheyne-Stokes phenomenon was practically valueless and the only suspicious circumstance was the alleged epilepsy, as true "idiopathic" epilepsy rarely develops in the sixth decade. But cortical or subcortical thrombotic softenings are a frequent cause of epileptiform seizures at that time of life, and this consideration, together with the general aspect of the man—the glistening sclerotics, the dilated facial capillaries, and the chronic bronchitis—gave some colour to the supposed existence of such localised areas of softening. Apart from the question of diagnosis, some interest attaches itself to the site of the growth in this instance and to the symptoms manifested by it. Epilepsy—not Jacksonian—is of not infrequent occurrence in tumour of the frontal lobe and is apparently the effect of indirect irritation and pressure; the case is another instance of this, and in this respect presents nothing unusual. Far more interesting is the relation of the tumour to the frontal lobes as the seat of the higher organs of mind. Attempts have been made to assign distinctive clinical phenomena to morbid growths in this region. Marked enfeeblement of the mental powers has been credited with some diagnostic importance, but cases have been published in which great deterioration of the intellect has accompanied tumour growth elsewhere, whilst mine shows that a neoplasm may extensively invade one frontal lobe, may involve the other together with the corpus callosum, and yet give rise to only a moderate degree of mental failure. Bruns, who, in opposition to Ferrier, Allen Starr, and others, is not inclined to attribute to the frontal lobes a greater share in the higher intellectual faculties, might cite this case in support of his views; but another interpretation seems also possible. The tumour, as microscopic examination (see later) showed, was evidently of slow growth—allowing, maybe, the more intact right lobe to compensate to some extent the lesion in the left—and might have gone on growing for a further considerable period as far as the effects produced by it were concerned, had not an intercurrent disease cut short the patient's life. Now the rapidity with which an intracranial tumour runs its course in the absence of complications will depend upon its site and nature, while the multiplicity and severity of the symptoms manifested will, *inter alia*, depend upon the rapidity of its growth. A cerebellar hemisphere may, for example, be almost totally destroyed by an abscess of gradual formation, with no symptoms to point to such a lesion. Similarly, we have to deal in the present instance with a tumour which, by slowly destroying, rather than by compressing, the nervous structures had failed to increase the intracranial pressure to any great extent. We may, therefore, consider that the tumour had reached but a comparatively early stage of its life-history at the time of the patient's death. If this be granted, then the case is of value as corroborating the opinion lately put forward by Oppenheim and others, that tumour growth in the frontal lobes anterior to the præcentral gyrus is often characterised, not by the extent of mental impairment, but by the early onset of the same, frequently even before sensory or motor symptoms become manifest. The epileptic seizures alleged to have occurred in Case 1 must not be placed in the latter category—at least, not in the sense here employed; general epileptic convulsions are in such cases not a local manifestation, but as much a general symptom of organic brain disease as headache, vomiting, or a slow pulse. Whereas no suspicions as to the presence of a cerebral tumour were entertained in the first case matters were somewhat different in the second. For the sake of convenience we may consider the diagnosis in connexion with three distinct periods in the course of the disease—viz., on admission, at convalescence, and at the occurrence of the relapse which ended in death.

The difficulty on the first occasion lay in the intensity of the symptoms presented, while headache, vomiting, and optic neuritis were absent. True focal symptoms were also wanting, profound dementia, general paresis of the extremities and helplessness, with difficulty in swallowing and unintelligible articulation, being the most marked objective phenomena. Some fine distinctions have been drawn between the dementia of general paralysis and that of cerebral tumour; between the affections of speech in the two diseases; and between the modes of onset and the relation to each other of mental and motor symptoms. In cases of cerebral tumour the dementia is said often to assume the form of childishness; speech is said to be slow, thick, and laboured, and not so ataxic as in general paralysis, while motor symptoms are said to manifest themselves sooner than mental. Other and finer points of difference are said to exist; but, like the foregoing, they can only be of use in the diagnosis of cases not too far advanced. Progressive destruction of the cerebral cortex, whether due to a diffuse new growth or to the process underlying general paralysis, must gradually merge initial differences into the final and more or less uniform picture of loss of cerebral function. In no class of diseases is the knowledge of the mode of onset and development of symptoms so valuable as in affections of the nervous system. The paucity of historical particulars in the present instance was most unfortunate, depriving us, as it probably did, of important criteria. Two facts only in this period of the disease may be noted as exceptional if the case was one of dementia paralytica—namely, the absence of pupil reaction to both light and accommodation and the apparently normal condition of the knee-jerk. Both are uncommon in general paralysis; still, their comparative rarity was insufficient in itself to imperil the diagnosis. Then came that remarkable period of convalescence, during which the diagnosis "general paralysis" had to be re-considered. We have already stated that convalescence in the third stage of general paralysis is unknown, and that the diseases which could simulate general paralysis—namely, cerebral tumours, cerebral syphilis, "colloid disease" of the hemispheres, multiple sclerosis, lead paralysis, and other toxic conditions—all present the same difficulty. It is true that in multiple sclerosis some symptoms—e.g., oculo-motor paralysis—may disappear, and that others, such as dementia, may show some temporary improvement; but the absence of all other symptoms, such as tremors, nystagmus, &c., practically excluded it. None of the remedies deemed serviceable in some of the above had been employed, especially had mercurials and potassium iodide at no time been exhibited, treatment having been mainly expectant. Syphilis and lead-poisoning could, therefore, probably be excluded; of the latter there was, moreover, not the slightest indication elsewhere. Alcoholism was most unlikely, as she was stated always to have been temperate, as well as for other reasons. She was too young for that very rare affection "colloid degeneration" of the hemispheres, and pachymeningitis interna hæmorrhagica was most unlikely to occur at her age save as a complication of general paralysis. So only two diseases remained—general paralysis (with or without pachymeningitis) and intra-cranial tumour. Convalescence was in each case equally inexplicable, though we know that some tumours—sarcomata and psammomata among them—may undergo temporary involution under certain conditions, notably during the puerperium. There was nothing, however, to make us believe in such a remote possibility, and so the diagnosis was suspended for the time being. But on the occurrence of the relapse and the sudden onset of acute symptoms the question of diagnosis again came to the front, and the problem was to decide between an exacerbation of a hæmorrhagic pachymeningitic process, a "paralytic" seizure, meningitis of the vertex, or sudden increased tension in a cerebral tumour. The course of the disease, the steady progress from bad to worse without the occurrence of convulsions, practically excluded a "paralytic" congestive attack. No possible cause could be assigned for an acute meningitis (except a

Hosted by Google

tumour), quite apart from the fact that the temperature never rose above normal. There were thus left, as alternatives, a pachymeningitis hæmorrhagica or an intra-cranial growth. Both give rise to pressure-effects, both are of local origin, capable of causing focal symptoms, and both are liable to sudden increase in tension. If the case was one of pachymeningitis, then the possibility would gain ground that general paralysis was present after all—the third stage of that disease being simulated by the complicating meningitic process, while convalescence might have been brought about by the brain becoming accustomed to a pressure which had ceased to increase and which had possibly even diminished from some organisation and absorption of the effused blood. Whatever the nature of the brain-compressing tumour its position was clearly at or near the psychomotor areas of the left hemisphere. One fact, however, appeared difficult of interpretation: we refer to the left-sided epileptiform convulsion which had occurred some six months previously. A few isolated cases in which convulsions and paralysis have occurred on the same side as the cortical affection have, it is true, been reported by reliable authorities, but the more natural explanation in this case was to assume the bilateral nature of the lesion, differing probably in severity on the two sides, but yet in symmetrical positions. The lesion that most commonly fulfils these conditions is hæmorrhagic pachymeningitis. We therefore formulated our diagnosis to this effect: that the patient was suffering from cerebral compression, due in all probability to bilateral hæmatoma of the dura mata, complicating general paralysis. Further remarks on the case are, I think, superfluous. The only remaining point of interest would be the explanation of convalescence. The cortex of the left hemisphere—at least, a great part of it—was compressed and atrophic to such a degree as to indicate a process of some standing. The right hemisphere in all probability stepped in and gradually undertook some of the functions of the left, aided by a temporary cessation of growth in the tumour, and possibly by diminished tension; then sudden, increased vascular pressure may have rapidly brought about the fatal termination.

I have so far only considered the clinical aspect of these cases; a word or two concerning the microscopic appearances of the tumours may not be amiss. The first tumour was composed of masses of ovoid cells which were here and there arranged in strands separated by bloodvessels. It was microscopically sharply defined from the brain substance, into which it sent delicate, bud-like processes, rich in vessels, and gave us the impression of having sprung from the endothelial cells of the dura mater. The principal feature of interest was the presence of certain spherical bodies irregularly distributed throughout the tumour. They were, curiously enough, more plentiful in the younger parts of the growth, where they were frequently clustered together with just a few tumour cells intervening. Round their outer margin, which was clearly and sharply defined, one or two delicate spindle cells could almost invariably be seen and sometimes just a trace of fibrous tissue. These bodies took up various stains in various ways—some were dyed red, others yellow with picro-carmine, some light blue, others almost black by hæmatoxyline; alum carmine stained them in every shade of purple, while eosine gave them a fine pink tint. With iodine they assumed a golden yellow colour and no "amyloid" reaction could be obtained by any of the usual methods. Though the majority of these "corpora" were devoid of concentric striation, yet a goodly proportion showed it in various degrees. Calcification was not apparent. Here and there—instead of a spherical body—an elongated, curved, rod-shaped structure could be noted, fractured transversely in places and responding to staining re-agents in all respects like the former. A double process appeared to underlie the formation of these bodies; the greater number of them appeared to have resulted from a sort of obliterative endarteritis leading to occlusion of the vessel and ending in a degeneration of the inflammatory products—perhaps a form of coagulative necrosis. The other process, which, however, plays a very subordinate *rôle*, is a hyaline degeneration of the vessel-wall; it is limited to the periphery of a few of the bodies and forms a thin ring there. I have stated that in the older portions of the growth the tumour-cells were separated into strands by intervening vessels. This formation is much accentuated by the fact that nearly all these vessels present an advanced stage of hyaline degeneration; their walls are often ten or more times as thick as in the normal, have here and there almost occluded the lumen, and have pushed the tumour-cells aside. In one or two places only scattered remnants of the latter have survived, and all that can be seen is a mass of hyaline material, the vascular origin of which is recognisable only on closer examination and best by means of eosine-staining of formol-hardened specimens, in which the well-preserved red blood-corpuscles are conspicuous by their brilliant scarlet. If the areas illustrating the first process were to be alone submitted for examination one would probably be inclined to name the tumour a "psammoma"; if the areas demonstrating only the last, a "cylindroma." But we have here a mixture of the two; and it would appear that vessels which have become subject to the hyaline change to any extent are exempt from the endarteritic process and *vice versâ*. Why this should be we do not know and do not wish to speculate. Curiously enough, the tumours in Case 2, which were composed of long, almost fibrous spindle-cells, presented to some extent a parallel. The older growths contained a multitude of spherical bodies similar to those in the last case, but mostly calcified, and presenting besides an almost constant concentric lamination, also a delicate radial striation in some few instances. Treatment with hydrochloric acid of such bodies as were not too old revealed what appeared to be the remains of nuclei; and in the tumours of younger formation a process of obliterative endarteritis could again be noted, evidently the precursor of the "sandy" bodies. Neither in this case nor in that of Case 1 was there any evidence that the spheres resulted from the conglomeration of tumour cells. I have ventured to enter into these details as the classification and nomenclature of such tumours are still in a lamentable state of confusion. I do not pretend to say that all so-called "corpora amylacea," "corpora arenacea," &c., are the results of an endarteritis; two cases would be obviously insufficient for such a statement. But I am strongly of opinion that the terms "psammoma," "cylindroma," &c., are misleading. The structures from which these names are taken may occur in tumours of diverse characters—e.g., in mammary carcinoma, in ovarian, parotid, and omental tumours, as well as in tumours of the brain, and may even, as the first specimen showed, appear side by side in one and the same neoplasm. Those that result from endarteritis are perhaps the expression of a "senile" change in tumours of slow growth. Their greater frequency in some tumours than in others would appear to depend upon the differences in the rate of growth, which is, again, dependent, not only on the variety of tumour, but on the site of development; hence the difference of opinion whether a "psammoma" should be ranked among the sarcomata or whether it should constitute a class of its own. I am of opinion that these tumours do not constitute a special class, and that if the terms are to be used at all they should be employed in the adjectival form, such as "psammomatous sarcoma," "psammomatous glioma," "cylindromatous endothelioma," &c. "Angiolithic sarcoma," a name suggested by Cornil and Ranvier for certain forms of growths, would similarly have its advantages.

Whittingham.

TWO CASES OF ECTOPIC GESTATION IN WHICH RUPTURE OF THE SAC TOOK PLACE IN THE THIRD WEEK; ABDOMINAL SECTION IN ONE CASE; RECOVERY.

BY HASTINGS GILFORD, F.R.C.S. ENG.

RUPTURE of the sac of an ectopic gestation under the age of one month is statistically very uncommon. Thus of 300 instances of this accident collected by Hecke and Cauenbirge[1] only two were at this period, one being of three weeks' duration and the other of fifteen days. Parry[2] out of 174 cases of rupture gives one which occurred at three weeks, and states that "the earliest period mentioned is three weeks," but afterwards goes on to say that "Rokitansky has known rupture to occur within a fortnight after conception." In the experience of Mr. Lawson

[1] American System of Gynæcology, vol. ii., p. 184.
[2] Extra-uterine Pregnancy, p. 174.

Hosted by Google

Tait[3] "the period of rupture is limited between the fourth and twelfth weeks of pregnancy." Very few instances are reported in medical literature. In some of them it is difficult to ascertain the duration of pregnancy even when an examination of the sac has been made, owing to the loose standard of measurement made use of. Thus Dr. Montgomery[4] has published a case in which a cyst "of the size of a cherry" was found in the left tube at an operation for a rupture which occurred five weeks after menstruation. One which was estimated to have been of three weeks' duration is also reported by another observer, who writes that the sac was of the size of a hazel nut. Dr. Richards of Mass.[5] in publishing a case, which he also computed from the date of the last menstruation to have been of three weeks' duration, found the right Fallopian tube dilated to the size of an olive. Dr. Martin[6] describes a case in which the sac was of the size of a pigeon's egg and in which the period of pregnancy was estimated to have been about four weeks.

Now comparisons of this sort are almost necessarily inaccurate owing to the fact that people vary widely in their estimates. Thus I have known the size of one and the same growth to be compared by one observer with a walnut, by another with a cobnut, and by another with a pigeon's egg. And when such estimates are brought to the test of actual measurement it is surprising how wide of the mark they are sometimes found to be. Moreover, many of these common domestic articles vary greatly in size. Some varieties of cherries or of nuts are almost double the size of other varieties, and olives probably vary as widely. The average length of some hazel nuts that I measured was 17 mm., and of some cherries nearly the same. Waldeyer,[7] who measured an ovum and membranes of the age of "exactly four weeks," found the length to be 19 mm. It is therefore probable that the age of three weeks assigned to the first and second of the above cases was approximately correct; but in the case of the third, if the enlargement were due solely to the ovum and its membranes, the estimate of three weeks must be wrong, for an olive measures 30 mm. in length. If ample allowance be made for the thickness of the sac wall the ovum could not have been under the age of a month; nor is it likely that a sac the size of a pigeon's egg could have been of only four weeks' growth, for the egg of the common blue rock has a length of 36 mm. This is midway between the 42 mm. of the wood pigeon's and the 30 mm. of the turtle dove's. The mistakes which may arise from this vague method of measurement are well shown in some estimates attributed to Smolsky and which I have seen quoted in more than one publication with approval. He is said to have observed that the sac of a tubal pregnancy reaches the size of a pigeon's egg during the first month, while at the end of the second month it approximates to that of an English walnut; in other words, the length of the pigeon's egg being 36 mm. and that of the common English walnut 32 mm. (it varies from 26 mm. to 38 mm.), the sac is no larger at two months than it is at one month!

But the opinion now held by gynæcologists is, I believe, that rupture under the age of one month is by no means so unusual as the older statistics lead one to suppose. Recent statistics of German writers show a much larger proportion of ruptures at this early period, and there are reasons for believing that many cases are undiagnosed. 1. In the first place, the fact that the diagnosis of ectopic gestation is commonly based on the presence of one or more of the symptoms of pregnancy may become positively misleading when we have to do with a case in which they have not had time to develop. 2. Then certain other symptoms, which are common to all cases after the lapse of a month, may before then be absent, particularly alteration in the character of menstruation and pain.[8] 3. Mistakes may also arise from the absence of a tumour. The sac in these early cases is so small as to be unrecognisable by external examination. In my second case I was unable to find the sac even before rupture, though I examined the Fallopian tubes carefully. 4. There is another sign which is so often present that its absence may be a special source of error. This is hæmatocele. It is so customary now to associate pelvic hæmatocele or hæmatoma with the rupture or abortion of the products of an abnormally situated pregnancy that there is a tendency to regard the one as the necessary concomitant of the other. Indeed, while in most text-books a bulging of Douglas's pouch is given as a consequence of rupture, no mention is made of the fact that this important symptom may be absent. One probable result of this serious omission is that some of these cases remain undiagnosed owing to the fact that there is no local sign of pelvic hæmorrhage. In neither of the following cases was there any evidence of a collection of blood in Douglas's pouch, though in one there was a small swelling in the broad ligament. This symptom was also absent in another case I once saw, in which rupture took place at the end of the ninth week, and in which the patient made a marvellous recovery after being seemingly in articulo mortis. Absence of one of the above factors may render diagnosis difficult; but when, as in one of the following cases, there is no indication of pregnancy, no sign of a tumour, and no obvious collection of blood in the pelvis, and in which all the symptoms are abdominal and not pelvic in character, an exact diagnosis is hardly possible. These two cases afford a good illustration of the rule that the indications of rupture are almost as severely fulminating in character in those of early as in those of later date. Mr. Bland Sutton,[9] who has thrown so much light on this subject, writes of an instance in which intense collapse ensued on the rupture of a sac containing a tubal mole of 8 mm. long. But it is asserted by others[10] that the symptoms may be quite insignificant. I have, however, been unable to find the report of any such case except one which has also been published by Mr. Bland Sutton in which the sac was ruptured at about the third week and the symptoms were slight.

CASE 1.—A woman, aged twenty-eight years, who had had a natural labour two years previously, sent for me to attend her for a supposed miscarriage. I found that the last menstruation had commenced seventeen days before and had run its usual course in four days. The next day, however, the flow returned and continued without cessation up to the time I saw her. It was small, but variable, in quantity, and was neither shreddy nor attended with pain except the usual sacral aching that she always felt when "unwell." She herself was convinced from her feelings that she was pregnant, but there were no other indications of pregnancy. On bimanual examination I thought the uterus was somewhat large, but a careful examination of the ovaries and tubes failed to reveal anything amiss. Connexion had last taken place two days before the period and not for about a fortnight before. I attached much importance to her own indescribable feelings of having conceived, and looking upon the case as one of very early abortion thought of dilating the os and curetting. The next day, however, under the influence of rest in bed, both backache and bleeding ceased, and on the seventh day she went downstairs. On the evening of this same day she had risen from a sofa, and was on her way to the kitchen when she shrieked out with a dreadful pain in the left iliac region and dropped down in a faint. At the same time the uterine bleeding returned, but finally ceased in a few hours. When I saw her about an hour afterwards she had been sick and was of a deathly pallor, while her skin was covered with a cold clammy sweat. The pulse was small and too frequent to be counted. She, however, speedily improved under the influence of a small dose of opium, and I left her fairly comfortable in bed, with directions that I should be sent for if the symptoms returned. No examination was made for fear of inducing fresh local bleeding. Early the next morning I received a message from the husband, saying that she had "passed a terrible night, vomiting and fainting the whole time. Is extremely weak; she seems utterly to have collapsed." I now made a vaginal examination, but the universal tenderness and rigidity of the abdomen were such as to render a satisfactory investigation impossible. I could detect no swelling and the uterus was freely moveable. It was decided that if she did not speedily improve an operation would be advisable. She had, however, no fresh symptoms, and three days after the accident was so much better than she looked and felt almost as well as before it occurred. I now very carefully made a vaginal examination and detected a hard, round, and moveable swelling in the left

Hosted by Google

broad ligament. It seemed to be about 20 mm. long and was tender on pressure. Its inner end was close to the uterus, but the two could be differentiated by the finger. During the reaction from shock the temperature rose to 100·5° F., but it soon dropped to 99·5°, and did not again rise higher, though it was more than six weeks before it became permanently normal. The swelling gradually diminished in size, but did not disappear until after the lapse of nearly three months.

CASE 2.—This woman was aged thirty-three years and had been married thirteen months. Nine months before she had miscarried of a three months' child and had been very ill with fever and offensive discharge until the products of conception came away. Menstruation then became regular but painful. She menstruated fourteen days before the accident in the usual manner, but was a week over her time. On the evening of Aug. 22nd she ate a quantity of unripe plums. At 9 P.M. she was straining at stool when she felt as if something gave way in the "small of her back." This was instantly followed by such shock and agonising pain in the abdomen that she had great difficulty in getting to her bedroom. Dr. Abram was now sent for, and when he arrived she was retching and vomiting almost incessantly, and was complaining of intense pain, mainly referred to the regions of the sternum and shoulders. It came on in paroxysms and was accompanied with faintness and increasing feebleness of pulse. Her extremities were cold and lips blanched, and she tossed about in perpetual restlessness. The temperature was subnormal. The abdomen was full, but not distended, and was uniformly tender except in the epigastric region, where it appeared to be more sensitive than elsewhere. The following day the abdomen was fuller and a shifting dulness was noticed in the left flank. A bimanual examination revealed nothing to account for her symptoms. Dr. Abram considered her condition to be the result of hæmorrhage and asked me to see her with the view of performing abdominal section. We found it impossible to arrive at a satisfactory diagnosis. Dr. Abram inclined to the view that there might be a perforated gastric ulcer attended with hæmorrhage. This opinion was supported not only by the mode of onset, situation, and character of the symptoms but by the fact that they had set in apparently as the result of a highly injudicious meal. I, on my part, supposed from the quantity of fluid that was evidently present in the abdomen that the symptoms were, perhaps, due to the twisting and rupture of a latent ovarian cyst. We both agreed that in the event of the continuance of the symptoms the patient's chances of recovery would be improved by an exploratory incision. Late in the afternoon, as there was no improvement, we decided to operate. On opening the abdomen between the navel and the pubes a rush of dark blood took place through the wound. On inserting the hand the fingers came down upon a pedunculated fibroid situated in the fundus of the uterus. It was round, of about 40 mm. in diameter, and was broken off without bleeding. The middle of the left tube was then found to be expanded into an oval swelling 12 mm. in length and split along its upper surface for nearly its entire length. Its inner surface was shaggy and its walls averaged about 2 mm. in thickness thinning off to a paper-like tenuity at the edges of the rent. No bloodvessels could be seen, nor could a probe be introduced into the expansion from either end. The rest of the tube appeared to be healthy and was neither constricted nor dilated and the fimbriated extremity was open and unaltered. The ovary was slightly enlarged and was afterwards found to contain a recent corpus luteum. The right tube and ovary were found to be healthy. The left were both removed after the application of a silk ligature. The abdomen was flushed out with boiled water. The blood and imperfectly formed clots probably amounted to more than two litres. The washings were unfortunately thrown away by mistake before they had been inspected for the ovum. The stomach was examined but no ulcer was found. No drainage-tube was used. The patient did well until the fifth day, when the temperature began to rise. It became progressively higher until the tenth day, when there was a discharge of pus into the rectum, and from that time the patient made an uninterrupted recovery.

Remarks.—Case 1 was seen on the third day by a very able gynæcologist, who pronounced it to be one of simple para- and peri-metritis, basing his opinion chiefly on the absence of the indication of pregnancy. But I consider this a good instance of the way in which these early tubal ruptures may be overlooked. I myself now know that I once made a similar mistake. A woman came to me three months after a "miscarriage" subsequent to amenorrhœa of six weeks' duration. It was attended with very severe symptoms, which, she said, were attributed by the medical attendant to the fact that "nothing ever came away," though it appears that there was bleeding from the uterus of three or four days' duration. I found the uterus to be embedded in a plaster-like mass, which I thought consisted of distended tubes and ovaries matted together with inflammatory material. She subsequently went into a hospital but came to me again on her discharge. That which I took to be inflammatory material had then disappeared, and the uterine appendages were distinctly swollen and painful. At the operation which I afterwards performed both tubes were found to contain blood, one being distended like a sausage, while in the other it was circumscribed into a rounded cyst of about 30 mm. in diameter. I greatly regret that this specimen was subsequently thrown away, for I now think it may have been an instance of double tubal pregnancy, though the way in which one tube was distended for nearly its whole length with clot is suggestive of some other cause for the hæmorrhage in one side. That which I regarded as the effusion of pelvic cellulitis I now suppose was really coagulated blood. The case was a lesson to me on the pathology of some cases of so-called parametritis.

In Case 1 detailed above it may well be asked if it were not an instance of incomplete tubal abortion, but the fact that the swelling was apparently at the uterine end of the tube was against this assumption. Moreover, all such cases should surely be classed under the head of rupture unless there is ocular proof that blood has found its way into the peritoneal cavity through the mouth of an unruptured tube. It is well known that Mr. Lawson Tait is sceptical of the possibility of a true abortion from the Fallopian tube comparable with that from the uterus. Certainly in some of the cases which have been brought forward by the Germans as instances of tubal abortion it is distinctly stated that the tube was torn. I prefer to look upon this case as one in which there were either successive gushes of blood through a rent in the sac or into a small adventitious sac in the broad ligament. In the former case the nodule felt by the finger would be a tubal mole or hæmato-salpinx; in the latter a hæmatoma. Although there was no direct evidence of the effusion of blood into the peritoneal cavity, yet the symptoms were so much more consistent with this hypothesis that I have no doubt it was what actually took place.

With regard to Case 2, in some books it is stated that the bulging of a hæmatocele may not be felt at an early period owing to the blood being in a liquid condition; but in the course of a few hours, when coagulation has set in, it will be evident. But that this is not the explanation in all instances is well shown in the case under notice, for it was found at the operation that nearly all the blood, both clotted and fluid, came from the left flank and that not so much as an ounce was found in the retro-uterine pouch, though there were no adhesions to prevent its reaching this situation. Probably when rupture took place the blood immediately dropped into the most dependent part, which then happened to be Douglas's pouch; but afterwards, when the patient was on her side, it shifted into the left flank, being helped on its way by her restlessness. Subsequently it was kept from again getting into Douglas's pouch by the distension of the intestines. This is similar to what is observed in perforated gastric ulcer and other accidents in which fluids are poured into the peritoneum. And every surgeon who has irrigated the abdominal cavity knows how difficult it sometimes is to get fluid to pass the barrier of neighbouring coils of intestine when they are distended with flatus. The accident occurred in this case apparently as the result of straining at stool, but it is quite possible that a slight rupture had really taken place before and was the cause of the desire to defecate, for the patient did not actually get relief and nothing was felt in the rectum on vaginal examination afterwards. In this case there may have been a gradual oozing of blood, either into the sac or through a small rent, followed by sudden completion of the split during the act of straining. That this is probably the true explanation is suggested by the report of another case of rupture in which the first symptom was the sensation of the pressure of a hard substance obstructing the rectum and causing a desire to defecate.

A QUESTION FOR ANÆSTHETISTS.

BY R. CLEMENT LUCAS, B.S. LOND., F.R.C.S. ENG.,
SURGEON TO GUY'S HOSPITAL.

IT must have occurred in the experience of almost every hospital surgeon that a day or two after an operation of very trivial character, where an anæsthetic has been administered, the patient's temperature has been observed to rise very high, the wound has been examined and found perfectly quiescent, devoid of every indication of inflammation, and completely healed, yet the skin is burning and the patient obviously ill; next a little cough is noticed and soon rusty sputum is coughed up, indicating pneumonia. These cases have occurred too frequently in my experience to be explained either upon the hypothesis of infection prior to admission into the hospital or upon the conjectured basis of chill taken at the operation, where every precaution has been taken to obviate unnecessary exposure. I have noticed it happen on several occasions after operations for hernia, when it might be suggested the patient's resistance might have been lowered by previous vomiting; but I think I may say that I have observed it as frequently after many other operations of more trivial character. The most recent case, at present under my care in Guy's Hospital, is that of a healthy young man admitted for what is now one of the commonest and simplest operations, the aseptic excision of a varicocele. Gas and ether were administered on Feb. 4th and the varicocele was excised, and the wound closed and dressed with aseptic pads. His temperature rose and on the 6th it reached 103° F. His wound was examined and found to be perfectly quiet. On the 7th he began to expectorate rusty, blood-stained sputum, and the expectoration on being examined was found to contain the pneumococcus.

It may, of course, be said that this young man was in the incubation period of pneumonia when admitted, and that he simply developed it in the ordinary course after the operation, but I think these cases, though occurring apparently sporadically, do occur too frequently in hospital practice not to have some other explanation. Gas and ether, it may be urged, are powerful stimulants to the lungs, and sufficient to account for subsequent inflammation. Undoubtedly bronchial conditions frequently follow their administration of sufficient severity in old people to prove fatal. But here is a young, healthy man clearly infected with the infective germ of pneumonia. He was operated on in a well-warmed theatre and placed in a bed on the most protected side of the ward. But apart from this, exposure to cold can no longer be regarded as a sufficient cause of pneumonia. It can only predispose thereto. One might as well argue that cold would cause phthisis without any exposure to the tubercle bacillus.

The question I wish to ask of anæsthetists is whether the apparatus used by them may not sometimes be responsible for germ infection of the lung? I speak of hospital practice, now, where some dozen apparatuses are being constantly employed, carried from patient to patient without any attempt at sterilisation. Considering the enormous advance made of late years in every department of surgery for the better disinfection of everything brought into contact with a wound, it has struck me as somewhat marvellous that so little improvement in this direction has been made by those responsible for the inhalers used for giving anæsthetics. I have often thought it not altogether pleasant to see an anæsthetist blow out and distend the large bag used for ether administration by the breath of his own body, however sweet that may be, and then apply it directly over the patient's mouth. But as matters stand now there is no apparatus used in hospital practice, so far as I am aware, for the administration of either the A.C.E. mixture, or gas, or ether, which is capable of being boiled, or which is otherwise disinfected before being applied over the mouth. If, as I am suggesting (and it may be capable of bacteriological proof), that the apparatus used for giving the anæsthetic, and not the anæsthetic itself, may be responsible for lung infecting inflammations, then some radical change will soon have to be made in the apparatus, which, going from mouth to mouth as at present, seems capable of carrying infection of a kind such as I have indicated.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

RARE CONGENITAL MALFORMATIONS.

BY C. KESSICK BOWES, M.B. OXON.

ON Dec. 30th, 1896, a woman was delivered of a female child at full term after a natural labour, this being her second confinement. Directly the child was born I noticed that the hands presented a very unusual appearance, the fingers pointing upwards towards the elbow, and on examination I found that there was entire absence of both radii and both thumbs. When at rest the outer side of each hand—i.e., the index finger and its metacarpal bone—rested against the forearm, but by manipulation the hands could be brought down at right angles to the forearm, but no further, and there was great resistance to supination. The ulna in each arm was a little curved and seemed shorter than normal, but in all other respects the child seemed to be perfectly developed. On the third day, as soon as the mother's breasts became full of milk, she noticed that as the baby sucked the nipple, after drawing two or three times, the milk returned through the nose, and she had to take her from the breast. I examined the child's mouth and found nothing to account for it, and as this regurgitation continued, and the child began to waste, I suspected some obstruction in the œsophagus. I did not pass a bougie, as the nurse told me that the child had frequent attacks of cyanosis with much choking, and she seemed so fragile and weak that I did not think it would be wise to attempt it. In this way she continued to live, but gradually wasted, and eventually died from exhaustion when thirteen days old.

I obtained permission to make a post-mortem examination and found that the upper part of the œsophagus was simply a cul-de-sac extending about three-quarters of an inch below the larynx, and that the lower part, as it came up from the stomach, opened into the trachea near the point of its bifurcation. The stomach and intestines were quite empty and very thin, just as one would expect to see them in a case of starvation. On opening the heart I found that the interventricular septum was not complete, being deficient in its upper part.

The case is an extremely interesting one, not only on account of the rare malformations, but also on account of the length of time the child lived without any nourishment whatever.

POISONING FROM EATING ROOT OF SCARLET RUNNER BEAN.

BY J. S. MACPHERSON, L.R.C.S., L.R.C.P. EDIN.,
L.F.P.S. GLASG.
MEDICAL OFFICER, UGANDA PROTECTORATE.

THE following account of poisoning from eating the root of scarlet runner bean may be of interest to the profession, as I am not aware of any similar previously recorded case.

On the night of Nov. 18th, 1896, a large number of our garrison, comprising Soudanese soldiers and their wives and Swaheli porters, partook of a small quantity of the root of the scarlet runner bean, which had been collected by our native gardener. Several of the men had the root roasted, while others, probably the majority, simply ate it in the raw state. In a short time—i.e., within a couple of hours—they were all seized with symptoms of poisoning, twisting pain in the stomach and violent vomiting, accompanied by vertigo and prostration. As there was nothing to indicate the precise nature of the poison I had at once recourse to an emetic of thirty grains of zinc sulphate largely diluted with hot water, resulting in prompt emesis with immediate beneficial results. The following morning most of them simply complained of vertigo with an uneasy, twisting stomachic pain, though several suffered more than others from prostration and weak

Hosted by Google

cardiac action. The administration of a purgative dose of sulphate of magnesium with the addition of a few drops of diluted sulphuric acid removed all remaining symptoms, though the vertigo lasted in several cases for from twelve to eighteen hours from the time of eating.

There could be no mistake as to the root in question being that of the scarlet runner bean, as it was planted by ourselves from London seeds and grown in the garden amongst peas, cabbages, and cauliflower, and I cannot conceive unless the root is *per se* poisonous, how it could have absorbed poisonous material from any neighbouring plant. I may mention that the bean itself was largely partaken of by ourselves and we never observed any noxious effect. I forward you a specimen of the root in question, also the plant and bean for analysis. Possibly the deleterious substance may be analogous to that contained in the poisonous variety of cassava or deadly manioc root which is referred to in Mr. Stanley's book "In Darkest Africa."

Ravine Station, Uganda Protectorate.

CHILD IN UTERO CRYING DURING LABOUR.

By E. FITZGERALD FRAZER, L.R.C.S., L.R.C.P. IREL.

I WAS in attendance on a case of twin labour here recently where I applied the forceps to the head of the first coming child. Whilst using gentle traction, and the vertex being still upon the perineum, I was surprised, as was also the nurse, to hear the child cry. At first we thought we were deceived, but in a very short time after the sound was repeated, and before any part of the head was born the same phenomenon occurred several times. Nothing unusual happened during the birth of the second child, which came away naturally. I cannot say whether the pressure of the forceps had anything to do or not with causing the crying. There were no marks of it on the head and the boy is doing well. This instance illustrates the possibility of uterine breathing, as otherwise I cannot see how the vocal cords could have been called into play. I attribute the entry of air into the lungs as having taken place during the time I was putting the forceps into place in doing which no difficulty presented itself. Thinking the particulars may be of interest to the readers of THE LANCET I have pleasure in submitting them.

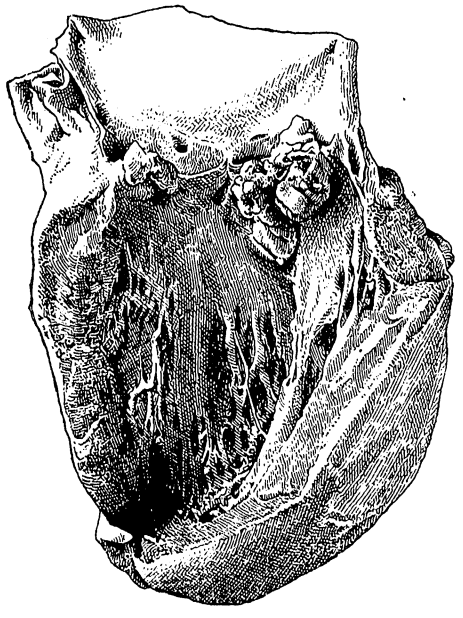
ROYAL UNITED HOSPITAL, BATH.

A CASE OF ULCERATIVE ENDOCARDITIS TREATED BY ANTI-STREPTOCOCCIC SERUM.

(Under the care of Dr. A. E. W. FOX.)



THIS case illustrates one of the more severe types of malignant endocarditis. It is published to show the results of the injection of anti-streptococcic serum, the use of which was decided upon from a perusal of the notes of a successful case which we brought forward in the Mirror of Hospital Practice. The duration of illness before treatment by the serum was about the same in both cases, but the symptoms had been more severe in this patient. The value of the treatment will most probably be found to depend largely on the time the disease has existed before the treatment is commenced. The difficulty consists in making an early diagnosis; but when the diagnosis has been successfully made the method of treatment by the serum has proved of great value in other forms of septicæmia. The publication of cases in which it has been tried, if they illustrate important points, is of much value, although the ultimate result may not be satisfactory. For the notes of this case we are indebted to Dr. W. H. Cooke, resident medical officer.

A man, aged thirty-six years, was admitted to the Royal United Hospital, Bath, on Nov. 17th. He stated that he had not had rheumatism or syphilis; he had been an abstemious man and always lived in England. His illness had commenced seventeen days previously with cold shivers and pains, which commenced in the back. These pains disappeared from the back with the aid of strong turpentine embrocations, but reappeared in the limbs and head. He had had cold shivers daily and became very feverish. There had been no vomiting or diarrhœa. His urine was examined three days before his admission; it smelt strongly of violets. Cold nitric acid produced a cloud, which appeared at the top of the urine first and cleared up on boiling. This was considered as due to turpentine absorption. There was no albumin. On admission to hospital on Nov. 17th he was found to be well-nourished. His complexion was pallid and muddy. The conjunctivæ were slightly jaundiced. The tongue was slightly coated, white, and moist. The temperature was 101·8° F.; the left pulse 100, of good strength; and the respiration 20. There was no distress of any kind, but he complained of some pain in the right arm and right occipital region. There was no rheumatic odour, no œdema of the legs, and no effusion into any joint. The right radial artery was not pulsating and a clot could be felt in the middle third of the brachial artery. It was not tender. The anterior and posterior tibial arteries of both legs were pulsating. The chest was well formed, resonance was good, and the breath-sound normal. As to the heart, relative cardiac dulness commenced at the third left rib and was absolute at the fourth. The apex was in the normal position. At the apex the first sound was reduplicated and the second part of it ended in a slight whiff; the second sound was pure and distinct. At the base, over both the pulmonary and aortic valves, a faint soft systolic murmur was audible. With regard to the spleen, dulness commenced at the upper border of the eighth rib and continued to the lowest border of the ribs; it could not be felt. The liver dulness was increased downwards. The urine was of normal colour, 1020, acid, with no albumin. On the 18th the temperature at 8 P.M. rose to 104·6°. He did not shiver, but sweated profusely. There was no rheumatic odour. On the 19th there was no change in the cardiac signs. On the 20th he had had much pain in the calves during the preceding night. There was no blocking of the anterior or posterior tibial arteries. He was sweating profusely. The bowels were rather constipated. He had been given an injection of 10 c.c. of anti-streptococcic serum on the previous day at 1 P.M. There was no rash or any other discomfort from the injection. On the 21st the pain in the legs had gone. He was sweating profusely. He took nourishment well. The urine was 1020, acid, with a trace of albumin. The systolic murmur at the apex of the heart was becoming more distinct. On the 22nd he had had a better night, but felt rather faint in the morning. He had had some return of the pain in the calves. On the 23rd he had two injections of 10 c.c. each, and similar injections were now made every day. The systolic murmur at the aortic orifice was soft, whereas at the pulmonary orifice it was rough and loud (? two separate murmurs). The pulmonary was louder than the aortic second sound. A loud, rough systolic murmur was heard in the mid-sternal region, probably exocardial. On the 24th he was not so bright in the morning; he had had a bad night. The murmur at the apex of the heart was becoming louder and rougher each day. On the 25th he sweated profusely. There was no pulsation in either of the tibial arteries or the popliteal of the left leg. The leg was only slightly cooler than the right. On the 26th there was no change. On the 27th he felt a little better. The systolic murmur at the base of the heart was now loudest over the aortic orifice, the second sound being short and sharp. The British Institute of Preventive Medicine reported of blood taken from the left arm three days previously: "Streptococci not found either microscopically or by cultivation. No micro-organism has been isolated." On the 28th he felt and looked a trifle better. He had not had a good night. About the lumbar and lower scapular regions much boggy œdema had appeared from the numerous injections in the scapular regions. The left leg and right arm were of the same temperature as the corresponding limbs. On the 29th the injections were left off. On the 30th the temperature, which fell to 100·4°, had risen again

Hosted by Google

to 103·6°. The heart's action was not quite regular. At the aortic orifice the systolic murmur was now very loud and rough, as also at the apex. He now had to be propped up in bed. On Dec. 1st he was worse. He had been delirious during the night. He was drowsy throughout Nov. 30th and was rather deaf in the morning of Dec. 1st. He now had diarrhœa. The injections were continued. On the 2nd he said he felt better, but was evidently worse. At 2 P.M. he was much worse and was cyanosed. The heart's action was irregular and the pulse very small. He had dyspnœa. At 5 P.M. he died. The temperature varied from 98° on the morning of the 19th to 104·6° on the evening of the 18th, but was generally over 103° at night and above 100° in the morning. The influence of the serum was apparently *nil* as regards the temperature record.

Necropsy.—The body was well nourished and muscular. Rigor mortis was present. There was no œdema. The pleuræ contained about a pint of ordinary serous fluid each side. There were a few recent adhesions both sides. The right lung was normal. There was much recent lymph on the surface. With regard to the left lung the whole of the lower lobe was airless and in a state of hypostatic congestion. The pericardium contained from 3 to 4 oz. of clear fluid. There were a few patches of recent lymph. The heart weighed 14 oz.; it was enlarged; there were three patches of recent lymph, the largest being on the right

Left ventricle cut open to show the large mass of vegetations in the aortic valves. (From a photograph.)

ventricle. Both the right auricle and the right ventricle were dilated. The tricuspid orifice admitted four fingers; there was no deposit or ulceration. The left ventricle was hypertrophied and dilated; the mitral orifice admitted three fingers; there was no deposit or ulceration. Almost entirely blocking up the aortic orifice was a vegetation which appeared to arise from the base of the left posterior aortic valve. This vegetation was of the size of a walnut and measured about 1 in. in depth and ¾ in. in breadth; it was covered by recent blood clot. The base of the valve was replaced by vegetation. There were two softened spots in the endocardium immediately beneath the vegetation. This growth extended on to the surface of the anterior valve between which and the right posterior valve there was an irregular calcareous deposit. There was slight atheroma of the aorta. The coronary arteries were not blocked. The spleen was very large, pulpy, and grumous; it was taken out in pieces and weighed about 20 oz. It was so much broken down and disorganised that no infarct could be discovered. The liver was enlarged and weighed 71 oz. It was congested and fatty. The right kidney was moveable and weighed 9½ oz.; the capsule peeled easily; there was a white infarct. The kidney was much congested. The left weighed 6 oz. and he capsule peeled easily; there were several white infarcts; it was much congested. Examination of the head was not allowed. The right brachial artery was dissected out, but unfortunately was lost. The staff of the British Institute of Preventive Medicine very kindly examined a section of the vegetation and found numerous streptococci.

Remarks by Dr. FOX.—The general aspect of grave illness presented by this patient, his rigors, sweats, type of pyrexia, enlarged spleen, cardiac murmurs, and embolic blocking of his right brachial artery pointed conclusively to the diagnosis of ulcerative endocarditis. We therefore determined, encouraged by Dr. Sainsbury's successful case, to try the effects of the anti-streptococcic serum. This treatment was begun as soon as we obtained the serum—on Nov. 20th—when 10 c.c. were injected. In all he had twenty injections, the result being that he certainly looked brighter and said that he felt better. Though the sweats continued the temperature no longer showed such marked fluctuations. The report from the British Institute of Preventive Medicine upon the blood taken from his left arm on Nov. 24th stated: "Streptococci not found microscopically or by cultivation. No micro-organism has been isolated." This was after twelve injections of the serum. Though no streptococci were found in the blood, nevertheless after death streptococci were discovered under the microscope in the vegetations. These streptococci were so embedded in the vegetation that it is difficult to understand how they could have been acted upon by the serum. The fatal termination of the case was no doubt attributable to the almost complete blocking of the aortic orifice by the huge vegetation with its surrounding blood clot. In my own limited experience of ulcerative endocarditis, which began in 1878, when I published my first case in THE LANCET,[1] all treatment has been absolutely futile. I think, therefore, that more help is to be expected from the bacteriologist than from any other direction and I shall certainly give a further trial to the serum treatment.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Ringworm Fungi.—Exhibition of Specimens.

A MEETING of this society was held on Feb. 16th, the President, Mr. BUTLIN, being in the chair.

On the motion of the PRESIDENT a resolution was passed expressing sympathy with the family of the late Mr. G. D. Pollock, a former president of the society.

Dr. COLCOTT FOX and Dr. BLAXALL gave a demonstration of the Plurality of Fungi associated with Ringworm. Microscopical specimens and over forty lantern slides were exhibited. They had examined over 400 cases, clinically and culturally, macro- and microscopically. Their results in the main confirmed the brilliant work of Sabouraud in Paris, but they differed from him in many details and on a few important points. They discussed four groups of fungi—viz., microsporon Audouini, endothrix, ectothrix, and lastly, some rare forms of fungi giving rise to ringworm-like lesions, but yielding faviform cultures. The microsporon caused about 90 per cent. of scalp ringworm in London and was sometimes associated with some macules on the face, neck, &c., but only exceptionally formed circinations. It was almost entirely confined to the human being. The well-known uniform clinical macroscopical appearances were then described. Microscopically they were characterised by a closely adherent external sheath of *small* spores extending some distance beyond the mouth of the follicle and by an infiltration of the hair shaft with mycelium mostly with scanty septa, and ending above the bulb in a striking fringe. The macroscopical appearances of the cultures were demonstrated and shown to be distinctive. The true fructification was then described as obtained by Dr. Fox and Dr. Blaxall from Klatsch specimens of the aerial portion of the cultures. They found the fructification to be on the same plan in microsporon as in endothrix and ectothrix. Chlamydospores were commonly seen in microsporon cultures. The endothrix fungi were so called from the fact that they were confined exclusively to the inside of the fully infected hair. The

[1] THE LANCET, March 2nd, 1878.

Hosted by Google

fungus was strikingly larger than microsporon and occurred almost entirely in chains of mycelial spores. Macroscopically they gave rise to two sets of appearances in the scalp. In one division an appearance superficially resembling a form of alopecia areata was produced (*la tondante peladoide*); in another circinations left patches or little collections of a few stumps. In both divisions the hair tended to break off very short or in the follicle and the stumps were dark and swollen. Circinations on the glabrous skin were somewhat more common than in microsporon. It did not cause beard or nail lesions. It was believed to be exclusively human. The striking cultures aptly termed crateriform by Sabouraud were then demonstrated, and the fructification shown to be practically similar to that of microsporon. The ectothrix fungi were a still less homogeneous group, for they included pyogenic fungi, producing markedly inflammatory and pustular lesions both on the scalp, beard, and glabrous skin. All, at any rate those affecting adults, were believed by Sabouraud to be of animal origin—a view Dr. Fox and Dr. Blaxall were in great measure able to confirm. Microscopically the hairs were enveloped in the intra-follicular portion in a sheath of mycelial spores. Mycelia tended to grow out into the follicular epithelial contents. The hair always, they believed, was liable to be invaded by mycelial threads and was sometimes packed. The fructification was shown to be practically on the same plan as in the preceding groups. Fungi giving rise to faviform cultures, but clinically to ringworm-like lesions, were then considered.

Mr. S. G. SHATTOCK showed the Undescended Testes removed from the inguinal canal of a so-called hermaphrodite who had passed for a female. Histologically there was extreme thickening of the basement membrane of the tubules, together with absence of spermatozoa and spermatoblasts. The groups of granular polyhedral "interstitial cells" normally found in the adult testis, and which bear some resemblance to the cortical cells of the supra-renal, were unusually distinct. Mr. Shattock raised the question whether it was not possible that these cells had some connexion with the "internal secretion" of the organ and might not be responsible for virile characteristics. It had been suggested by Schäfer that the interstitial cells of the pancreas had to do with the internal secretion of that gland. The testicular interstitial cells could not be remnants of the Wolffian body for they were absent in the fœtus and the child. Information was particularly wanted from surgeons as to any differences in the effects of castration in children and adults. In operating for the relief of hypertrophy of the prostate surgeons sometimes removed the entire testis and sometimes the vas deferens only; it was important to know whether there was any different result in the two classes of cases as regards the general effect on the patient, as in the latter class the interstitial cells were left. There was possibly a parallelism between the obesity following castration and that of myxœdema, which was certainly due to loss of an internal secretion.—Mr. STANLEY BOYD said that the results of castration appeared to be very inconstant. He mentioned the case of one man with strong sexual powers on whom double castration was performed for extensive tuberculous disease of the testes. Afterwards he was hardly able to speak without bursting into tears. This passed off after some months, and he married, and said that he was competent sexually. In another older man on whom double castration was performed for tuberculous disease hardly any change was noticed except that he became fatter. Similar interstitial cells were also present in the ovary. It had been shown by Beatson and others that retrogression of mammary cancer often occurred after double oöphorectomy, and he suggested that some morbid secretion of these interstitial cells might have favoured the development of the mammary tumour.

Dr. H. MORLEY FLETCHER showed a Congenital Cyst of the Mediastinum removed from a girl, aged six years, who died from bronchitis and whooping-cough. The cyst lay behind the right bronchus and in fibrous connexion with the œsophagus. The wall was composed of unstriped muscular tissue and lined by ciliated epithelium; it was filled with glairy fluid. It was probably a fœtal outgrowth from the œsophagus and not from the bronchus.—Mr. W. G. SPENCER agreed that it was an œsophageal cyst. In the frog the œsophagus remained ciliated after fœtal life.

Dr. WETHERED showed a specimen of Hypertrophy of the lung from a woman, aged fifty-one years, who had been in the Middlesex Hospital under the care of Sir Richard Douglas Powell. There was no history of any illness until five years before coming under observation, when she had an attack of bronchitis followed by pneumonia. About the middle of November, 1896, a cough developed, accompanied by much dyspnœa. On admission the physical signs were those of bronchitis. At the post-mortem examination the base of the right lung was found firmly adherent to the diaphragm and side of the chest wall and was injured in the process. The upper lobe of the right lung was found to be greatly hypertrophied, being equal in size to about three-quarters of the whole of a normal lung. The edges were rounded and thick; the lung substance was firmer and more resilient than normal, and it was evidently a case of true hypertrophy of lung compensatory to the condition of the lower and middle lobes. In the fresh specimen the lower lobe was bright red in colour, slightly aerated, and a small piece cut off floated in water. The middle and lower lobes together only measured about four inches by three inches. These two lobes were entirely devoid of pigment, thus indicating that the collapse had been of long standing, and if not congenital that it had occurred in very early life. No obstruction in the bronchi could anywhere be found. There was no fluid in the pleural sac and no evidence of external pressure on the bronchus. The left lung was emphysematous and altogether larger than natural, there being an increase of true lung tissue. Dr. Wethered was inclined to think that it was the result of a pneumonia in early childhood, basing the supposition on the size of the lobes, the strong adhesions to the diaphragm and wall of the chest, the absence of any indications of obstruction to the bronchi, and the entire absence of pigment.—Mr. J. H. TARGETT agreed that the condition was due to pneumonia in early life.

Dr. LEE DICKINSON showed a specimen of Extensive Thrombosis of the Pulmonary Artery associated with Congenital Pulmonary Stenosis from a boy four years of age. The stenosis began a little below the valve and there was also a deficiency in the septum ventriculorum. There were firm polypoid vegetations almost occluding the pulmonary orifice and the lumen of the artery was nearly occluded by firm, laminated clot extending into the lungs, which contained many infarcts and broncho-pneumonic patches. Usually in these cases the blood clotted badly and possibly the broncho-pneumonia or sub-acute endocarditis was responsible for the undue coagulability in this case.

CLINICAL SOCIETY OF LONDON.

Gastro-enterostomy.—Sequel to Cases of Excision of Intestinal Growths.—Voracious Hunger and Thirst after Injury or Disease of Brain.—Fatal Cases of Enteric Fever without Intestinal Ulceration.

A MEETING of this society was held on Feb. 12th, Dr. BUZZARD, the President, being in the chair.

Mr. J. ERNEST LANE read the notes of Two Cases of Gastro enterostomy for Carcinoma of the Pylorus. The first case was in a woman, fifty-five years of age, admitted into hospital in November, 1894, with all the symptoms of pyloric obstruction. The stomach was united to the commencement of the jejunum by means of Murphy's button and perfect recovery ensued, the patient being alive and perfectly well at the present date and showing no signs of further progress of the disease. A peculiar feature of the case was that the button was still retained in the intestine. The second case was in a man, forty-two years of age, in a state of extreme emaciation from pyloric cancer. Gastro-enterostomy was performed with Murphy's button and the patient's condition was temporarily greatly improved thereby. At nineteen days from the date of operation he developed symptoms of intestinal obstruction, to which he succumbed. The cause of death was found to be volvulus of the sigmoid flexure, but the stomach and jejunum were firmly united, and there was no leakage at the seat of the anastomosis; the button was still in position. In his remarks Mr. Lane advocated the operation of gastro-enterostomy as a palliative measure in cases where the condition of the patient rendered pylorectomy impracticable, and pointed out that in his first case the malignant disease had remained quiescent for a period of more than two years since the operation.—Mr. L. A. BIDWELL said that he had operated in several

Hosted by Google

cases by Halsted's method, using stitches alone; he preferred simple suture to the use of the button, as it was almost as speedy and less apt to be followed by extravasation.

Mr. WALTER EDMUNDS related the sequel of two previously recorded cases of Excision of Malignant Growth from Large Intestine. The cases were read before the Clinical Society in October, 1893. In the first case a malignant growth in the cæcum was removed by excising the cæcum and establishing an artificial anus. The patient remained in good health for several years, dying from another cause five years and ten months after the operation. There was no recurrence. The large intestine was greatly atrophied and contracted from disease, its diameter being about 1 cm. In the second case, one of excision of a malignant growth in the sigmoid flexure, with re-establishment of the continuity of the bowel, the patient survived the operation three years and three months; the cause of death was probably a recurrence in the lungs.

Mr. STEPHEN PAGET read a paper on cases of Voracious Hunger and Thirst after Injury or Disease of the Brain. He had collected notes of fourteen cases of this kind pointing to the existence of special centres of hunger and thirst close to the centres of speech, probably in the anterior extremity of the temporo-sphenoidal lobe, near the uncinate gyrus. A short account was given of each case, including one in his own practice. The primary injury or disease in each case was as follows: Four of the patients had received a severe blow on the forehead, two had been struck on the side of the head, two had fallen heavily on the back of the head, two had presented signs of a fracture of the base, and one had fallen from a height, coming down in a sitting posture. In addition to these eleven cases of injury there were three cases of disease: one had abscess of the left temporo-sphenoidal lobe, one had a suppurating cyst in the right temporo-sphenoidal lobe, and one had embolism of the left side of the brain. Eight of the fourteen patients suffered from voracious appetite for solid food without much thirst; three suffered both from thirst and hunger; and three had intense thirst without hunger. In none of them was the primary injury or disease fatal; it was, therefore, certain that the centres of hunger and thirst were not situated in the immediate neighbourhood of the vital centres. Three of them had well-marked aphasia; it was, therefore, probable that these centres lay close to the centres of speech, and not improbable that they were connected with the olfactory centre. This hunger and thirst was not the natural appetite of convalescent patients or the result of any general mental derangement, and it was not secondary to traumatic diabetes. With regard to treatment, no harm had come in any case from letting the patient freely indulge his craving for food and drink. The voracious desire lasted, as a rule, for many weeks or months and then came to an end of itself.—Mr. T. SMITH thought that a good case was made out for the existence of a special centre. It could not be a case of exhaustion, as had been suggested, for there was increased activity of function.

Dr. E. W. GOODALL read notes of two cases of Enteric Fever, in which a necropsy showed Absence of the usual Intestinal Lesions. The first case was that of a boy thirteen years of age, admitted into the Eastern Fever Hospital in July, 1894. He died twenty-one days after admission, on the thirty-fourth day of the disease. The chief symptoms were continued pyrexia, a soft and frequent pulse, moderate diarrhœa and abdominal distension, bronchitis, restlessness and delirium, and towards the end muscular tremor, prostration, and coma. Spots were not observed till late in the disease. Post mortem there was slight erosion of the Peyer's patches, which were slate-coloured, but no definite ulceration. The spleen was not enlarged; one parotid gland was suppurating. The second case occurred in 1888, and the account is taken from the hospital records. The patient, a man thirty years of age, died four days after admission on the fifteenth day of his illness. During life there had been numerous rose spots, continuous pyrexia, delirium, and finally coma. At the necropsy the Peyer's patches were much swollen, but not ulcerated. The spleen was enlarged and pulpy. Fagge, Goodhart, Moore, Chantemesse, and Sidney Phillips have related instances of a similar nature.—Dr. SIDNEY PHILLIPS said that on a former occasion he had brought two cases of this description before the society, and had since seen several fatal cases of typhoid fever without intestinal lesions or with only a single very small ulcer.

BRITISH GYNÆCOLOGICAL SOCIETY.

Vote of Condolence on the Death of Sir Spencer Wells.—Exhibition of Specimens and Appliances.—President's Address.

A MEETING of this society was held on Feb. 11th, Mr. MAYO ROBSON, President, being in the chair.

On the motion of Dr. ROBERT BARNES, seconded by Dr. ELDER, a vote of condolence with the family of the late Sir Spencer Wells in their sad bereavement was passed.

Dr. T. BOWREMAN JESSETT showed the following specimens:—(1) A case of Hæmatocele, independent of Gestation; (2) Carcinoma of the body of the Uterus; and (3) Dermoid of the Ovary, with Carcinoma of the Uterus.—Dr. HEYWOOD SMITH thought that the first specimen ought to be further examined with a view to determining whether or not it were due to ectopic gestation. He would ask whether at the necropsy a decidua was found in the uterus.—Dr. PURCELL noted that in the second case no ligature was used, and he could readily understand that there was not much room for such manipulations in a small vagina unless the perineum were split. He saw the operation in the third case; the cyst came down at the same time as the uterus was drawn down; and in this case also clamps were used. He thought that Mr. Jessett could in no way be held responsible for the intestinal obstruction in the first case; certainly there was nothing in the operation at which he was present to determine the fatal result.—Dr. MACNAUGHTON-JONES remarked on the highly ambiguous meaning of the term "pelvic hæmatocele." As commonly used, it was extremely vague and was applied to conditions widely differing in their surgical and anatomical relations. This led to confusion both in diagnosis and treatment. As to the specimen shown by Mr. Jessett he might remark that though ectopic gestation was a frequent cause of pelvic hæmorrhage, the fact that so-called "hæmatocele," due to various causes and in different situations, might occur independently of pregnancy was generally recognised by authorities. Regarding intestinal obstruction after laparotomy he should say there was no more anxious complication nor one more frequently difficult to detect the cause of. The diagnosis between obstruction from septic peritonitis, adhesive peritonitis, appendicitis, ileus, or kink in the bowel, as in Mr. Jessett's case, or strangulation, was difficult, and could only be determined by such symptoms as the mode of onset and time of occurrence, the situation and character of the pain, the shape of the abdomen, and its sensitiveness.—Dr. CLEMENT GODSON said that the second case was a patient from whom he had removed a polypus fourteen or fifteen years ago. She remained well till eighteen months ago and then came complaining of hæmorrhage, but no pain. She thought it was a return of the periods, but the regularity was doubtful, and her age made him suspicious; and when a little later she had an offensive discharge he had little doubt that she had malignant disease. The uterus was slightly enlarged, but mobile. She made a good recovery.—Mr. BOWREMAN JESSETT, in reply, said that no microscopic examination was made in the first case, but there was no decidua in the uterus. He felt sure that the connexion of hæmatocele with ectopic gestation was not nearly so frequent as they had lately been led to suppose. Referring to Dr. Purcell's remarks he thought that the splitting of the perineum should always be avoided if possible.

Dr. MACNAUGHTON-JONES showed a section from an Endotheliomatous Ovary, prepared by Dr. Ludwig Pick, and also a section of a Fallopian Tube which he had seen removed from a patient for Salpingitis, and stained and mounted within twelve minutes after its removal by this pathologist's method.

The PRESIDENT delivered his Inaugural Address.

Dr. C. H. F. ROUTH moved that a hearty vote of thanks be given to the President for his interesting address, and that he allow it to be printed in the journal of the society. He said he had heard many learned discourses, but had not heard one marked by more sterling common sense. He could remember the time when Professors knew less of Gynæcology than the tyro of to-day; but the advances in this branch must not lead them to neglect medicine and surgery; those who had the best knowledge of these branches became the best gynæcologists, whilst their neglect led to extremes in gynæcology, such as not operating at all, or operating too

Hosted by Google

much.—Dr. CLEMENT GODSON seconded the motion, which was carried by acclamation.—The PRESIDENT briefly replied.

Dr. MACNAUGHTON-JONES, by special request, showed some Gynæcological Instruments and Appliances which he had recently seen used in the Frauenkliniks in Berlin, more particularly those necessary for Martin's colpotomy and Landau's vaginal pan-hysterectomy. Having briefly described the steps of these operations he showed the instruments and appliances used in each, including Orthmann's instrument, a combination of uterine sound with claw forceps, which in the former operation was used to steady and draw down the uterus. It was also of great value in other operative procedures on the uterus and adnexa. Landau's operation, in which clamps alone were used, had now been performed some 400 times, with a mortality of little over 2 per cent. He claimed for it that it could be performed in cases in which any other form of hysterectomy would be impossible. Dr. Macnaughton-Jones also showed Landau's combination of branched dilator with trocar and cannula, most convenient for opening pelvic abscesses, and the special needles of Olshausen for ligaturing the uterine and ovarian vessels. Besides other appliances, Dr. Macnaughton-Jones also exhibited an electric lamp with a reflector which could be attached to any electrical connexion, and was specially useful in the Trendelenburg position, being capable of throwing a light of 200-candle power into the basin of the pelvis.

PATHOLOGICAL SOCIETY OF MANCHESTER.

The Bacteriological Diagnosis of Typhoid Fever.—Exhibition of Specimens.

A MEETING of this society was held on Feb. 10th, Dr. T. HARRIS, President, being in the chair.

Professor DELÉPINE demonstrated and explained the chief methods which have been used for the Bacteriological Diagnosis of Typhoid Fever from 1894 (when Gaffky established the relations existing between the bacillus and the fever) till 1895. He showed that, up to that latter date, no single test was sufficient to differentiate clearly the bacillus typhosus from the bacillus coli communis of Escherick and allied bacilli. He then gave it as his opinion, based on a number of personal observations, that though the bacillus of typhoid fever was easily obtained from the organs, and especially the spleen, of typhoid patients after death it was difficult to obtain it during the life of a patient unless one had recourse to puncture of the spleen, which he did not consider a justifiable procedure. Pfeiffer's method (1894) of testing the specificity of a bacillus by observing the changes that took place when the bacillus to be tested was introduced into the peritoneal cavity of a guinea-pig protected by preventive inoculation against the action of the specific bacillus in question (or by injecting into a non-protected animal a mixture of the bacillus and of immunised serum) was a great advance. It gave the means of finding out in a comparatively short time, and by a very delicate test, whether a bacillus was the specific one or not. The modification introduced by Metchnikoff, and specially by Bordet (1895), simplified matters still further, since it did away with inoculation of the living animal and showed that the serum of a highly immunised animal was capable of causing immobilisation, agglomeration, and even degeneration of the corresponding bacillus *in vitro*. Gruber and Durham (1896) showed later that this reaction *in vitro* was nearly specific when used with proper care, and gave very good results. Notwithstanding all these improvements the initial difficulty of isolating the bacillus during the life of the patient remained, and the bacteriological diagnosis of typhoid fever could not be effected in less than two or three days (when it was possible to isolate the bacillus). It was also necessary to have the serum of an animal immunised against typhoid fever ready for use when wanted. Widal, who, from his previous work with Chantemesse (1892) had been led to believe that even at an early stage of the fever the blood of typhoid patients acquired immunising properties, thought that instead of using the serum of an immunised animal for the purpose of testing unknown bacilli it would be much simpler to test the blood of patients with a typical typhoid bacillus to see whether that blood was capable of producing in the bacilli the changes described as occurring *in vivo* by Pfeiffer (1894) or *in vitro* by Charrin and Roger (1889), Metchnikoff (1891), Essaeff (1893), Bordet (1895), Gruber and Durham (1896), when bacilli were exposed to the action of the blood serum of immunised animals. He found that the blood of typhoid patients soon after the beginning of the fever (four or five days) was able to produce on pure culture of the typhoid bacilli immobilisation and agglomeration of these microbes. He found also that the blood of patients not affected with typhoid fever and of healthy persons did not give the reaction. He found also that the reaction took place very rapidly. He felt, therefore, justified in announcing on June 26th last year that the method of serum diagnosis of typhoid fever was a very reliable one. Dr. Grünbaum, who was working in Vienna with Professor Gruber, had, it now appears, been working at the same subject at the same time as Widal; he did not, however, obtain results quite as satisfactory and his theses were not published till September—i.e, about two months after Widal had given very clear and circumstantial accounts of his method. Though for these reasons Dr. Grünbaum cannot claim for himself the credit which is attached to Widal's discovery, it is interesting to know that he had been working on nearly the same lines as Widal and had obtained analogous results. In fact, it is remarkable that so few observers should have thought of this application of previous discoveries. Professor Delépine then gave a brief account of the method which he had followed to avoid a number of accidental fallacies in the application of the test, and he alluded to the work which Dr. Sidebotham and himself had done since the beginning of July, 1896. They had now tested about ninety cases, with results which confirm entirely Widal's original announcement. (A first account of these cases has already been published in THE LANCET of Dec. 5th and 12th, 1896.)

The following card specimens were shown:—

Dr. ASHTON: Gynæcological Specimens.

Mr. BATTLE: Foreign Bodies from the Intestine.

Dr. FOTHERGILL: Microscopical Sections and Drawings of Placental Polypus.

Mr. HENDRIDGE: Composite Odontome.

Dr. LEA: (1) Malignant Adenoma of Uterus; and (2) Parovarian Cyst with Twisted Pedicle.

Dr. M'NAUGHT: Entire Ovum retained in Utero after death of Fœtus.

Mr. J. E. PLATT: Epulis.

Dr. WAHLTUCH: Skiagraphs.

Dr. R. T. WILLIAMSON: Specimens of Blood from cases of Leucocythæmia.

Dr. YONGE: Nasal Polypus.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Prevalence of Cancer.

A MEETING of the above society was held on Feb. 3rd, the President, Mr. GODFREY CARTER, being in the chair.

Dr. ARNOLD EVANS read a paper on the Prevalence of Cancer from a statistical point of view. After remarking that by "cancer" was meant malignant disease in the widest sense, Dr. Evans pointed out that the Registrar-General's report showed that the total number of deaths from cancer in England and Wales during the year 1894 amounted to 21,422, as compared with 11,300 in 1875; that the death-rate per million of the population had risen from 384 in the decennium 1861–70 to 589 in the ten-yearly period 1881–90, and that the increase had been steadily progressive from year to year. He also pointed out that as the local variation in the death-rate from all causes required correction for age and sex constitution of the population, so the same correction should be made in respect of cancer when comparing the mortality-rate in one district with that in another. Dr. Evans mentioned that when this correction had been applied by the Registrar-General to the recorded cancer mortality-rate in the registration counties, some which had a high crude mortality-rate from cancer found places in the list of those with medium or low corrected cancer death-rates. This point was clearly illustrated by means of coloured charts illustrating the area of high, medium, and low cancer mortality-rates in the registration counties of England and Wales. One point which Dr. Evans thought required further investigation was the curious fact that even after correction of age and sex constitution all the most

Hosted by Google

populous parts of the kingdom exhibited a low death-rate from cancer. It was noted that the corrected cancer death-rate for males was subject to greater local variation than that for females. The opinion expressed by the reader of the paper was that the prevalence of cancer was on the increase, but that the increase was not so great as is shown in the Registrar-General's reports, the reasons assigned for this opinion being: (1) that the age constitution of the population is not the same as it was twenty years ago, a relatively larger proportion of people now attaining the age at which cancer is most likely to occur; (2) that greater precision in medical diagnosis has taken many diseases from ill-defined groups and placed them under the heading of malignant disease, this opinion being supported by the fact that the increase in the mortality rate is greater in males than in females; and (3) that inquiries by the General Register Office in reference to vaguely specified diseases add something to the list of deaths from cancer which would otherwise have been differently classified.—Dr. RABAGLIATI took a gloomy view of the advantages of surgical interference in cases of cancer and doubted if life were lengthened thereby. He pointed out that there had been great progress of late years in the treatment of fever and phthisis, but that with regard to cancer the death-rate was on the increase. In discussing the etiology of cancer he laid great stress on the kind of food taken.—Dr. HIME criticised Dr. Rabagliati's views as to the causation of cancer, disagreeing *in toto* with regard to the effects of starchy food.—Dr. J. H. BELL discussed cancer as affecting the eye.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

A Case of Diabetes Insipidus.

A MEETING of this section was held on Jan. 29th, Dr. DUFFEY, President, and subsequently Dr. LITTLE, being in the chair.

Mr. BURGESS related a case of Diabetes Insipidus occurring in a girl fifteen years of age, whose previous history was good up to two years ago, when the symptoms developed after a febrile attack. As well as could be determined thirst preceded the polyuria. The amount of urine passed was sixteen pints per diem; inosite was absent; and the specific gravity was 1·003. The patient had been under observation for eighteen months, during which time the urine was frequently examined. At no time was albumin or sugar present. During the above period there were no characteristic symptoms of either interstitial nephritis or amyloid kidney. The treatment comprised valerian, antipyrin, belladonna, ergot, and nitric acid. Beyond giving temporary relief drugs were found to be worthless. The reason for bringing forward the subject was to elicit the opinions of the Academy whether drug-treatment was of any avail more than causing temporary improvement, and whether the disease had any tendency to shorten life.

The PRESIDENT said that he believed Mr. Burgess's diagnosis of the case he had brought forward to be quite correct. He (the President) had seen only one or two cases of the disease, which seemed generally to follow some debilitating illness. In Mr. Burgess's case he (the President) thought that what was called gastric fever was the more immediate antecedent of the disease. He would ask in what doses did Mr. Burgess give the valerian. Trousseau, who introduced the use of the drug, used to give very large doses of it—as much as fifteen grains of the powdered root per day. A great number of drugs had been recommended for this disease; and, according to some authorities, antipyrin had been given with good effect.

Dr. FALKINER was aware of a case of diabetes insipidus which had lasted for twenty-six years. As far as he understood the pathology of the disease the rational treatment was by ergot.

Dr. PARSONS said he had only seen two cases of this disease. He saw both cases in Vienna; in each an accident preceded the symptoms.

Dr. DOYLE mentioned the case of a man, thirty years of age, who had been in the habit of taking large quantities of drink of all kinds. He suffered from alcoholic paralysis, had hemiplegia, and developed acute mania. He passed immense quantities of urine of a very low specific gravity. Dr. Doyle gave him small doses of phosphorus, with the result that he got quite well and was now in perfect health.

Mr. S. M. THOMPSON mentioned a case of this disease, occurring in a young woman, which he treated with phosphorus. There had been no lesion as a cause of the occurrence of the disease.

Dr. SHAW mentioned a case, which he had attended, of a child, five or six years of age, who was attacked with the disease in question, the symptoms being intense thirst and excessive passing of urine. This went on for two or three years. He treated the disease with opium. The patient eventually developed meningeal irritation and effusion on the brain.

Dr. J. BARTON stated the case of a policeman—a man of large size—who came to him suffering from polyuria. He had been during all his previous life perfectly healthy and had received no injury whatever, but suddenly he began to be very thirsty and to pass immense quantities of urine. His urine, on examination in Trinity College laboratory, was found to be perfectly free from albumin or sugar. The symptoms had been present for two or three months before he saw the man. He first gave him extract of belladonna, which did him no good. He tried a good many other things and finally gave him pulverised opium, and after having taken it for a fortnight the patient got perfectly well and had had no return of the disease.

Dr. PEACOCKE asked if Mr. Burgess had found anything to be effectual in alleviating the thirst. Phosphoric acid and other things had been recommended, but his (Dr. Peacocke's) experience of them was that they were failures.

Dr. JAMES LITTLE related a case which came under his notice a great many years ago of excessive thirst and excessive secretion of urine. Post mortem the bladder was found to be not much distended, but its walls were immensely thickened. There was no sign whatever of cystitis, but the ureters were nearly as large as the small intestine of a child. There was no "surgical kidney." The disease appeared to have been mechanical, having its origin in an enlarged prostate. Not long ago he (Dr. Little) saw what he considered to be a similar case.

Mr. BURGESS, in replying, said that he hoped to have the girl under observation for a considerable time and to be able to give them further information as to the case.

Reviews and Notices of Books.

L'Hygiène Publique de Hongrie. (Public Hygiene in Hungary.) Budapest: E. Boruth. 1896. (A Közegészség ügye Magyarországban.)

WE have before us an interesting monograph covering sixty-five pages, compiled by order of the Minister of the Interior of Hungary, and published in several languages for the occasion of the millennial celebrations at Budapest of last year. The statistics are based upon a Government Report for 1895, showing the condition of public health in Hungary at the close of the first millennium of Hungary's existence as a State.

The kingdom of St. Stephen has an area of 322,310 kilometres or 124,448 square miles, including Croatia; it is therefore somewhat larger than the United Kingdom. Politically, Hungary proper, exclusive of Croatia, is divided into sixty-three countries, varying in size between 1150 and 126,000 kilometres, containing from 50,000 to 717,000 inhabitants, these again are sub-divided into circuits. There are twenty-six cities endowed with self-government; Budapest, the metropolis, contains about 600,000 inhabitants. The superficial area of Hungary proper is 279,759 kilometres. Public sanitation is regulated by a special law enacted in 1876, constituting a central sanitary board or council in the department of the Ministry of the Interior, its executive being the magistrates, assisted by the police. All branches of sanitation are brought before these tribunals, from which there is no

Hosted by Google

appeal, unless the fine exceeds 100 florins or twenty days' imprisonment. Analysts are appointed at convenient distances all over the country; the police have the power to confiscate and to destroy all food and drink declared by the experts to be unwholesome, and to demolish buildings, old or new, if declared by proper authority to be unfit for occupation. The supervision of country medical practitioners, pharmacists, and midwives belongs to this department. Adulteration of food and drinks is severely punished. The following are some of the headings of the law cited above, under which the duties of the authorities are enumerated: (1) security of infant life, supervision of infant asylums, school hygiene, contagious and infectious diseases; (2) prisons and houses of detention; (3) ambulances, help to the wounded; (4) medical practice in general—homœopathy has a chair at the university, but otherwise charlatanism is prohibited; (5) general hospitals and asylums for the insane, both public and private; and (6) railway and ship hygiene. From an international point of view the most important section of that law is doubtless that which treats of epidemics and contagious diseases and the measures to be taken concerning them.

Hungary is the sentinel on the high road of the epidemics proceeding from the East, from Turkey, and from Russia. The supervision of this department is entrusted to special sanitary inspectors of experience. Printed instructions on sanitation are disseminated in thousands of copies among the people, showing what preventive measures are necessary in case of an approaching epidemic. Popular instructions are likewise given as to diphtheria, croup, influenza, cerebro-spinal meningitis, tuberculosis, hydrophobia, syphilis, ophthalmia, typhus fever, &c. Antitoxin (diphtheric) is distributed gratis. In the first year of its application 3737 doses were issued. The decisions of the Dresden Conference have been accepted by the Hungarian Parliament in 1894.

In the Pasteur Institute at Budapest 466 cases were treated in the two years, 1890 and 1891. Many of them came from abroad, where at that time no such establishments were known. In 1892, 144; in 1893, 147; in 1894, 288; and in 1895, 1204 cases were inoculated. The percentage of mortality of the treated was 2·10; but if we exclude cases in which hydrophobia developed during treatment or within twenty-four hours after completing the course of inoculations it amounted only to 1·10.

Purulent ophthalmia was and is still very prevalent in some parts of the country. Special enactments were set on foot, and special measures were taken to prevent its spread in the army, public and private schools, and institutions. A report is submitted by Government and the Parliament on cases of trachoma every year.

Vaccination is compulsory and so is re-vaccination in accordance with the law of 1887. There are public vaccinators appointed and pure lymph is distributed at certain stations. All pharmacies are licensed by Government and must be presided over by graduates of the university. They are considered as parts of public hygiene and not as trade establishments. The Supreme Sanitary Board at Budapest is merely a consultative body and consists of a president appointed by the Crown, a vice-president, and a secretary, besides twelve ordinary members. It gives advice in all matters of public health, recommends candidates for medical appointments, &c.

The percentage of persons suffering from zymotic diseases on the whole population of about 15,000,000 was: in 1893, 7·70; in 1894, 10·2; in 1895, 9·9. The most fatal diseases were: diphtheria, croup, measles, typhoid fever, and scarlet fever. The mortality from small-pox shows the following numbers: there died, of the vaccinated, 37 3; of the non-vaccinated, 62·7. The death-rate was, among the protected, 11·5; among the unprotected, 47·7. This high rate of mortality prevailed before the more stringent sanitary law of 1887 came into operation. Between the years 1879 and 1887 the mortality from small-pox was appalling; there occurred—particularly in the year 1887—15,470 deaths; but since vaccination has been more carefully practised there were, in 1892, 3424; in 1893, 1224; in 1894, 837 fatal cases of variola—a great improvement. But whilst deaths from small-pox are diminishing there is an alarming increase of mortality from tuberculosis; its percentage between the years 1892 and 1895 was progressive, and rose respectively from 9·29, to 10·29, 10·60, and 12·01 of the whole annual mortality.

Puerperal fever is carrying off many more victims than would have been expected in the country of Semmelweis. There is on an average a midwife for every 2043 inhabitants in the country places and one for every 788 in the towns; but there is an unequal distribution of educated midwives, since in 9384 villages, having nearly 6,000,000 inhabitants, there was not a single recognised midwife to be found. The number of beds in hospitals and asylums, both public and private, amounts to over 15,000. There are, besides, permanent emergency hospitals in 2326 towns and communes capable of supplying 13,224 beds in case of an epidemic outbreak and for isolation purposes. Prostitution is under police supervision.

The following was the general mortality per 1000 of the population: in 1890, 32·5; in 1891, 33·4; in 1892, 32·7; in 1893, 30·1; in 1894, 30·2; and in 1895, 29·4—a slow but gradual improvement.

The first real organiser of matters concerning sanitation was the late Dr. Markusovsky, under Minister Trefort. The actual president of the central sanitary board or council is Dr. Chyzer, who has for co-adjutors men of great zeal and superior attainments. Among the juniors we notice the name of Dr. Jenö Farkas, well known in medical circles in London.

Ectopic Pregnancy; its Etiology, Classification, Embryology, Diagnosis, and Treatment. By J. CLARENCE WEBSTER, B.A., M.D., F.R.C.P. Edin., Assistant to the Professor of Midwifery and Diseases of Women and Children in the University of Edinburgh. With eighty illustrations of naked eye and microscopic appearances. Edinburgh and London: Young J. Pentland. 1895.

ALTHOUGH, as the author says in the introduction, the importance of the subject might be considered a sufficient justification for publishing a work embodying the recent advances made in the knowledge of the nature and treatment of this condition, a still more weighty argument is afforded by the plea that he brings forward for consideration a large body of original matter based on several years of clinical and laboratory work. There is an interesting account of the early history of the subject sub-divided as follows: (1) the history of ectopic pregnancy in the period before Dezeimeris; (2) that of the period between Dezeimeris and Lawson Tait; and (3) that of the present time. The first case of ectopic pregnancy of which there is any clear account, is one described by Albucasis, an Arabian physician, living in Spain in the eleventh century. It is not stated here whether the case ended fatally or not, but as in this case parts of the fœtus were discharged through the abdominal wall by suppuration, recovery was not unlikely.

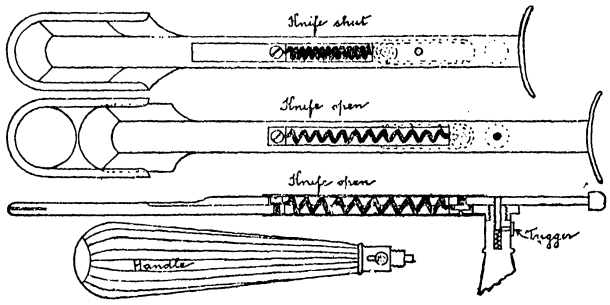
In discussing the changes that take place in the Fallopian tube when pregnancy occurs there Dr. Webster considers it to be fully established that a decidua vera is always formed in the tube. As regards the value of anæsthesia in facilitating the examination necessary for a diagnosis of ectopic gestation the author says: "The danger of post-anæsthetic rupture of the sac from vomiting has been exaggerated by some authors in a most unwarranted

Hosted by Google

manner." It appears to us that the danger in such cases is not due to the occurrence of vomiting. Rupture is much more likely to be caused by the bi-manual examination, unless very cautiously employed.

The anatomical and historical parts of the book strike us as being the most satisfactory; the clinical portion deals with matter that has already received considerable attention at the hands of other authors. There are no less than twenty-two excellent plates at the end of the volume from drawings made by the author. The book must undoubtedly be regarded as a valuable work of reference on ectopic pregnancy.

JOURNALS AND REVIEWS.



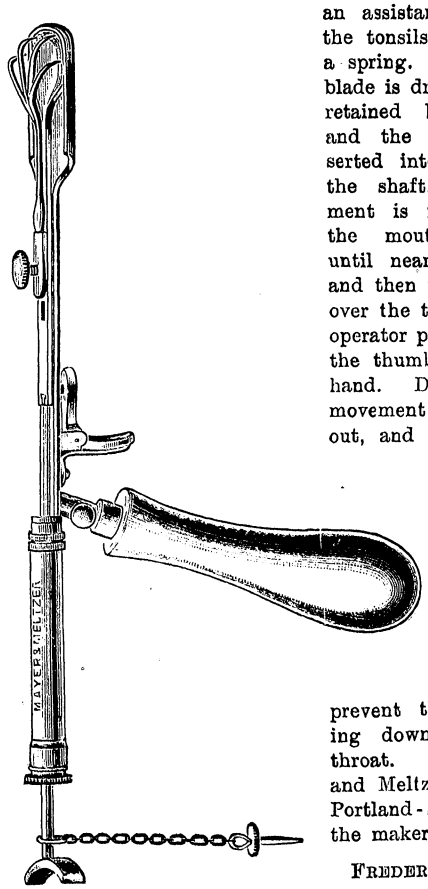
St. Thomas's Hospital Gazette.—St. Thomas's men will notice with regret the announcement in the first number of Vol. VII. of the retirement of Mr. F. G. Parsons, who has so ably edited the *Gazette* from its earliest infancy. Among the articles is a succinctly-written little paper entitled "Notes on the Application of x rays" and the first instalment of a paper by Mr. W. G. Sutcliffe, "Recollections of the Second Matabele War."

Guy's Hospital Gazette.—The recent death of Surgeon-Major Manser, who lost his life at the post of duty, is fresh in the minds of all, and the two letters from Surgeon-Lieutenant-Colonel J. S. Wilkins and Dr. L. F. Childe respectively, announcing the death and appreciating the worth of the late officer will be read with interest. R. O. M. continues his "Notes from a Holiday in Persia." From them we learn that the only hospital in Teheran is under the charge of an American and that in the matter of surgical machinery it is quite up to date—"all the latest from New York."

New Inventions.

AN AUTOMATIC SPRING TONSIL GUILLOTINE.

I WISH to draw the attention of the profession to a form of tonsil guillotine which I have devised to work by "spring action." Owing to the fact that there are numerous forms of guillotine already in use, one naturally hesitates before describing any modification of such an instrument. However, I venture to show the working of one which, with the advice and kind assistance of Mr. C. Vyle, I have had made by Messrs. Arnold and Sons, West Smithfield, and it appears to me to be of some advantage. The accompanying illustrations show at a glance the method I have adopted of applying a "spring" to a Mackenzie instrument. One end of

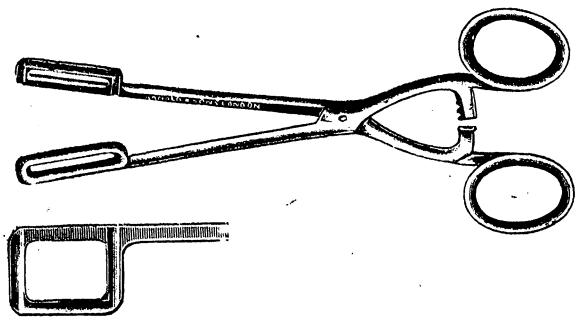


the spring is fitted to the distal part of the lower segment, and is the fixed point, and the other to the knife slide. On setting the instrument in the usual way, by drawing back the proximal end, the spring is thus made tense, and is fixed and kept ready to be instantly released, by a catch within the handle meeting a small hole in the top slide as it is drawn back, and worked by a smaller spring in the handle. When ready to excise the tonsils, the guillotine is released simply by touching a knob or trigger, as seen in the diagram. The spring is covered in and so arranged that it can easily be removed for cleansing purposes, and the strength is sufficiently great to enable the knife, on being released, to instantaneously cut through the tissue. The advantages are: rapidity of action; can be worked with one hand, leaving the other free for the thumb to press externally upon the tonsil, the left for the left and *vice versâ*; the easy and simple mode of working; the instrument cannot get out of order; is simple in its mechanism and seems to answer the purpose for which it is intended — namely, immediate excision when once the guillotine is favourably *in situ*, and being thus steady and not requiring any force from the operator, so preventing any movement or displacement from the tonsil otherwise necessarily induced.

London. R. BROOKS POPHAM.

AN IMPROVED TONSILLOTOME.

THIS instrument does away with the necessity of an assistant to push up the tonsils. It works by a spring. Before use the blade is drawn back until retained by the catch, and the small pin inserted into the hole in the shaft. The instrument is introduced into the mouth horizontally until nearly in position, and then turned sideways over the tonsil, while the operator pushes it up with the thumb of the other hand. During the last movement the pin falls out, and on pulling the trigger the tonsil is removed instantaneously, painlessly, and with great precision. A specially devised guard is added to prevent the tonsil falling down the patient's throat. Messrs. Mayer and Meltzer of 71, Great Portland-street, W., are the makers.



FREDERICK SPICER, M.D. Durh.
Devonshire-street, Portland-place, W.

A NEW TONSIL FORCEPS.

SOME time ago, having to excise a number of enlarged tonsils, I found great inconvenience in working with the instruments commonly used for that purpose. Accordingly, I designed the instrument illustrated below, which has been most satisfactorily made by Messrs. Arnold and Sons, London. The mode of using the instrument is as follows. The forceps having been introduced into the mouth and counter-pressure made beneath the angle of the jaw, the enlarged tonsil is thereby placed between the blades of the forceps. The handles then being approximated, the instrument is locked by means of the neck and catch with which it is furnished. The tonsil is then drawn well towards the middle line by means of the instrument. A tonsil bistoury is then passed from below upwards behind the tonsil about to be removed. The bistoury is made to cut from behind forwards, being kept closely applied and parallel to the sides

Hosted by Google

of the grasping portion of the forceps. For those who would wish to make "assurance doubly sure" the bistoury can be inserted within the fenestræ and made to remove that portion of the tonsil contained within the blades, which, inasmuch as the fenestræ are fairly large, practically means the entire gland. The latter mode of operating will be

facilitated by studying the portion of the tonsil enclosed between the blades by inserting a small tumour-hook in it. This method of removal cannot be effected without some detriment to the edge of the bistoury. The advantages claimed for this instrument are as follows: (1) impossibility of wounding the internal carotid artery, as the blades of the forceps clasp the gland in a plane at right angles to the line of the artery; (2) extreme ease of application, as both blades are in full view of the operator; (3) when applied is retained in position by catch, thus enabling the operator to dispense with assistance; (4) can be applied to either side with equal facility; and (5) the grooves on the blades of the forceps obviate any tendency on the part of the tonsil to slip from the grasp of the instrument.

Littleborough. G. KIRKMAN FINLAY, M.B., B.Ch., B.A.O.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on Feb. 11th, the President, Sir WILLIAM MAC CORMAC, being in the chair.

The secretary reported the death, on Jan. 31st, 1897, of Sir Thomas Spencer Wells, Bart., past President and past member of the Council of the College.

The Council passed a resolution of condolence.

The report from the committee on the circular to the Fellows was received and adopted. It showed that 1150 circulars were sent out and 686 valid answers were received. Of these answers 485 negatived the proposal to give direct representation upon the Council to Members of the College. Of the minority of 201, who thought that the Members should be admitted to the privilege, 42 thought the representation should be by Members only, 40 by Fellows only, and 119 were indifferent. Only 67 thought that Members should be qualified to vote irrespectively of their standing in the profession, 125 voting for some age restriction and 9 not replying to the question; 129 considered that new seats should be added to the Council, 49 that seats should be taken from the Fellows and given to the Members' representatives, and 23 ignored the point.

A report was presented from the delegates of the two Royal Colleges on the question of a Teaching University for London and the following resolution recommended by them was adopted:—

"That the Royal College of Physicians of London and the Royal College of Surgeons of England, in full accord with their previous action, express the earnest desire that Her Majesty's Government will at the earliest opportunity re-introduce a Bill for the reconstitution of the London University by Statutory Commission on the general lines of the report of the Cowper Commission, and do assure the Government that such a course will have their approval and support."

Mr. W. Rivington resigned his position as one of the delegates.

A letter was read from Dr. Michael Beverley stating that at a largely-attended meeting of the profession resident in Norwich and at a very numerously attended meeting of the Norfolk and Norwich Medico-Chirurgical Society, Sir Frederic Bateman and he were appointed a deputation to present a Memorial to the College asking for advice with regard to professional relations with medical aid associations.

A committee was appointed to receive the deputation and to report on the whole matter to the Council.

A letter was read from Lord Lister thanking the Council and the Fellows for their congratulations.

The Council approved, as proposed by the Royal College of Physicians of London, the inclusion of bacteriology as a subject of study and examination under the regulations of the combined Examining Board, and the addition for this purpose of the words "and in bacteriology" to Section 1, Sub-section 5, par *d* of the regulations.

It was moved by Mr. Macnamara and carried *nem. con.*—

That the Council do hereby withdraw their representatives from the Civil Rights Defence Committee acting on behalf of Mr. R. B. Anderson, F.R.C.S. Eng.

It was moved by Mr. Heath and carried—

That the resolution of the Council of Dec. 21st, 1893, relating to the appointment of Representatives of this College on the Conjoint Finance Committee be rescinded and that the treasurers of the College be *ex-officio* Members of such Committee.

CONGRATULATIONS TO LORD LISTER.

WE have received the following letters for publication from the President of the Royal College of Surgeons of Edinburgh:—

Royal College of Surgeons of Edinburgh,
3rd February, 1897.

DEAR LORD LISTER,—I have the pleasure of transmitting to you the congratulations of the Fellows of the College on the occasion of the further honour conferred on you by the Crown in your elevation to the Peerage, passed with acclamation at the meeting of the College to-day.

I am, Dear Lord Lister, yours very sincerely,
JOHN STRUTHERS.

TO LORD LISTER,—We, the Fellows of the Royal College of Surgeons of Edinburgh, met to-day for the first time since Her Majesty conferred on you the honour of elevation to the Peerage, embrace the opportunity of offering you our congratulations on an honour so well deserved and which is enhanced by the fact that it is the first occasion on which that honour has been conferred on a member of the medical profession.

It is with pleasure that we, some of us your former colleagues, many of us your former students, recall that you became a Fellow of the College in 1855, that your career as a Teacher, and those Researches that were to bear so much fruit, began in Edinburgh; and, after being continued for some time in Glasgow University, were resumed in Edinburgh, where, in the position of Professor of Clinical Surgery, you inculcated the principles of Antiseptic Surgery to large classes of students and illustrated these principles by your practice in the Royal Infirmary.

While the results of your labours are appreciated by all of us, it is only those of us who recollect what Surgery was before you enforced these principles who can fully realise the improvements that have been effected by their application. What were dangerous operations are now done with comparative safety, operations that could not be attempted are now undertaken with success, and wounds of all kinds now heal rapidly and cleanly. Further, we recognise that the benefits of the application of antiseptic principles extend beyond surgery; that the mortality in Maternity Hospitals has thus been very greatly reduced, and that antiseptics are employed with advantage in many departments of the Practice of Medicine, including that of the regulations for Public Health. We need hardly add that these principles are fully applied in our Royal Infirmary and other Hospitals here, and everywhere in Edinburgh.

It is a source of pleasure to us to think that the new era in surgery which you have established will render your name imperishable as one of the benefactors of the human race. All of us, former colleagues and pupils alike, join in further expressing our esteem for you personally, and in wishing you yet many years during which you may enjoy the satisfaction of knowing that your great work is appreciated throughout the world and during which you may still more exert your influence.

In name and by authority of the College,
JOHN STRUTHERS, President.

[REPLY]

12, Park-crescent, Portland-place,
6th Feb., 1897.

MY DEAR PRESIDENT,—I beg you to express to the Fellows my warmest thanks for their generous words of congratulation transmitted by you. They carry me back to the days when I began to teach Surgery with the sanction of the College, entailing, as it did, that of the University; a most liberal arrangement, then, I believe, unique in the British Island, one which has certainly contributed largely to the greatness of the Edinburgh school, and to which I am personally incalculably indebted.

I need hardly say that this expression of kind feeling on the part of my former colleagues and students has given me the greatest pleasure.

Believe me, very sincerely yours,
JOSEPH LISTER.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 20, 1897.

THE House of Commons last week, when it went into Committee of Supply to resume the debate on the army estimates, was the scene of an interesting and lively discussion which was followed by an unexpected result. It was generally believed that the Government proposals were unsatisfactory to many of their own followers and would meet with strong opposition, especially on the part of the military members and the advocates of radical reforms in the Army and War Office. The debate was one of the few occasions, however, in which a speech told with considerable effect on the House, and, to adopt a frequently-applied phrase, took the wind out of the sails of the Opposition. Mr. BRODRICK defended the Government measures in a speech of singular clearness and ability. It does not, of course, fall within our province to pronounce any opinion upon the wisdom, efficiency, or otherwise of measures of military policy and army organisation in so far as they do not affect the health of the soldier or the medical service, but we may, nevertheless, say that he showed that the Government had, at any rate, considered the situation in all its bearings and had adopted what, under the circumstances, seemed to be the most prudent and practicable course. But what was more to the point, Mr. BRODRICK showed that they had, in what they were doing, the approval of the late, and of the present, Commander-in-Chief. This had the effect of disarming the military members of the House and of depriving the criticism of Sir HENRY CAMPBELL-BANNERMAN of any effective sting.

The part of Mr. BRODRICK'S speech which more directly concerns us, however, was that in which he had to deal, as he said, with the "thorny subject" of the condition of the Army Medical Department. He admitted that for some time past there had been difficulty in procuring sufficient candidates. Many reasons had been adduced for this, among the principal of which, he said, were the questions of rank and social position, of the examinations having been conducted under less favourable circumstances for candidates from Irish and Scotch medical schools, of the rate of pay in India, and of the prolonged foreign service. Lord LANSDOWNE had given, Mr. BRODRICK declared, the most careful personal attention to all these questions, had received various deputations, and had spared no pains to get to the root of the difficulty. Lord LANSDOWNE was, moreover, very anxious that every consideration should be shown to the officers of a most valuable and distinguished department. As regards the constitution of the examining board for the army, we have Mr. BRODRICK'S assurance that, while every consideration would be given to eminent members of the Scotch and Irish schools for filling vacancies on the examining board, the board would be constituted solely with reference to the professional eminence of its members, without regard to the mere fact of their coming from one part or another of the United Kingdom. We confess that we have never considered this was a matter that had much, if anything, to do with the popularity or otherwise of the medical service, or that candidates were deterred from presenting themselves for examination on this ground; and the fact that the falling off of Irish candidates is no greater than the falling off of other candidates deprives it, as Mr. BRODRICK rightly alleged, of any special significance or importance. Mr. BRODRICK then briefly passed in review the history of the department in connexion with the question of the titles of medical officers and that lack of social consideration with which it was closely bound up. He traced the origin of this to the abolition of the regimental system and the consequent loss of that special and close personal contact and intimate relationship that existed between medical officers and their regimental brother officers. There is, no doubt, a good deal of force and truth in this view; but we would remark that the regimental system was abandoned in the interest of the State, and it should be remembered that there was even then a good deal of discontent expressed by many regimental medical officers at their position at mess, considering their relative rank and the amount of their contributions to the mess and band fund. What is now apt to be forgotten, however, must be admitted by everybody, and it is this: that since the introduction of the present system the gain in regard to medical and field hospital organisation, field hygiene, and medical arrangements generally has been enormous. The splendid results, as far as the sick and wounded are concerned, that have been obtained in many of our late campaigns under the present consolidated system could not have been accomplished under the older regimental one. But all this is now ancient history; we have to address ourselves to the state of things as they exist at the present time. We are glad to recognise that Lord LANSDOWNE has done his best to remove several real and substantial grievances of which, as we have always contended, medical officers had to complain. He has, we are told, after communication with the India Office, secured to them an increase of pay in India and the Indian tour has been moved back to five years instead of six. By the increase of pay we trust we are right in assuming that the medical officer will get the pay of his army rank whilst serving in that country. Assistance is also promised towards forming medical messes at large stations and in providing the necessary accommodation for them where possible; and opportunities to study on return from foreign service will likewise be afforded. We are not told, however, whether the period of home service will be increased and that of foreign service consequently decreased—a very important consideration; nor are we told whether medical officers will be moved about when at home less than they are at present.

But it is when we come towards the end of Mr. BRODRICK'S remarks on the Medical Department that the real difficulty has to be encountered. It is many years since we first suggested that the medical service should be made into a Royal Corps and placed on a footing analogous to that of the other scientific corps of the army. The medical service is a departmental one, and

Hosted by Google

its officers have at present composite medical and military titles carrying substantive rank in all that appertains to their own service and duties. These concessions, Mr. BRODRICK says, made in deference to the recommendations of the late Sir ANDREW CLARK, though welcomed at the time by the profession, have not altogether acted as was desired. Some of the composite titles, we would parenthetically remark, were very unhappily chosen. What medical officers ask for is that they should be formed into a corps and welded with the Army Hospital Corps under some such title as the Royal Medical Staff Corps or the Royal Corps of Surgeons, of which they should be the officers with corresponding military, and not composite, titles. They will consequently be disappointed to learn that none of the proposals which have been submitted to the Secretary of State for giving new forms of army rank to the medical staff appear to him desirable for adoption. He does not believe that by such titles the Medical Department will obtain the status to which their talents and professional acquirements entitle them, and says that anxious though the War Office is to meet the medical profession on all points this is not one of those on which further action appears to be desirable.

THE adverse conditions under which the poll of the Fellows of the Royal College of Surgeons of England on the question of the direct representation of the Members of the College on the Council was taken have produced their natural result. By 485 votes to 201, a majority of 284—considerably more than two to one—the Fellows of the College have reversed the decision arrived at by the half-yearly meeting of the Fellows in January, 1896, and have decided that "it is not desirable to give the Members of the College direct representation upon the Council." In the face of this vote the analysis of the 201 affirmative answers which forms part of the report of "the Committee on the Circular to the Fellows," and shows how those favourable to the representation of the Members would carry their views into effect, loses much of its intrinsic interest. Nevertheless, there are some noteworthy points in this analysis. The first point is that out of the 201 affirmative voters no less than 161 would admit Members of the College to seats on the Council, and 42 of these are in favour of the representation of Members being by Members only. Only 40, therefore, of the 201 affirmative voters were in favour of the representation of Members being by Fellows only, and 119 were for the representation being by Fellows and Members indifferently. This shows a remarkable growth of liberality of opinion among the liberal-minded Fellows. On the other hand, among the 201 affirmative voters there is a stong preponderence of opinion in favour of limiting the concession of the franchise to Members of a certain standing, 67 voting that Members of the College should be qualified to vote without restriction as to standing and 125 imposing a limit of years. As to the seats to be assigned for the representation of the Members, the committee states that the numbers mentioned were too varied for convenient classification, ranging from two to half the Council, 129 being in favour of obtaining the seats by addition and 49 by subtraction. The chief reason for the preference given by the 49 voters to obtaining the seats by subtraction was no doubt the belief that a Council of 24 is quite large enough.

We are neither surprised nor discouraged by the result of the poll. We are not surprised because we carefully pointed out at the time that the circular of the Council was issued that the conditions under which it had gone out would injuriously affect the prospects of a successful issue for the Members of the College. We may remind our readers that the adverse conditions were these: In the first place the subject of the representation of the Members of the College on the Council had been discussed by the Council, and the Council, by 11 votes to 8, passed a resolution to the effect that as the Council represented the Members of the College as well as the Fellows no further representation of the Members was desirable. When this vote was taken the minority was weakened by the absence of two or three members of the Council favourable to the concession. In the second place, the circular itself was so drawn as to show a decided leaning to the negative side. This was chiefly due to the action of the Society of Members of the College in urging upon the Council to incorporate in the circular the reasons of the society for asking for representation, such reasons being by no means the strongest or least assailable reasons that could have been formulated. The request destroyed the prospect of securing the issue of a circular of a neutral tint, as the committee on the circular to the Fellows doubtless considered themselves bound to answer and to correct the statements of the Society of Members. The third and, we think, the most potent adverse influence was the issue, at the precise moment when the circular of the Council was being sent to the Fellows, of another circular from the Society of Fellows of Manchester, accompanied by a reprint of an article or letter which a member of the Council of the College had published in the medical journals some weeks previously, expressing views strongly antagonistic to the claims of the Members of the College.

Nothing is more encouraging to us than the fact that in spite of the adverse influences on which we have commented the opponents of the concession fall short by nearly 100 votes of a majority of the Fellows. This circumstance is of the greatest importance to the cause of progress, for the material is already at hand by which a minority on the present poll can be converted into a majority at the next. For the time the result stops progress both for the Fellows and the Members of the College and prevents the Fellows securing a new Charter to make statutory the half-yearly meetings of the Fellows of the College. But it cannot stop the progress of opinion among Councillors, the Fellows and the Members of the College, and the profession generally. It cannot prevent the gradual disappearance of the majority of 284 until the requisite affirmatory majority is obtained. The growth of liberal opinion in the profession may be slow, but it is sure, and will not be hindered by the fact that exclusive privilege dies hard.

IN the dental profession at the present time there seems to be quite an epidemic of prosecutions, the majority of which are in connexion with Clause 3 of the Dentists Act—namely, the one dealing with unregistered persons. At

Hosted by Google

Brighton no less than seven such summonses have been heard within the last few weeks, while at Swansea there have been five similar cases. The Dentists Act, as amended by the Medical Act of 1886, allows private individuals to carry out prosecutions, but those who undertake such work should make certain of their facts beforehand and not leave any stone unturned to ensure success, as a single failure is a heavy discount on many successes. That this care is not always taken is well shown by two prosecutions during 1896, in one the action being lost by the technical error of not putting in the Dentists' Register as evidence, while in the other the person prosecuted was actually on the Dentists' Register.

With regard to the actions at Brighton we find that in the three heard on Jan. 19th one was adjourned and two were unsuccessful. In the first of these it was admitted that the name of the defendant did not appear upon the Dentists' Register, and the defence was that although such was the case the defendant had practised dentistry for twenty-two years and was therefore in practice before the passing of the Act. After hearing the evidence the stipendiary adjourned the case for eight weeks on the ground that an action is to come before the High Court in which a number of dentists, including the defendant, are proceeding against the General Medical Council for refusing to place their names on the Dentists' Register under Clause 37 of the Dentists Act. This case is one of the greatest importance, and its result must have an important bearing upon the judicial position of the General Medical Council in the administration of the Medical and Dental Acts. In the second case the person who appeared to answer the summons was not the same seen by the witnesses for the prosecution, and as the solicitor for the plaintiff did not press the case the summons was dismissed with costs. The third case was against a Dr. DINJIAN, manager of the American Dental Institute, who was admittedly not registered. The stipendiary dismissed the case on the ground that sufficient evidence had not been produced to prove that defendant held himself out as a qualified dentist. This idea is somewhat difficult to fall in with when the defendant admits to being the manager of the Brighton branch of the American Dental Institute. The four cases heard on Jan. 26th, in addition to one heard at Hove, were all successful. Of the cases at Swansea the summonses have been dismissed in two, while in the remaining three no judgment has so far been given.

In another case which has recently been before the courts the interest centred on the question of damages for malpraxis. The plaintiff, to state the case briefly, sued the American Dental Institute on the ground of alleged negligence on the part of one of their operators in attending to him. The plaintiff had, as far as can be gathered from the newspaper report, a bridge made; for this he paid sixty guineas. He subsequently suffered much pain and discomfort, due to the roots to which the bridge was fastened being left untreated and in a septic condition. The plaintiff was eventually seen by a Dr. BOSWELL, who seems to have given him relief. Evidence in favour of the plaintiff was given by some prominent dental surgeons, and he was at the conclusion of the hearing awarded £150 damages. As far as the question of malpraxis goes the case was of undoubted interest, and although we are unable to discuss now the whole question in detail it is well to point out that the name of M'CORMICK does not appear in the Dentists' Register for 1896. This fact should not, we think, be lost sight of by the proper authorities. The action is a glaring example of the insufficient way in which the public are protected from the hands of unqualified persons.

THE question of the registration of midwives bids fair to become as hardy an annual as that affecting the deceased wife's sister. A new Bill has been introduced and backed by twelve Members of the House of Commons, which Bill was down for second reading upon Feb. 12th, although it never arrived at that stage of progress. Of this Bill, which is shorter and less complex than that introduced by Lord BALFOUR of Burleigh in the House of Lords in 1895, we print the full text in another column, so that our readers can study its provisions at leisure for themselves. In some ways it is an improvement upon its predecessor; for instance, Lord BALFOUR'S Bill defined "midwife" as a woman who undertakes to attend cases of natural labour without the direct supervision of a medical practitioner. The Bill now before the House wisely avoids this pitfall by defining "midwife" as a woman who undertakes to attend cases of labour in accordance with the regulations to be laid down under this Act. Thus it avoids defining the impossible by omitting the words "natural labour" and shifts the responsibility to the shoulders of the hereinafter to be constituted Midwives Board (*vide* Clause 5). The local supervising authority is by both Bills practically the same—namely, the local sanitary authority; but Lord BALFOUR'S Bill provided for payment for this supervisory duty, whereas the present Bill makes no such arrangement, unless Clause 6 may be taken to include a provision of this kind.

We think it most unlikely in the present state of public business that this Bill will ever reach its second reading, and we understand that Sir WALTER FOSTER intends to move its rejection; but nevertheless it is of importance that the profession should grasp the main facts of the Bill, so as to have rational grounds either for opposing or furthering the measure. It is, we believe, universally allowed that the present system, whereby any woman, however ignorant, may attend women in childbed without let or hindrance, without there being any check on her spreading puerperal fever, and without being under any kind of authority, is intolerable and should be altered; but when it comes to laying down the details of a measure whereby the present state of matters may be improved the difficulties in the way begin to appear. We must remember that midwives always have existed and always will exist; that women, especially among the poorer classes of the community, will continue to prefer to be attended by a midwife in preference to a medical man, possibly on account of cheapness, but in many cases, we expect, because the midwife does not lay down so many (to their minds) unnecessary and harassing rules for their guidance during convalescence; that this partiality, though it may appear to well-regulated minds very foolish, is a factor which must

Hosted by Google

be reckoned with in dealing with this question; and that unless the Legislature is prepared to absolutely prohibit all and every kind of unqualified practice midwives will continue to be an integral part of the social community. At present the midwife is a sort of free-lance, but as a result of all the registration Bills hitherto brought in she would come to be recognised, despite all said to the contrary, as a duly licensed medical practitioner.

Although we yield to no one in our desire that puerperal women should be protected from the dangers of sepsis brought about by the ignorance or carelessness of their attendants, yet we cannot agree to any scheme which does not lay down a hard-and-fast line between a midwife and a medical practitioner. The present Bill in Clause 5 lays all the responsibility of defining the duties of midwives upon the Midwives Board. Paragraph *f* of Section 2 of this clause is as follows: "To frame for approval by the General Medical Council rules for regulating, supervising, and restricting within due limits the practice of midwives." We must confess ourselves unable to see how the General Medical Council or any other body is to frame rules which shall lay down for the guidance of a midwife when her own attendance shall cease and it becomes necessary for her to call in a medical man, for we take it that this is meant by the paragraph under consideration. If the Bill ever reaches the committee stage we consider it absolutely necessary that some clause should be added making it clear as to what in the opinion of the framers of the Bill a midwive may or may not do; for as it stands the measure is very incomplete, and too much seems to be left to those who are to arrange the details. All the same it is an honest and carefully-drawn plan to attempt to meet a humanitarian want, and if the points which we have endeavoured to indicate are dealt with we think that, as a part of the law of the land, it would in some ways diminish pain and suffering. At any rate, to quote the great master HIPPOCRATES, if it do no good it will at least do no harm, always provided that it is made perfectly clear not only to those who can read the Bill, but also to that class from which the midwife's patients come, that even when registered the midwife will be in no way a "doctor," but only a nurse. We should like to add that we see no reason why this question should not be discussed in the profession calmly and with politeness. The points are all perfectly clear, and the procedure requires formulating, but there is no necessity for ill-tempered recrimination.

PORTSMOUTH AND GOSPORT.—The total funds contributed towards the restoration of the Royal Portsmouth Hospital as the memorial of Her Majesty's long reign had reached on Feb. 13th £5139. At a meeting at Gosport last week it was decided to establish a Victoria Nursing Institute. An amendment was moved by a working man that 100 workmen's dwellings should be provided instead. Perhaps it is a pity that this was negatived, for workmen's dwellings are greatly needed. Parts of the town much need attention, and long ago the urban council were asked to provide better dwellings for the poorer classes. They, however, decided on Feb. 18th to take no action under the operative section of the Housing of the Working Classes Act, relying on private enterprise and the plea of costliness.

Annotations.

"Ne quid nimis."

THE WATER-SUPPLY OF THE METROPOLIS.

WE begin to-day the report of a Commission which we have instituted to inquire into the water-supply of the metropolis—a subject which bids fair to assume a political importance proportional, if possible, to its importance when viewed from the aspect of public health.

THE FIGURES OF VACCINATION.

AT a meeting of the Royal Statistical Society held on the 16th inst. at the Royal United Service Institution a paper on "English Vaccination and Small-pox Statistics, with special reference to the Report of the Royal Commission and to recent Small-pox Epidemics," by Mr. Noel A. Humphreys, was read. He arrived at the following conclusions (among others) based upon the figures discussed: 1. That the mean annual death-rate from small-pox at all ages in England and Wales, which was 408 per 1,000,000 in the twelve years for which records exist prior to compulsory vaccination, fell to 126 per 1,000,000 in the forty-two years since vaccination was made compulsory, which period included the world-wide epidemic of 1871-72. 2. That the main part of this decline of mortality occurred among children under the age of ten years, who may be presumed to have been principally affected by the increase of infant vaccination. 3. That the age-incidence of fatal small-pox had entirely changed under the influence of increased infant vaccination; and that small-pox, from being mainly a disease of childhood, was now proportionately more fatal to adults. 4. That, judged by the statistics of the last six principal local small-pox epidemics, the proportion of deaths of children bore a constant ratio to the proportion of children officially returned "unaccounted for" as regards successful vaccination. 5. That efficient infant vaccination conferred a practically complete immunity from fatal small-pox during the first ten years of life. 6. That the increase in the proportion of adult deaths from small-pox must be attributed to the waning of the protective effect of infant mortality, this hypothesis being corroborated by the steady increase in the proportional case-mortality of vaccinated persons in recent epidemics at successive age-periods above ten years. 7. That both the small-pox attack-rate and the case-mortality was far lower at all ages among those who had been vaccinated in infancy than among the unvaccinated. 8. That the type of disease suffered by small-pox patients was far more severe among the unvaccinated than among the vaccinated; and that the severity of the type appeared to vary with the number and quality of the vaccination marks. 9. That, judged by the statistics of small-pox hospital nurses and attendants, successful re-vaccination afforded practically complete protection to adults, even to those brought into actual personal contact with the worst forms of disease. We recommend these conclusions to the careful consideration of those who have been unable to read aright the lessons taught by figures.

THE "LOCAL PRACTITIONER": A PRESS PARODY.

IT is a most satisfactory sign of the spirit of our times that the interests of hospitals, which have done and are doing so much for the public good and for the reputation of medicine, are well befriended by the daily press. We

Hosted by Google

regret to temper this admission with any qualification, but the unfortunate proneness of zeal to consort with ignorance and to proclaim this failing in the press as elsewhere leaves us no alternative. A writer in one of the local newspapers of the metropolis has recently interested himself in the problem of hospital finance, especially with that part of it which concerns the Great Northern Central Hospital. Naturally and rightly, he commends the practice of that hospital. He can hardly say too much in praise of the practitioners who have there worthily done their duty (though not alone in that glory). Here his own financial operations break down, for having thus well paid the Æsculapian Peter he proceeds to rob the unmitred Paul who administers physic *in partibus extra muris*. He would cast no slur, he tells us, upon "local" practitioners as a body—a somewhat confusing description, which we may freely translate as equivalent to what we call general practitioners—but the professional services of many such are, he says, worse than useless. He then draws an imaginative picture of medical men who were qualified twenty years ago, then went to sleep, and learnt their craft no more. Some of them, he says, should not be allowed to attend a sick dog. He solemnly warns the public that they cannot learn these truths too soon. We would, on our part, rather caution them not to accept them too readily from this authority. As everyone knows, there are degrees of excellence or the reverse in every calling—medicine and even journalism not excepted. Nevertheless, a criticism so ill-informed and so sweeping as that to which we have referred, though ostensibly favourable to one section of the medical profession, can only be regarded as gratuitously insolent towards another not less deserving, and we trust it will be so received by the public to whom it was addressed in what was, perhaps, a moment of aberration.

"WALLACE-ISM!"

WE have received a publication called the *Herald of Health*, edited by C. Leigh Hunt Wallace, and "having for its object the physical regeneration of man." Other objects are, we gather from a study of its pages, vegetarianism, anti-vaccination, the puffing and vending of a non-poisonous preparation of aconite, and generally to further the interests and tenets of a sect called "Wallace-ites." We never heard of them before; they are not among the 293 sects mentioned as having places of worship in the list given by Whitaker. However, it is well known that the best work is generally done in silence. Although the *Herald* scoffs at medical men and medical science—*vide* page 26 of the February number—yet it advertises a professional preliminary school for girls. To quote from the prospectus: "The object of this school is to provide girls with a sound all-round education, and at the same time prepare them for these professional preliminary examinations so that they can, while with us, or later on, register themselves as medical students without further preparation." This school is at 5, Osnaburgh-terrace, and the same address is given as being a boarding-house for Wallace-ites. Now we should very much like to know how the professional preliminary girls and the Wallace-ite boarders are all to be accommodated in the same house consistently with the laws of healthy housing, unless, indeed, the number of both classes is extremely small. Is the house run upon a kind of Box and Cox arrangement, or do the professional preliminary girls only come for instruction during the day? or how are things managed? There are a number of other interesting advertisements, e.g.:—"Monthly nurse. Vegetarian, hygienist, teetotaler? Diploma. No doctor necessary. Mrs. ——, ——, N.W." If no doctor is necessary the professional preliminary girls will not get much work out of the followers of the *Herald of Health*. Fads such as this paper advertises do not as a rule do much harm, but we most strongly object to people being allowed to sell so-called non-poisonous preparations of aconite. Already one unfortunate man has died after taking a dose of Wallace's specific, No. 1, or, to quote the verdict of the coroner's jury, "from cardiac failure produced by a poisonous dose of aconite contained in a bottle labeled Wallace's specific, No. 1." The sale of this nostrum, even when labeled "Poison," ought to be sternly put down altogether or else its composition should be inscribed on the containing bottle or packet.

THE MIDWIVES QUESTION IN VIENNA.

THE interesting communication in THE LANCET of Feb. 6th from our own correspondent in Vienna on the lamentable state of medical practice in that city is worth much consideration. It shows that even in a State which regulates medical and midwives' practice more than is done here medical practitioners are badly protected from gross evils. The article is, indeed, full of instruction. The legislation in Austria, which requires insurance against sickness by working men is about to be extended to employers and tradesmen, and doubtless, implies the further degradation of the remuneration of medical men. Unqualified practitioners continue to increase. The competition of the hospitals giving gratuitous treatment is on a huge scale. And midwives do a great deal not only of midwifery practice but of general practice, especially among children. They dissuade parents from sending for medical men by saying that the practitioner will notify their cases and lead to the expense of disinfection. The impression conveyed of the intelligence of these midwives is very poor. They deal in charms. They treat eye diseases of new-born children with milk or with urine, and if convulsions occur put on the mother's wedding veil. Those persons who are concerned for the plight of women attended by midwives in this country and also wish to protect them by legislation and registration should study these revelations and introduce securities that midwives, if they are to be registered, shall also be restricted to very plain and palpable duties.

"CHILD STUDY."

A PUBLIC meeting was recently held in Manchester at Owens College in connexion with a local society for "child study," which is now to be made a branch of the national association for the same purpose. Dr. Ashby, on the proposal of Principal Ward, presided, and said that a small association was formed in Manchester last year and that now affiliation was sought with the British Association for Child Study. To those who had read the delightful essays of Professor Sully it was not necessary to explain the object of the society. During the last few months some of their candid friends had asked if they were going to experiment on newly-born babies—if they were going to put pepper or salt on their tongues to try to find out at what exact period they appreciated these useful condiments. They were asked if they were going to repeat the experiments on the prehensile faculty of infants in order to demonstrate their affinities with our lower relations, and if it was intended to make the nursery a temple and the baby an idol. They had no intention of doing any of these things, but would work under the direction and with the help of some distinguished psychologists and biologists, and they would also seek the assistance of mothers, nurses, and teachers—"all those, in fact, who were the associates of the infant in its early days and had the shaping of its destinies. There was still a good deal of rule-of-thumb work in the British nursery." Professor Lloyd Morgan of University College, Bristol, gave an address on the aims and

Hosted by Google

methods of such a society. He based the primary claim of child study on the bearing it had on education and was convinced that systematically undertaken it would tend to give right ideas and to eradicate wrong ones, and thus be "influential on the practice of education." In the past psychologists had been too introspective, and had given the results of self-analysis, and had thus evolved a psychology of sages; but it was most desirable that they should make their science more thoroughly comparative by the investigation of psychological processes in minds at a lower stage of development. By working hand-in-hand "the trained psychologist and the teacher by profession would attain to results which in the largest and fullest sense would tend to give right ideas and eradicate false and erroneous notions." Professor Morgan said the subject of perception and conception as exercised in tolerably close touch with sensory data would, he was sure, amply suffice for the session's work. He indicated what could be done in testing the sensory endowments. The range and accuracy of vision, the perception of colour, the recognition of visual objects, experiments on hearing, observations on pressure perception, space perception, memory, and the subject of association and suggestion were among the points discussed. Dr. Mumford, who has taken the initiative in the formation of the local society, in which he was ably backed by Professor Alexander, proposed, and Professor Wilkins seconded, a vote of thanks to Professor Morgan for his address. The study of child life and the patient watching for the gradual development of the physical and mental faculties—for the first smile of recognition—afford as fascinating a study as any young mother wishes for or can imagine; but the "scientific" observation of "their powers of estimating angular value or relative weight" will perhaps only be thoroughly appreciated by the "new woman." And the nursemaids, whose aid Dr. Ashby invokes, must surely be required to undergo training and "registration" before being called on to give the results of their observations. Professor Morgan says, truly enough, that the child's coöperation must be obtained, and that if while making experiments on his perceptive powers the "trained psychologists" sat solemnly by, taking mysterious notes, he did not think the results would be satisfactory. "We must place ourselves as nearly as might be on the same plane as the children. What we desired them to do we too ourselves must do. The observers' notes should be written up afterwards." These are most judicious remarks, showing already some knowledge of child life. It would be charming to see the professors become "as little children," and most interesting to know the verdict of the experimented on the perceptive faculties of the experimenters. There is much we should like to learn as to the "dawn of intelligence," and we wish the society every success.

THE NOTIFICATION OF MEASLES.

IT has for a long time now been a disputed point as to whether or not measles should be included among the notifiable diseases. At first sight it would appear inconsistent not to include within the Act a disease which is at the same time one of the most infectious and fatal of those which prevail in this country. Further consideration, however, will quickly show that there are many difficulties in the way of making the fact of notification a useful means of checking epidemics, and it has actually been shown that in many places where such a system has been adopted the epidemics have been quite as widespread and uncontrollable as before. In times when no epidemic is in existence it is probable that the notification of odd cases might occasionally lead to prevention of further spread, but when an epidemic has once set in the difficulties become enormous. The disease spreads so rapidly that to ensure any chance at all of stamping it out at its commencement a large staff would always have to be kept in readiness, which would lead to a very great expenditure and a very doubtful gain. The onset of measles makes it a very difficult disease to identify in the early stage, for, unlike the more definite onset of scarlet fever with the early appearance of a rash, its first symptoms are often treated with the family remedies for a cold, and it is usually not until the seeds of infection have been widely scattered that its nature is definitely recognised and measures are undertaken to prevent it spreading. On the other hand, if this disease came within the Act it might, perhaps, teach the public to look upon it with rather more awe, which it is rightly entitled to by reason of its great fatality. We have before us a report on this subject which Dr. Corfield has made to the vestry of the parish of St. George Hanover-square, in which, after due consideration, he advises that body not to adopt the system of notification. His inquiries into the subject show that the plan has failed to produce any effect in many places where it has been adopted and he does not think that the doubtful advantages received would in any way justify the enormous expenditure which the adoption of such a scheme would necessitate. Among the methods for checking an epidemic Dr. Corfield has great faith in the early closing of infant schools, which, if adopted soon enough, should be very beneficial, and he further dispels the illusion that children catch the disease just as easily after the school is closed by playing with each other in the courtyards and streets, for fresh air is always an antagonist to disease, though we are afraid that the germs may live comfortably, even if they do not thrive, in the stagnant and darkened atmosphere which occupies the limited spaces between so many London dwellings.

CENSURE BY A CORONER.

FROM a report in the *East Anglian Daily Times* it appears that on Feb. 4th an inquest was held by Mr. J. Harrison, coroner for Essex, at Wivenhoe, touching the death of Henry Robert Childs, aged fifty-six years, a painter. The body of deceased was found in the Colne in about three feet of water and four or five yards from the edge. After the tide had gone down footmarks could be traced for sixty yards down the sand from the sea wall. During the inquiry the jury expressed a desire to know when Dr. Hewlett of Wivenhoe last attended deceased and for what malady. In furtherance of this wish the coroner despatched his officer to ask Dr. Hewlett for information or to request his attendance. Dr. Hewlett replied: "I decline to give any information here, as I consider it unprofessional to give evidence and testimony to a police officer which should be given only by the medical man in person at the coroner's court. I was prepared and, moreover, perfectly willing to attend the inquiry as a witness if desired." On the message being reported to the coroner he said to the officer: "You tell Dr. Hewlett from me that if he sends me messages like that I shall commit him for contempt of court, and he will find himself in a funny position." Subsequently he informed the jury that Dr. Hewlett had sent back "a most insulting message" and that unless he had an apology he should certainly have him before him next time he had an inquest in Wivenhoe. If the facts are correctly reported, we have no hesitation in saying that, in our opinion, Dr. Hewlett's action was consonant with both the spirit and the letter of the law. A medical man is not bound to state to a coroner's officer the evidence he would be able to give. Nor do we consider a verbal request to attend an inquest is sufficient. By the statute 6 and 7 Will. IV., c. 89, the first section enacts "that whenever it shall appear that the deceased person was attended ..... during his last illness

Hosted by Google

by any legally qualified medical practitioner it shall be lawful for the coroner to issue his *order in the form in the schedule* thereunto annexed for the attendance of such practitioner as a witness." We find no mention of any alternative method of demanding the attendance. In Jervis's "Coroners" it is laid down that "in all cases of sudden or violent death ..... it is desirable that a surgeon should be called as a witness, and if the deceased has been attended by a medical practitioner his attendance should be secured, care being taken that he is able to identify the body." We have repeatedly endorsed this opinion, and although the coroner in this case undoubtedly acted within his powers we think that he would have shown greater discretion if he had issued an order for Dr. Hewlett's attendance in the first instance. Failing that, however, there can be no doubt that on the presentation of the jury he should have adjourned the court for Dr. Hewlett's evidence on oath under subpœna. To say nothing of the serious inconvenience that may be caused to a medical man by being unexpectedly and peremptorily required to attend an inquest at once, we consider that both by courtesy and law he has a right to expect a formal summons at due notice. A coroner's court is one of first instance and hearsay evidence is admissible, but nevertheless this should be taken only as a substitute when direct testimony on the point at issue is not procurable. Again we quote Jervis: "If during the inquiry it appears that there are persons whose testimony is material and who are not in attendance, the coroner may *issue his summons* to compel their attendance," and "the coroner, being guided by the information he has received, usually sends a message to those whom he thinks material. Should they neglect or refuse to attend the coroner, as incident to his office of judge of a court of record, has authority to issue a *summons* to compel their appearance ..... and he may, if necessary, issue a *warrant*. If a witness resists the warrant the coroner may commit him for contempt." If this is a correct statement of the law it is clear that in the case under discussion Dr. Hewlett was not guilty of contempt and therefore not subject to committal. We trust that there is some fault in the report of the proceedings at the inquest, for, failing that, we should be inclined to think that the coroner could with more justice be called to account for exceeding his jurisdiction than that Dr. Hewlett should be committed by the coroner for contempt. It may be in the recollection of our readers that some years ago, when the late coroner for Middlesex insisted upon fully exercising his legal powers with regard to the holding of an inquest and the manner of conducting it, the subject was made the matter of an interpolation in Parliament, and that the Home Secretary, whilst admitting that the coroner's procedure was within the four corners of the law, hinted at the clipping of coroners' wings unless they acted with more discretion.

MODERN LAW AS TO VACCINATION PROSECUTIONS.

ON several occasions recently prosecutions of defaulters under the Vaccination Acts have failed owing to the omission on the part of the prosecutors of what was held to be a necessary detail—i.e., the vaccination officer had not been furnished with special written instructions to take proceedings in each case. It is difficult to ascertain upon what grounds it has been held that such instructions were essential, but it is certainly a fact that the ardour of boards of guardians has in some instances been somewhat damped owing to cases in which this detail was omitted having been dismissed. It appears, however, that the legal profession has recently been looking up the law on the subject, and has now arrived at the same position as has, we believe, been held all along by the Local Government Board. A decision having been given at Ipswich that it was not necessary for the guardians to issue separate instructions for prosecuting in each case, or, indeed, any instructions at all, reference was made to the Court of Appeal and the decision was upheld. Mr. Justice Wright, in giving judgment, is stated to have said that the law had been altered, but we fail, having regard to the fact that there has been no recent legislation on vaccination, to understand how this can have been the case. However, his judgment was that the vaccination officer could proceed without any express instructions, and Mr. Justice Bruce, in concurring in the decision, pointed out that the vaccination officer was, by the fact of his appointment, entitled to take proceedings. This decision will do much to clear the air, and it is to be hoped that clerks to all boards of guardians will pay due attention to it. We note that the judgment bore fruit on Feb. 11th at West Ham, when some twenty defaulters were brought before Mr. Baggallay and orders in all cases were made. One of the defaulters asked to see the authority of the vaccination officer, and it turned out that he had received only general instructions. It would seem, however, that not even these are now considered necessary, and the defendant having failed to carry this point endeavoured to obtain relief under the recent report of the Royal Commission. Mr. Baggallay, however, replied that a magistrate's duty was to obey the law, and that the law had as yet no concern with "conscientious objections."

MOVEMENTS OF VOCAL CORDS.

THE last volume of the *Philosophical Transactions* contains the record of an important piece of work in reference to cerebral localisation by Dr. Risien Russell. The title of the paper is "The Influence of the Cerebral Cortex on the Larynx," and it describes in considerable detail the experimental work which the author of the paper had undertaken and carried through with the object of showing to what extent, and in what degree, the various laryngeal movements are represented in the cerebral cortex. It is only natural that Dr. Russell's recent experiments, in which he was able to demonstrate the presence in the cortex of centres for various ocular movements other than those merely of conjugate deviation, should have suggested a similar line of research in reference to those of the vocal cords. It will be remembered that these experiments on ocular movements were undertaken at the suggestion of Dr. Hughlings Jackson, who thought that by dividing the muscles which subserve the lateral ocular movements it might be possible, by stimulation of the area of the cortex subserving them, or of some neighbouring part of the cortex, to evoke other ocular movements. Such, indeed, proved to be the case, and in the present investigation, as has been said, a similar procedure was adopted to try whether it was not possible to obtain abduction as well as adduction of the vocal cords. The experiments were carried out, of course, with the animals anæsthetised, and in one series of experiments the movements of the cords were directly observed, while in another the results were graphically recorded by means of a tambour and kymograph. In many of the experiments also the abductor bundle of fibres in the recurrent laryngeal nerve was separated from the adductor bundle—a procedure which Dr. Russell had previously shown to be not only feasible, but comparatively easy. The cerebral cortex was stimulated under different circumstances. 1. When both recurrent laryngeal nerves were intact. Under these conditions adduction of the cord was usually obtained, but in the dog occasionally abduction was obtained, and in the cat an additional abductor centre was found corresponding closely in position to that of the centre from which abduction was obtained in the dog. The most

Hosted by Google

careful observation failed to reveal unilateral movement of the vocal cords or the slightest difference in the time or manner of their movement. 2. It was also found that if one laryngeal nerve were cut, the vocal cord of which the nerve was still intact could be equally well stimulated from either side of the cortex cerebri. 3. It was when the adductor fibres alone of one nerve were divided that there was first found evidence of the representation of abduction of the vocal cords in the cortex of the dog. It was found possible to evoke both abduction and adduction under such circumstances, but whereas both cords participated in abduction, only that cord of which the adductor fibres were intact in the recurrent laryngeal nerve was adducted. 4. If one recurrent laryngeal nerve were completely divided, and the adductor fibres only in the other, abduction of the cord of which the recurrent laryngeal nerve contained intact abductor fibres could be elicited on stimulation of the proper centre in either cerebral hemisphere, and if the adductor fibres in both nerves were divided—leading to a widely open condition of the glottis—excitation of the abductor centre led to still greater abduction of the vocal cords. The focus which has thus been marked out in the cortex cerebri of the dog is in the anterior composite and prorean gyri, and that it is probably the true abductor cortical centre for the vocal cords is made more likely by the fact that it is precisely in the same region in the cat's brain that the effect is to be obtained. But in the cat there is this great difference, that abduction can always be evoked on cortical excitation, whether the adductor fibres in the recurrent laryngeal nerves be intact or not, whereas in the dog it is sometimes necessary to divide the adductor fibres in one recurrent laryngeal nerve before it is possible to elicit abduction on cortical excitation. The result of the research, therefore, broadly stated, has been to differentiate centres stimulation of which causes abduction of the vocal cords. There are many other minor points of considerable interest referred to in the paper, in regard to which the original should be consulted by those interested, and Dr. Russell is to be congratulated not only on the results of his work, which are interesting and important in an unusual degree, but also on the care and ingenuity which he has shown in the various stages of the research and the lucid manner in which he has detailed his procedures.

ANTI-VIVISECTIONIST TACTICS.

IN a letter which appears in our columns attention is called to the fact that the Anti-Vivisectionists' Society is at present using most unscrupulous methods to lead the public astray on the question of vivisection. From personal experience we know that this is the case and that a large number of well-meaning but thoughtless individuals are at present carrying about petitions which they can certainly not understand and which are calculated to do an immense amount of harm amongst those who have no opportunity of knowing that much of what is stated in these petitions is absolutely false and much intentionally misleading. These petitions are carried to every drawing-room meeting, and to church meetings of all kinds, and a number of signatures have been obtained, especially from people who do not take the trouble to inquire into these matters for themselves. As our correspondent points out, Sir Spencer Wells, a man who is said to have relieved an enormous amount of suffering amongst women, could not have obtained the results he did had he been so foolishly sentimental as to put the lives of a few animals against the number of lives he has been able to save and the amount of suffering he has succeeded in alleviating. Even those who have followed him, although they have done no animal experiments themselves, must recognise their indebtedness indirectly to the earlier experiments on animals. Unfortunately there are always a large number of people who are easily influenced by specious statements and plausible arguments, especially when they come from people who apparently speak with authority, but we should like all who are asked to sign this petition to insist on a definite answer to the following question: Could the antitoxic treatment of diphtheria have been evolved and could it be carried on without experiments being made on animals? Having got an answer to this question we should like them to ask the following: Is it true or is it not that there has been a great diminution in the percentage-mortality of diphtheria—representing last year in the Metropolitan Asylums Board Hospitals alone a saving of 250 lives and an enormous amount of suffering to the children of those to whom this unscrupulous circular is addressed; whilst in a certain class of case—that following scarlet fever—the death-rate has been reduced from over 60 in a 100 to less than one-tenth of the original mortality? When these questions are satisfactorily answered people may begin to consider whether they will sign these petitions or not, but until then all who have children of their own will be wise to withhold their support from a movement which is kept alive by faddists, many of whom do not object to taking animal life or the infliction of animal suffering where their own selfish interests and pleasures are concerned. We are perfectly willing to discuss this matter with those who are consistent throughout, but for most of those engaged in this so-called crusade we hope that honest people can have little but contempt; indeed, if their methods were not so persistent and so unfair most people would wish to forget them as soon as possible.

MENTAL DEFECT IN CHILDHOOD AND INCREASE OF INSANITY.

IN the House of Commons questions were asked a few nights ago concerning the alleged increase of insanity, and also as to the discrimination of children who are weak-minded only from those who should be sent to an asylum as imbecile. The number of insane patients in institutions has increased largely of late years; but the question as to actual number of persons becoming insane is one upon which authorities differ. A special report has been prepared by the Lunacy Commissioners, which is now in the printer's hands. Whatever may be shown by that report as to increase of the numbers of lunatics or otherwise, it is very desirable to consider whether any public means can be taken to lessen lunacy in adults by better care of the mental conditions of children. It is frequently found that a brain unstable from early years becomes insane under the pressure of life, and one means of prevention worthy of consideration is the discrimination of such children and their care. There are children of imperfect intelligence and low mental power in judgment, memory, and social sense whose bodies and brains are not so far abnormal as to justify their certification as imbeciles; again, there are children distinctly mentally exceptional, not necessarily dull in intellectual power, but destitute of moral sense and the knowledge of right from wrong, or of the decencies of social life and conduct, who are never truly sane, children of unsound mind though not imbecile. There are no sharp lines of discrimination between these groups and normal children that can be defined by single defects indicating mental weakness. We would suggest that for practical purposes an individual child should be classed and dealt with on a medical report showing defects in health and in points of bodily development, especially of the head, palate, and features; also describing abnormalities in gait, in expression, movements, or response in action as well as speech, while the mental power is tested by questions as to knowledge, judgment, and memory. It is important that some facts should be

Hosted by Google

stated as well as an opinion expressed by the medical certificate in any case of mental deficiency. This question of discriminating children of feeble mental power from imbeciles is a part of the reference made by the President of Council to the Departmental Committee appointed to report on the education of children of defective intellect.

THE APPRECIATION OF THE GENERAL PRACTITIONER.

THERE are some indications that the rage for specialism has reached its height, and that the public are coming to see that they must rely for medical aid in nine out of ten of the medical emergencies of life on the general practitioner. Not only so, but for the general direction of life, for making the best of a person's physical and mental constitution, more will depend on the ordinary adviser, provided he be a man worthy of his vocation, than upon a consultant, however expert, who sees the patient once or twice in a lifetime. The *New York Medical Record* has a leading article on this subject, based on some remarks by no less a personage than President Cleveland, who, at a recent meeting of the semi-centenary of the Academy of Medicine, sounded the praises of the old-school practitioner who met all the emergencies of treatment in the last generation. He was supported in this view by Dr. Jacobi, who, speaking of the actual needs of medical practice of to-day and giving specialism its due meed of praise, expressed himself strongly in favour of re-instating the all-round man. It cannot be doubted that with the ever-improving qualification of the general practitioner the force of these considerations will gradually prevail.

THE PROPOSED SUPERANNUATION OF LOCAL AUTHORITIES' OFFICERS.

WE are glad to see among the Bills introduced to the House of Commons by private Members one which has for its object the superannuation of the officers and servants of local authorities. This latter term has a wide significance, as it includes practically all local bodies having sanitary and parochial functions, outside boards of guardians and other authorities, to which the Poor Law Officers Superannuation Act of last session relates. Thus we see the councils of all boroughs and urban and rural districts, school, highway, burial, and joint boards under Public Health Acts, and public libraries and baths commissioners and vestries named as coming within the definition. The Bill proposes to secure for all officers and servants as defined superannuation allowances on the basis of the Act just referred to, which Act, in so far as it can be made to apply, is printed in a schedule to the Bill, the main measure being made to refer to the schedule as extending to local authorities in the same way as to Poor-law authorities, with such differences only as are essential to the proper reading of the Act as thus extended. Thus, clauses of the Act relating to the title of officers and servants to superannuation allowances, the scale of such allowances, the method of reckoning services, the power to add years to actual service for the purposes of the Act, cases of subsequent appointment, forfeiture of claim on account of fraud, the return of contributions in certain cases, scale of contributions, and decisions of questions, together with some other provisions of the Act, are incorporated in the schedule as now set out in clauses 2 to 14 of the Act. Existing officers and servants may write themselves out of the scope of the proposed measure, as in the main Act, and any person doing so will remain subject to the provisions of the Metropolitan Officers Superannuation Act of 1866 if he be in the service of any authority to which that Act applies. Otherwise that Act is to be repealed. "Officer" means every officer in the service of a local authority and every assistant overseer and vestry clerk, except officers on the teaching staff of a board school. We learn that already public vaccinators are busying themselves in the direction of taking steps to make this proposed measure a means of securing to them the benefits denied under the Act of last year. We hope that they will be successful. The whole Bill has our sympathy, no reason appearing for the withholding from the officers coming within its scope the benefits which are now allowed to those in the Poor-law service. We cannot imagine that the House of Commons is likely to stand in the way of the superannuation of men who have devoted themselves to the service of the community in matters of public health, education, and cognate matters. This is an age of pension schemes, and where, as in the present case, authorities propose to reimburse themselves by a system of deferred pay for the granting of an old-age allowance to their officers and servants there seems no objection to the scheme. The servants of the Crown already possess the privilege, and now the Poor-law has a similar privilege for its officers; the present session will, we trust, witness the enactment of the Bill before Parliament, either as it stands or, at any rate, substantially as now drawn.

A NATIONAL PHYSICAL LABORATORY.

UPON Feb. 16th a deputation of scientific men headed by Lord Lister waited upon Lord Salisbury to induce the Government to supply funds for the foundation and maintenance of a National Physical Laboratory. The initial expense it was said would be £30,000 and the annual cost of maintenance, £5000. Lord Salisbury, in reply, acknowledged the extreme importance of the matter, but could not undertake to give any pledge in the absence of the Chancellor of the Exchequer. With regard to expense he said two important words which appeared in the printed statement had been omitted by the speaker. The amounts mentioned were in that statement put down as being necessary "at first." He had known modest movements which started with thousands to end in millions. He threw out as a suggestion that instead of asking the Chancellor of the Exchequer to pledge himself to outlay to which no bounds were set, some limited scheme of standardising for stopping adulteration should be pressed upon the State, and the question of general research reserved or allowed to depend on private munificence. We should be glad to see Lord Salisbury's scheme adopted, for the prevention of adulteration is a most important matter. He is quite right as to the probable increase in the expenses; and no one who remembers the increase of Mr. Forster's education rate of threepence in the pound to close upon a shilling can think otherwise.

THE WATER-SUPPLY OF CHICAGO.

THE city of Chicago, in spite of the great engineering work that was carried out in 1893, has not yet secured a satisfactory water-supply, and we understand that the Department of Health has considered it necessary to shut off the town water from as many as 250 public schools with an aggregate of 208,000 scholars. The task of making special arrangements for the supply of water upon so large a scale must be a very formidable addition to the duties of the School Board. The first impression of the visitor to the city on looking out upon the broad expanse of Lake Michigan, and learning that it is an inland sea of singularly pure and potable water, is that here at least the question of water-supply is solved by nature, whatever the dimensions or demands of the city may be which stands upon the shore. But, in point of fact, the very abundance of the water is its bane. If a river of moderate dimensions flowed through the city there would be no fear of contamination. The simple expedient of placing the water intake above the sewage

Hosted by Google

outflow would make the city absolutely secure against this peril. But in Lake Michigan the volume of water is so vast that the flow is imperceptibly slow, and so long as any part of the city's sewage is permitted to flow into the lake there will be a danger of its drifting into the water intakes. Our own experiments made in 1892 (*vide* The Report of THE LANCET Special Sanitary Commission of Inquiry concerning the Water-supply of Chicago, U.S.A.—THE LANCET, April 8th, 1893) showed that this danger was notably reduced by putting the intake at a distance of three or four miles from the shore; but they also showed that this was no complete protection, and now the experience of the School Board confirms our experimental results and enforces the conclusion that complete isolation of the water-supply is the only safe and trustworthy course. Unfortunately for a community residing on the shores of a great lake, it is a course presenting many and special difficulties. In these circumstances it is no smal matter that it has a great reputation for enterprise and public spirit to maintain.

THE MEDICAL PROFESSION AND MASSAGE ESTABLISHMENTS.

WE think it quite time that forcible protest should be made in the name of the medical profession against the custom of advertising establishments, which, to put it mildly, are quack institutions, as places for the giving of electric baths and massage. The objects for which most of these establishments exist are perfectly well known and it is not our purpose now to deal with that aspect of the question. That is a matter for the police. What we do most strongly object to is their masquerading under the cloak of providing medical treatment. Electric baths, if properly given, are a very valuable method of treatment; but to try to give them in a metal bath is worse than useless, even if the metal be painted. The baths in two widely-advertised houses which were visited were ordinary metal baths; no questions were asked about the complaint from which the visitors might be suffering, and the whole style of the rooms, the "nurses," and the establishment generally left no doubt as to the purposes for which the places were used. These baths are advertised in the most respectable newspapers, and the advertisements are couched in such terms as to give the idea that the houses are places where definite medical treatment is carried on. This must be altered. Let the proprietors either use the expression in vogue in the eighteenth century for a like place—e.g., "bagnio"—or the old English word "stew." We are not now concerned with the morality or otherwise of the question, but we must insist upon the advertisements being so worded that the medical profession should not appear to have anything to do with such places. The police can surely do the rest.

THE POSITION OF THE AURICULO-VENTRICULAR CUSPS DURING SYSTOLE.

IT is usually taught in this country that during systole the thin edges of the auriculo-ventricular cusps "outside the attachments of the chordæ" (Foster) are kept flatly in apposition by the contraction of the papillary muscles simultaneously with the ventricle, and that the same muscular action keeps the cusps as a whole convex to the ventricular cavity. The pictorial representation of this state in transverse sections conveys the impression of the valves being locked up and bulging towards the auricle, an impression which is certainly erroneous. Dr. Cockburn Smith, in a letter in another column, calls our attention to a view held by many on the Continent and said by some to have originated with Parchappe. According to this the effect of the muscular actions we have referred to is to "pull down the auriculo-ventricular curtains," applying the valves one against another, and in the case of the left ventricle to the outer wall of that cavity, while in the right ventricle the approximated valves lie against the septum ventriculorum. Parchappe's book is valuable and interesting and his views, which, however, were not solely his, were in the main correct, as may be easily demonstrated. In a paper on the Action of the Valves of the Mammalian Heart, published by Dr. Noël Paton in the Laboratory Reports of the Royal College of Physicians of Edinburgh (vol. iv., p. 36) the same view in its essential points is maintained, and references are given to the works of Meckel, Mayo, Reid, Hope, and Burdach, who preceded Parchappe in entertaining it. Dr. Paton's experimental methods may be learned by consulting his paper, but anyone may convince himself of the truth of this view by purchasing the heart of a sheep killed by bleeding which has died with the heart in systole and dividing that organ so as to expose the interior of the ventricle with its taut cusps and contracted ventricle and papillary muscles. It may be readily conceived how such a disposition of these valves is calculated to strengthen their power of resisting intra-ventricular pressure when it is at its maximum at the commencement of systole and how so powerful a barrier against regurgitation quickly gains the upper hand in its struggle against distension, as the latter quickly subsides with the diminished size of the contracting ventricular cavity and the forward movement of its fluid contents.

PAR NOBILE FRATRUM.

THIS week we are able to lay before our readers two addresses of exceptional interest, full of references to events which have become historical, and commemorative of some of the greatest names in British medical science. Although the Hunterian Orations have for so many years been the congenial theme of practised speakers and writers, the subject is in no danger of becoming tedious or threadbare, for the story of John Hunter's life and work is incapable of compression within the limits of a single discourse, and the author of the oration each year has therefore considerable opportunities of selecting the topics for which he has a special preference. Mr. Christopher Heath has succeeded in everywhere manifesting a pleasant freshness and vitality, a sure sign of a speaker being both in sympathy with his subject and thoroughly familiar with the various developments which it has undergone in the hands of successive investigators. On account of its essentially practical nature John Hunter's anatomical and surgical work readily admits of being quoted from even under the very altered circumstances which have come to pass in the course of upwards of a hundred years, and in this respect he is perhaps placed at an advantage over his elder brother William, whose similarly distinguished career is outlined in the oration delivered by Dr. Hingston Fox before the Hunterian Society. Originality of mind and unwearied assiduity were the special attributes of these two brothers. They each had the satisfaction of knowing that their work was appreciated by their contemporaries; and more appropriate monuments to the memory of such men there could hardly be than their own museums, the one preserved by the Royal College of Surgeons of England and the other by the University of Glasgow.

THE RECENT LUNACY COMMISSION AT BOLTON.

AT the Bolton County-court, during the last week in January, Mr. Fischer, Q.C., one of the Masters in Lunacy, was engaged, with the assistance of a jury, in holding an inquiry respecting the state of mind of Mr. Arthur Knowles, a Bolton cotton spinner. The proceedings were instituted on the petition of the wife, and the case, which was of a

Hosted by Google

somewhat unusual and painful nature, created much local interest. In such cases the rule is laid down that evidence relating to the presence of insanity in the alleged lunatic must be restricted to a period of two years preceding the inquisition. The testimony of the witnesses, both lay and medical, was of a contradictory character. Three medical men, including the family attendant, testified to the defendant's mental incapacity; on the other hand, several experts gave it as their opinion that he was capable of managing his affairs. Between the latter and the petitioner's counsel there was a pretty display of dialectical fencing. The most remarkable feature in the case was that it was admitted by the defence that in May, 1895, the defendant was of unsound mind. Previously to this he had several attacks of influenza, the last of which was followed by a slight attack of melancholia. Always of a religious turn of mind, he became more intensely so, declared he was Jesus Christ, and at Ilkley Moor on one occasion denuded himself of his clothing in a public place. Subsequently he associated himself with a peculiar sect who believed in faith-healing, and roamed about the country attending holiness conventions, returning to his home accompanied by other believers, his inferiors in social status, to whose presence in the house his wife naturally objected. Space forbids entering into all the salient features of the case, but there can be no doubt that the verdict arrived at by the jury was the correct one—viz, that he was of unsound mind and incapable of managing his affairs, for it is safe to say that if left to his own devices his religious mania would have become more intense, and hopeless insanity would probably have supervened.

BY the result of the election on Monday last for the Bridgeton division of Glasgow another member of the medical profession obtains a seat in the House of Commons. Sir Charles Cameron, Bart., M.D., LL.D. Dub., had a majority of 125 votes over the unsuccessful candidate, Mr. Scott Dickson, the Solicitor-General for Scotland. Sir Charles Cameron represented Glasgow in Parliament from 1874 to 1885 and Glasgow (College division) from 1885 to 1895, when he lost the seat. With the political aspect of the election we have nothing to do, but we may rejoice at the fact that the ranks of the medical profession in Parliament (thanks to the recent elevation of Sir Joseph Lister to the Peerage we are able to use the more comprehensive term) are strengthened by the accession of a distinguished representative.

A MEETING of the Executive Committee of the Society of Members of the Royal College of Surgeons of England was held on the 16th inst., when the following resolution was unanimously agreed to: "That a requisition be forthwith prepared and forwarded to the College, in accordance with the regulations, asking the Council to call a special meeting of Members at an early date, to consider the results and validity of the recent poll of the Fellows, and other matters of importance to the Members."

AT the next meeting of the Neurological Society, which will be held in the rooms of the Medical Society, 11, Chandos-street, on Thursday evening, March 4th, at 8.30 P.M., communications will be made upon Muscle Spindles, by Professor Sherrington, F.R.S., Mr. Victor Horsley, F.R.S., and Dr. F. E. Batten.

DR. DE HAVILLAND HALL'S second Lettsomian Lecture on Disease of the Nose and Throat in relation to General Medicine was delivered before the Medical Society of London on Monday last, and will be reported at full length next week. We regret that the pressure upon our space has made the delay in publication necessary.

THE Mercers' Company have granted 1000 guineas to the special appeal for £100,000 now being raised for Charing-cross Hospital. The Leathersellers' Company have also granted £100, the Brewers' Company 20 guineas, the Cutlers' Company 10 guineas, and the Scriveners' Company 10 guineas to the same fund.

ON Wednesday next, Feb. 24th, at 8 30 P.M., in the reference library room of the London Institution, Finsbury-circus, Mr. Victor Horsley F.R.S., will deliver the second of the Hunterian Society's lectures. The subject will be Torticollis and its Treatment. Members of the profession will be welcomed as visitors.

THE annual general meeting of the Medical Defence Union will be held at the rooms of the Medical Society, 11, Chandos-street, Cavendish-square, W., on Thursday, Feb. 25th, at 5 P.M. Mr. Victor Horsley, F.R.S., will take the chair and move the adoption of the annual report.

MR. BANCROFT, as the result of his readings from Dickens's works, which we understand he intends to resume next winter with the same object, has made gifts to various hospitals in London and the provinces of sums exceeding £3000.

THE council of the Sanitary Institute have accepted an invitation from the City Council of Leeds to hold a sanitary congress and health exhibition in that city in the month of September next.

SIR WILLIAM BROADBENT was presented on Wednesday last, in the library of St. Mary's Hospital medical school, with a service of silver plate in recognition of his valuable work as senior physician.

ON Thursday evening last Dr. J. C. McVail read a paper before the Epidemiological Society entitled—"The Royal Commission on Vaccination: a Review of the Dissentients' Position."

THE International Sanitary Conference at Venice has held two meetings on the 16th and 17th inst., when the measures adopted by various nations for checking the spread of epidemics were discussed. We hope to be able to publish some account of the proceedings of the Conference in future issues.

AT the recent election for the post of assistant surgeon to St. Mary's Hospital Mr. H. S. Collier, F.R.C.S. Eng., obtained the appointment.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The fifth meeting of the session was held on Feb. 10th in the Medical Library of University College, Dr. Aust Lawrence, President, being in the chair. — Dr. F. H. Edgeworth showed a patient with Intra-thoracic Tumour. Dr. Symes and Dr. Broom remarked on the case.—Dr. T. Fisher showed numerous Pathological Specimens recently added to the Bristol Royal Infirmary Museum.—Mr. C. W. J. Brasher showed a modification of Hale White's Tongue Depressor with glass shield for infectious cases.—Dr. Michell Clarke and Mr. Morton read a paper on a case of Abscess of the Lung, with operation. Dr. Elliott, Mr. Ewens, Dr. Parker, Dr. Fisher, Dr. Harrison, and Dr. Skerritt discussed the subject.—Dr. B. J. Baron read a paper on the Symptoms and Treatment of Empyema of the Maxillary Antrum, with results of operation in eight cases. Mr. Harsant and Professor Fawcett spoke on the paper.—Dr. Parker read a paper on the Diagnosis of Certain Diseases Allied to Rheumatism. Dr. Harrison made some remarks.

The Lancet Special Commission ON THE METROPOLITAN WATER-SUPPLY.

I.

LONDON is supplied with water partly by deep wells, but chiefly by various water companies. A comparatively small amount of water only is derived from the wells, which, with one exception, are all in the hands of private individuals or of companies. The quantity of water which can be obtained from wells has lessened year by year, for the level of the underground water has sunk. No statistics are available to show the daily amount which is derived from the deep wells, but compared with that supplied by the water companies it is inconsiderable. Of surface wells it is possible that a few remain. Some moveable pumps are still used by builders in the Chelsea district, but it is unlikely that much of the water is used for drinking. Of public pumps in London few, if any, remain. One of the last to go was the historic one of Aldgate, but for years before its removal it had been supplied, not, as the people in the neighbourhood supposed, from a local source, but by water laid on from the mains of the New River Company in accordance with the directions of the tactful and sagacious medical officer of health for the City of London, who, finding that the local water was extremely impure, and knowing that the inhabitants would not tamely submit (if they knew it) to any alteration in their cherished water-supply, by a pious fraud allowed them for years to pump water from the New River supply. And it was not until the pump was replaced by a tap that complaints were rife in the district.

The well of St. Govor in Kensington-gardens was formerly derived from a spring, but the saint has deserted the shrine, and the water, it is to be feared, has lost its healing efficacy. Practically, surface wells and springs in London have ceased to exist, dry wells affect only the few proprietors of them, and the great bulk of the water supplied to the district is brought by the water companies.

In the present article we propose to give a brief and necessarily incomplete sketch of the history of the London water-supply of the past; secondly, to define the metropolitan areas which are affected by the various water authorities which supply them; and thirdly, to give a brief description of the area of distribution of each metropolitan company.

EARLY HISTORY OF THE LONDON WATERWORKS.

The site of London was by nature bountifully supplied with water. The Thames was a large pure river and there were many springs in the town itself and in the immediate neighbourhood. Little is known about the water-supply of Roman London and few traces have been found of it; but this does not, of course, prove that during the Roman period there was not a really well-arranged water-supply. We know from recent excavations at Silchester that the arrangements there were extremely thorough and efficient. There were public baths and a large sewer which discharged beyond the walls of the city. It is probable that London and other cities in Roman times were equally well supplied, but naturally in the case of a city like London, where changes have constantly been going on and each generation of citizens has more or less destroyed the work of former ones, traces of the earlier civilisation are not frequently found. On the other hand, in the case of Silchester, which till recently remained undisturbed from the time it fell into ruins, it has been possible there to see clearly how perfect the arrangements were.

In the time of the Saxon dynasty London was a walled city with seven gates: Doe Gate and Blynes Gate or Belins Gate next to the river, Lud Gate and New Gate on the wes Creple Gate and Bischops Gate on the north, and Oeld Gate on the east. The streams of Share Bourne and Lang Bourne ran into Wall Brooke, which rising in Fensbury ran through the marshes of Moorfelde, then passed under the city wall, and flowing in a south-easterly direction ran into the Thames at Doe Gate. The river of Wells was beyond the city wall and to the west. Tod's Well, Bad's Well, and Fag's Well sent water into its left bank; the Old Bourne and the overflow from St. Bridget's Well ran into the right bank. Of these streams the names survive. The Walbrook and Langbourne are no more seen, but they have given their names to City wards.

In the time of Henry II. an account of London was given by Fitz-Stephen, Thomas à Becket's secretary. He appears to have been annoyed by the number of the drunkards and by the chastity of the city dames,[1] but he spoke well of the water. "There are about London," he says, "on the north of the suburbs choice fountains of water, sweet, wholesome, and clear, streaming forth among the glistening pebble stones." The amount of water, however, soon became insufficient for the wants of the inhabitants. The courses of the streams in the city became reduced in size and in places covered by the building of houses, and the citizens were obliged to bring water from a distance. In the year 1236 a supply granted on the demand of Henry III. by Gilbert Sanford was brought from Tyburn by leaden pipes, and some years later conduits were built in various parts of the city,[2] from which water derived from this source could be obtained.

The Corporation of London provided for the cleansing and repairing of the springs at Tyburn for the Great Conduit in Chepe, and the records of 1329 give an account of the money paid for that purpose and for the beer provided for the labourers who carried out the work. The records of the City of London contain a good many entries showing the difficulties the authorities had with regard to the conduits and the water-supply generally. It was found necessary to appoint keepers of the conduit, and their chief duty appears to have been to see that the water was not stolen wholesale for the purposes of trade. In 1312 it was provided that brewers, cooks, and fishmongers should pay, at the discretion of the keeper of the conduit, for the water they used for business purposes. In 1337 there was a complaint that the brewers sent "day after day and night after night" and took tubs full of water to make their ale. After a discussion in full court by the mayor, sheriffs, and alderman it was decided that if any large tubs were in future sent to the conduit by brewers they should be forfeited and retained for the benefit of the conduit. The pipes which conveyed the water to the great conduit in Chepe passed from Tyburn to Constitution Hill, thence to the Mews near Charing-cross, through the Strand to Fleet-street. The pipes were partly above ground and therefore exposed to weather and to accident, and in 1388 complaint was made by some of the inhabitants of Fleet-street that through the breaking of the pipes their houses had become damaged by the overflow of the water. In 1390 permission was given to certain citizens residing in West Cheap to put up a conduit near the church of St. Michael le Quern, and that it should be supplied from the great pipe of the conduit opposite St. Thomas Acon. An old drawing shows that there were two lines of pipes one above the other, and it seems that the water in the lower pipe could be had gratuitously by anyone who wanted it for drinking or for household use, and that certain money was paid for water supplied by the upper pipe. The money thus obtained was applied to keeping the conduit in repair and paying the attendant in charge of the place. An entry in the City Records, 1415, tells how the mayor and corporation had ordained that the brewers who rented the fountain were not to draw any water from the small pipe below on pain of fine. As the water-supply became more and more inadequate for the supply of an increasing population riots occurred at the public conduit between the water

[1] Urbis matronæ ipsæ Sabinæ sunt.

[2] The first public cistern was the great conduit in West Cheap. It was lined with lead and the structure itself was of stone. The other conduits built in the city before the great fire were:—The Tun upon Cornhill, furnished with cistern, 1401; the Standard in West Chepe, supplied with water, 1431; the conduit in Aldermanbury and the Standard in Fleet-street, made and finished, 1471; the Standard in Fleet-street, Fleet-bridge, 1478; the conduit in Glass-street, 1491; the conduit in Glass-street, re-built by William Lamb, 1577; the Little Conduit in Stocks Market, re-built about 1500; the conduit in Bishopsgate, 1513; the conduit in London-wall against Coleman-street, 1528; the conduit in Aldgate, supplied with water from Hackney, 1535; the conduit in Lothbury and Coleman-street, near the church, 1546; and the conduit of Thames water at Dowgate, 1568.

Hosted by Google

carriers, so that the Lord Mayor by proclamation forbade people who resorted thither to come armed with clubs and staves. People who lived near the Thames obtained their water from carriers, whose business it was to deliver it from the river. It seems, however, that the people who lived in the lanes near the Thames objected to others passing without paying toll, and the water carriers or "cobs," as they were called, were a very truculent set of people. In 1438 the Abbot of Westminster granted to the Lord Mayor and citizens of London the privilege of taking water from the Manor at Paddington. The consideration to be paid by the city to the Abbot and his successors was two peppercorns on the Feast of St. Peter. It was provided, however, that if this work should interfere with the ancient wells used for the supply of the Abbey the grant should cease. In 1568 water was raised by machinery to the conduit on Dowgate-hill.

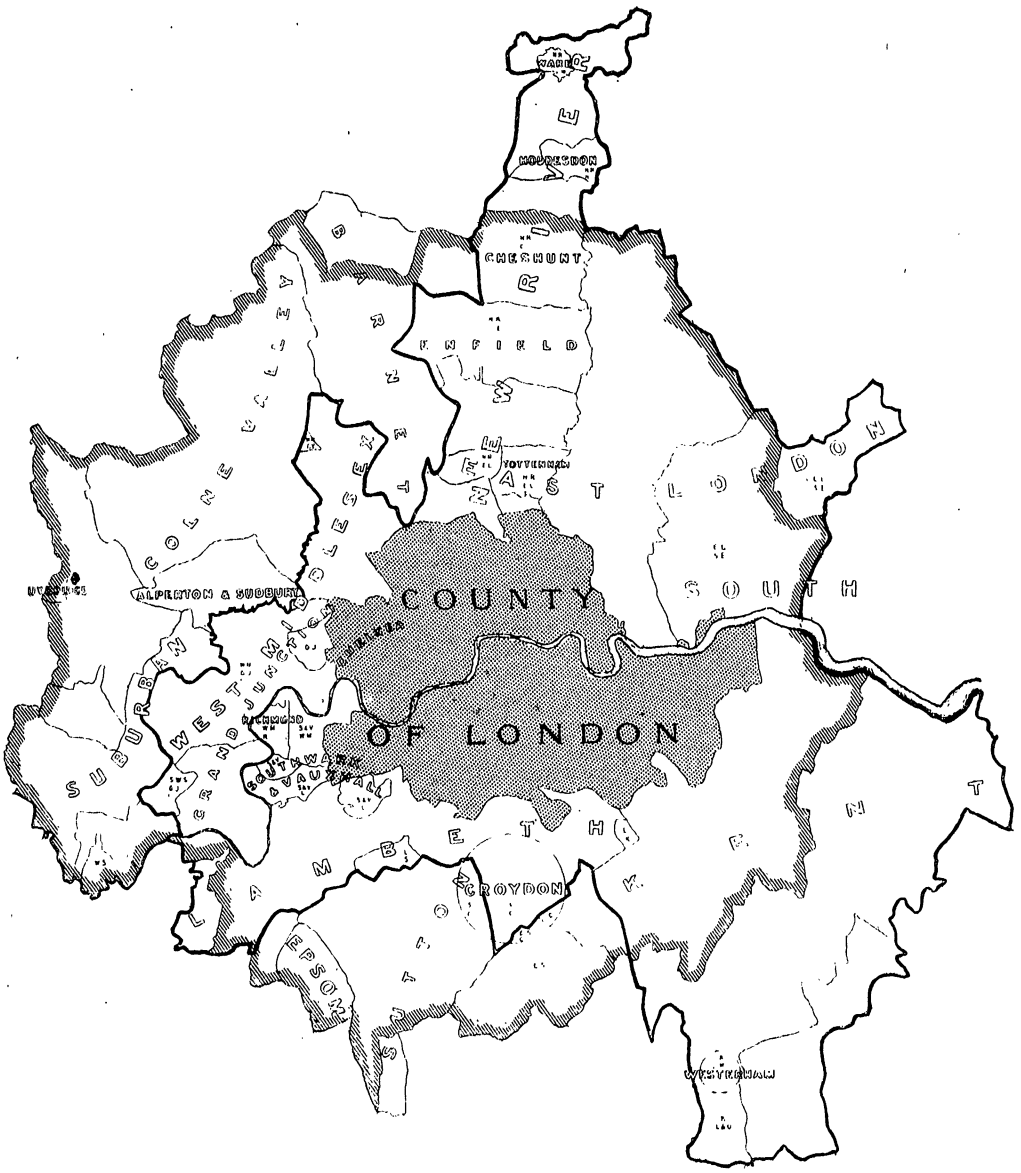
In 1582 a man named Peter Moris or Morice, an ingenious engineer, undertook to supply the city with water pumped from the Thames. The exact nationality of Peter Moris is open to doubt, but he was a Freeman of London. He put up an engine at the first arch of London Bridge, and by means of water wheels, which were driven by the river, he was able to force water through leaden pipes at such pressure that it was thrown over St. Magnus's steeple, to the great admiration of the mayor and corporation and the people who met to see the sight. He afterwards obtained the lease of the second arch of London Bridge and was thus enabled to increase the amount of water supplied. The Moris family built up an excellent water business, which was carried on by the family until the beginning of the eighteenth century, but the amount supplied was not sufficient for the whole of London. Thames water was conducted in leaden pipes to supply houses in Thames-street, New Fish-street, and Grass-street, and as far as the north-west corner of Leadenhall. The work was completed in the year 1582 on Christmas-eve. The City authorities paid the costs of the main pipe which conveyed the water to a standard made for that purpose. This standard, called the "Carrefour," had four spouts which pointed in different directions, and not only supplied the inhabitants of the houses near, who sent to fetch the water, but it served to cleanse the streets and discharged water northwards towards Bishopsgate, eastwards towards Aldgate, southwards towards the Bridge, and westwards towards the Stocks Market. It seems that the amount of water first supplied was not maintained, and Fleming, who continued Holingshed's Chronicles, says: "If the said water were maintained to run continually, or at least every tide, some reasonable quantity, as at first it did, it would have been well; but from 1566 it was much aslaked, through whose default I know not, sith the engine is sufficient to convey water plentifully." The standard at Cornhill existed until the Fire of London. It was sometimes dry, sometimes overflowing, and was frequently indicted as a nuisance for the latter reason by the inquest of Cornhill ward. The water business started by Moris was continued at London Bridge for one century and a half, and a tower was built on the bank as early as the reign of Elizabeth. The Great Fire destroyed some of the property, and in consequence of this litigation occurred at the petition of Mary Moris, widow of John Moris, against her brother-in-law Thomas and the trustees of the estate. In consequence of the fire the defendant, Thomas, tried to get out of paying her jointure, which was to have come out of the profits of the waterworks, and the petition was brought to enforce settlement of this and was successful. The trial showed that the water business was a very lucrative one. The progress of the New River ultimately interfered somewhat with the profits, and the proprietor then sold the property to one Richard Soames, a citizen and goldsmith, for £36,000. Soames was a financier and soon brought the business out as a company, with a capital of 300 shares of £500 each. In June, 1767, a fifth arch of the bridge was granted to the waterworks by the Corporation. The works continued until 1822, when they were removed just before the destruction of the old London Bridge and the property was sold to the New River Company.

Moris's water business was the first of the kind started in London, but he had imitators. In 1594 Bevis Bolmar erected a large horse engine at Broken Wharf, near Blackfriars Bridge, to supply the west part of the city with water. The undertaking did not prove a success, and the site was ultimately bought by the New River Company. In 1641 there was a project for bringing water from Rickmansworth. This, however, was not carried out. Maitland speaks of another establishment called the Merchants' Waterworks, which had a windmill in Tottenham Court Field and two other stations—one in St. Martin's and the other in Hartshorn-lane in the Strand—for supplying water from Tyburn.

In the reign of Elizabeth several schemes for the improvement of the water-supply were laid before Lord Burleigh. Of these, one was to bring water from Uxbridge to the north of London. An Act of Parliament was passed in Elizabeth's reign to allow the citizens of London to convey water from Hertfordshire to the city, and ten years were allowed for the completion of the work. Nothing, however, was done. The mayor and corporation of the city of London neglected a great opportunity of supplying the city with good water under their supervision. At that time, however, engineering was not a strong point amongst the members of the corporation, and the undertaking appeared, and actually was indeed, one not to be lightly undertaken. It was reserved for a private citizen, Hugh Myddleton, to carry out the work. On looking through the Records of the Corporation of London two things strike one with regard to the action of the mayor and corporation in all affairs connected with water. The first is that they were always extremely careful to insist on the fact that water for the poor to drink was the first consideration; and, in the second place, it is seen what stringent precautions were taken to punish offenders[3] who took a greater quantity of water than they were entitled to for trade purposes or who stole water from public sources for their own private benefit.

MUNICIPAL-LONDON, WATER-LONDON, AND POLICE-LONDON.

In the report of the Royal Commission on the London Water Supply the Commissioners found it well first to define the areas affected by the inquiry. The administrative county of London is nearly identical with the area called registration London by the General Register Office, but an area called Greater London by the General Register Office includes the districts within which the Metropolitan and City police have jurisdiction (see Fig. 1). But neither of these areas coincides with those supplied by the London water companies. The administrative county of London has an area of 121 square miles, but registration London does not include the hamlet of Penge, and Greater London of the General Register Office includes all parishes wholly situated within a circle of fifteen miles radius from Charing-cross, and all other parishes of which any part is included within a circle of twelve miles radius from Charing-cross. The total area is 701 square miles. The Commissioners in taking evidence gave the name Outer Ring to the area within Greater London and outside the county of London. This is the part which at the present time has the most rapidly increasing population.



The metropolitan water companies are eight in number; the area they supply does not coincide exactly with either of the areas mentioned. The districts supplied by these companies and the districts over which the companies have Parliamentary powers of supply are called Water London. The area includes the whole of the County of London and part, but not all, of the Outer Ring. It extends, however, beyond it in the north and north-east and in the south-east and south-west. Thus the New River Company's area extends to Ware in Hertfordshire; the East London as far as Romford in Essex; and in the south the Kent Company's area extends to Sundridge and Chevening in Kent; and to the south-west the Lambeth Company's area extends to Esher.

The total area of Water-London is 620 square miles. The Metropolitan water companies are:—The Grand Junction; the West Middlesex; the Chelsea; the New River; the East London; the Lambeth; the Southwark and Vauxhall; and the Kent. In some cases the Parliamentary districts of the water companies overlap one another—i.e., more than one company has a right by its Act of Parliament to supply a given district. In some cases where this has happened the

[3] The City records contain an account of how a resident in Fleet-street succeeded for a time in stealing water and the punishment that was meted out to him. On Nov. 12th, 1478, William Campton of Fleet-street was convicted of having tapped the conduit where it passed his house and conveying the water into his well, "thereby occasioning a lack of water to the inhabitants." The culprit was taken before the Lord Mayor and aldermen and punished in a rather striking manner. He was placed on horseback with a vessel like a conduit on his head and this filled with water which ran out of small pipes over him while he rode round all the conduits in the city.

companies themselves by private arrangements have settled their boundaries to their mutual satisfaction. There are instances in which small areas are still supplied by more than one company. Within the Parliamentary districts of supply of some of the companies water is supplied by other public authorities. There are also private water supplies in London, and not only in London, but throughout the district generally.

THE AREAS SUPPLIED BY THE EIGHT WATER COMPANIES.

Figure 2 defines the areas supplied by the eight different companies.

The New River Company supplies Highgate, Upper Holloway, Kentish Town, Highbury, Stoke Newington, part of Dalston, and the district between these places and the Thames, Hoxton, a great part of the City of London, including the Tower, and all the district along the Thames as far as Charing-cross. At Charing-cross the line of supply goes up Northumberland-avenue, takes in the northern part of Trafalgar-square, then goes in a northerly direction up the Haymarket and Poland-street. The line then extends in a northerly direction up the Tottenham Court-road as far as the High-street in Kentish Town. At the top of Tottenham Court-road the boundary area extends to the north-west to the Small-pox Hospital, Hampstead, then goes in a north-westerly direction to include the Hampstead district. Thus, roughly speaking, the districts supplied are the E.C., W.C., and the parts north of these districts. The company also supplies districts out of the metropolitan area, the total area being 59,520 acres.

The Chelsea Company supplies the districts which lie to the north of the Thames from Fulham to Charing-cross—Fulham, Walham-green, Chelsea, Brompton, Knightsbridge, Pimlico, Westminster, and part of St. James's. The northern boundary area of distribution runs from the Crab Tree at Fulham, up Crown-road, Lillie Bridge-road, Richmond-road, the Old Brompton-road, and then goes in a northerly direction to Prince's Gate and along Knightsbridge and Piccadilly to the north-east corner of the Green Park. The boundary then runs down the eastern side of the Green Park—that is, in the south-eastern direction—for about two-thirds its distance, and then passes to the north-east to include St. James's Palace, Carlton-terrace, and the southern part of Trafalgar-square. Here it is in contact with the New River area. The area supplied by the Chelsea Company is 3482 acres.

The West Middlesex Company has a less compact area of distribution than the Chelsea, with whose area of distribution it comes in contact from Princes' Gate to the Crab Tree at Fulham. The West Middlesex Company supplies Hammersmith, that part of Fulham now called West Kensington, South Kensington, and Kensington, the northern boundary of this part being the Uxbridge-road. The company supplies also the Regent's Park and Portman-square districts, extending as far south as Oxford-street, as far north as Brondesbury, and including the district of St. John's Wood. The area of the West Middlesex Company's water-supply is 17,280 acres.

The Grand Junction Company supplies the western suburbs, Shepherd's Bush, Wormwood Scrubs, and the district which is called North Kensington and Bayswater and part of Paddington. The total area supplied by the company is 29,760 acres.

The East London Water Company supplies part of Stamford Hill, Upper and Lower Clapton, Homerton, Hackney, Bow, Bromley, Poplar, Limehouse, Stepney, the London Docks, Shadwell, and the Isle of Dogs—that is to say, the parts north of the Thames from St. Katherine's in the east to the outlet of the River Lea, and in the county of Essex West Ham, Walthamstow, Leyton, Woodford, and Loughton. The total area of supply is 50,880 acres.

The area of distribution of the companies to the south of the Thames is not so easy to follow as that of the companies on the north because there is much more overlapping. As we have seen, to the north of the Thames, roughly speaking, the East London Company supplies the part popularly called the East-end, the New River Company the central districts and the parts to the north of them. The Chelsea Company supplies Chelsea and Fulham. In the case of the other two companies the distribution is rather less difficult to define. The Grand Junction has, as it were, a wedge of distribution in the centre of the area of the West Middlesex Company. The companies which supply the districts to the south of the Thames are the Southwark and Vauxhall, the Lambeth, and the Kent. Roughly speaking, the Kent Company supplies the south-east, the Southwark and Vauxhall the south-west, and the parts between these districts—that is, Kennington and Newington—are supplied by the Lambeth and Southwark Companies in common.

The Southwark and Vauxhall Company supplies Roehampton, Putney, Wandsworth, Battersea, Clapham, Newington, and Kennington, and part of Brixton is partly supplied by this company and partly by the Lambeth. The area supplied by the Southwark and Vauxhall Company is 19,040 acres.

The Lambeth Company, besides partly supplying the districts already mentioned, distributes water to Bermondsey, Rotherhithe, Peckham, and Dulwich. Its area extends through Dulwich, Forest-hill, Sydenham to the Crystal Palace, Anerley, Brockley-hill, Bell-green, and as far to the south as Beckenham. The Kent Company supplies parts of Hatcham in common with this company. The area of distribution is 39,360 acres.

The Kent Water Company, as far as its area of distribution is concerned, is the largest of them all; as far as population is concerned it is the least. It supplies parts of the south bank of the Thames, from Limehouse on the West to Woolwich, but its area of distribution includes Plumstead, Shooter's-hill, Blackheath, Eltham, and Southend. The total number of acres covered is 113,280.

MIDWIVES REGISTRATION BILL.

THE following is the text of the Midwives Registration Bill, now before the House of Commons:—

The chief object of this Bill is to enable the public, and especially such of the poor as are in the habit of employing midwives, to distinguish between those midwives who have been trained and have given evidence of being competent for their duties and those who have not.

This Bill provides that henceforth no woman shall call herself a midwife unless she has been placed on the midwives' register, and that in order to be placed on the register she must produce evidence either—(1) of having undergone a proper training and subsequent examination, or (2) of having (at the time of the passing of the Bill) been in *bonâ fide* practice as a midwife for a specified number of years. It is not proposed to make it illegal for a friendly neighbour to render assistance to a lying-in woman in an emergency.

A system of examination and certification by various voluntary bodies has been established for several years in the chief centres of population. It is proposed to place the duties hitherto undertaken by these voluntary bodies in the hands of a duly constituted Board, acting under State control. It is further proposed to make provision for the efficient regulation and supervision of the practice of midwives under rules approved by the General Medical Council and for the exercise of discipline amongst those who are enrolled upon the Register.

See Reports of Select Committee on Midwives Registration, together with the proceedings of the Committee. Minutes of Evidence, Appendix, and Index, ordered by the House of Commons to be printed June 17th, 1892, and Aug. 8th, 1893.

Be it enacted by the Queen's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:—

1. This Act may for all purposes be cited as the Midwives Registration Act, 1897.

2. In this Act—

The term "midwife" means a woman who undertakes to attend cases of labour in accordance with the regulations to be laid down under this Act.

"Midwives register" means a register of midwives kept in pursuance of this Act.

"Midwives Board" means the Board constituted under this Act for the purpose of carrying out the provisions of this Act.

3.—(1) From and after the *first day of January one thousand eight hundred and ninety* —— no woman shall be entitled to take or use the name or title of midwife (either alone or in combination with any other word or words), or any name, title, addition, or description implying that she is registered under this Act, or is specially qualified to act as a midwife unless she be registered under this Act.

(2) Any person who, after the *first day of January, one thousand eight hundred and ninety*——, not being registered under this Act, shall take or use the name of midwife or any other such name, title, addition, or description as aforesaid, shall be liable on summary conviction to a fine not exceeding *five pounds*.

(3) No woman shall be placed on the midwives register until she shall have complied with the rules and regulations to be laid down in pursuance of the terms of this Act.

(4) The certificate of registration under this Act shall not confer upon any woman any right or title to be registered under the Medical Acts in respect of such certificate, or to assume any name, title, or designation implying that she is by law recognised as a licentiate or practitioner in medicine or surgery, or that she is qualified to grant any medical certificate or any certificate of the cause of death.

4. Any woman who, before the expiration of *two years* from the passing of this Act, claims to be registered under this Act shall be so registered provided she produces evidence satisfactory to the Midwives

Hosted by Google

Board that at the *passing of this Act* she has either been in *bonâ-fide* practice as a midwife for a period of *two years*, or holds a certificate in midwifery from the Royal College of Physicians of Ireland or from the Obstetrical Society of London, or such other certificate as may be approved by the Board.

5. On the *passing of this Act* a Midwives Board shall be constituted by the General Medical Council and shall consist—

(1) of twelve registered medical practitioners, three to be appointed by the Royal College of Physicians of London, three by the Royal College of Surgeons of England, three by the Society of Apothecaries, and three by the Incorporated Midwives Institute; and

(2) of six persons to be appointed for terms of *three years* by the Lord President of the Council.

One-third of the elected members of the Board shall annually retire, but shall be eligible for re-election after the lapse of one year. The duties of the Midwives Board shall be as follow:

(*a*) To make rules for regulating the conditions of admission to the register and the mode of conducting the qualifying examinations.

(*b*) To appoint examiners.

(*c*) To decide upon the places where, and the times when, examinations shall be held.

(*d*) To frame for approval by the General Medical Council rules regulating the admission to the register of women already in bonâ fide practice as midwives at the passing of this Act.

(*e*) To prepare and publish annually a register of midwives.

(*f*) To frame for approval by the General Medical Council rules for regulating, supervising, and restricting within due limits the practice of midwives.

(*g*) To decide upon the conditions under which a midwife may be suspended from practice.

(*h*) To decide upon the removal from the register of the name of any midwife for disobeying the rules and regulations from time to time laid down under this Act by the Midwives Board or for other misconduct and to decide upon the restoration to the register of the name of any midwife so removed.

(*i*) And, generally, to do, subject to the approval of the General Medical Council, any other duty which may be necessary for the due and proper carrying out of the provisions of this Act.

6. There shall be payable by every woman presenting herself for examination or registration such fees as the Midwives Board may, with the approval of the General Medical Council, from time to time determine. All fees paid by midwives or by candidates for examination shall be paid to the Midwives Board. The said board shall devote such fees to the payment of expenses connected with examination and registration and to the general expenses of the Board. Should these fees not equal the expenditure of the Midwives Board, the deficiency shall be supplied from the respective local county funds, in proportion to the number of registered midwives resident in the county.

7. The Midwives Board shall appoint a registrar who shall be charged with the custody of the register, and shall also act as secretary to the Board.

8. A copy of the midwives register for the time being shall be evidence in all courts that the women therein specified are registered according to the provisions of this Act; and the absence of the name of any woman from such copy shall be evidence, until the contrary be made to appear, that such woman is not registered according to the provisions of this Act. Provided always that in the case of any woman whose name does not appear in such copy a certificate under the hand of the registrar of the entry of the name of such woman on the register shall be evidence that such woman is registered under the provisions of this Act.

9. Every local sanitary authority throughout England and Wales shall, on the *passing of this Act*, appoint its medical officer of health, or other registered medical practitioner or practitioners, as the local supervising authority over midwives in the sanitary district. It shall be the duty of the local supervising authority—

1. To exercise general supervision over all midwives practising within the sanitary district in accordance with the rules to be laid down under the provisions of this Act.
2. To investigate charges of malpractice, negligence, or misconduct on the part of any midwife practising within his district, and if he consider that a *primâ-facie* case is established to report the same to the Midwives Board.
3. To report at once to the Midwives Board the name of any midwife practising in his district convicted of a misdemeanour or felony.
4. To keep a current copy of the midwives register, accessible at all reasonable times for public inspection.
5. To satisfy himself, in the case of any midwife practising or desiring to practise within his district, as to the validity of her claim to be placed on the register.

10. The local supervising authority shall at once report to the Midwives Board the death of any midwife, or any change in the name or address of any midwife in his district, so that the necessary alteration may be made in the register.

11. Any woman who procures or attempts to procure herself to be placed on the register of midwives by making or producing, or causing to be made or produced, any false or fraudulent declaration, certificate, or representation, either in writing or otherwise, and any person assisting her therein, shall be deemed guilty of a misdemeanour, and shall on conviction thereof be liable to a fine not exceeding *five pounds*, or to be imprisoned with or without hard labour for any term not exceeding *two months*.

12. Any person appointed to keep the register of midwives wilfully making or causing to be made any falsification in any matter relating to the register of midwives shall be deemed guilty of a misdemeanour and shall be liable to a fine not exceeding *ten pounds*, or to be imprisoned with or without hard labour for any term not exceeding *three months*.

13. Any offences under this Act punishable on summary conviction may be prosecuted, and any fine under this Act recoverable on summary conviction may be recovered, in manner provided by the Summary Jurisdiction Acts.

The expenses of any prosecution shall be defrayed out of the county fund of the district where the prosecution takes place.

14.—(1) An appeal shall be allowed to the Privy Council should any disagreement arise between the General Medical Council and the Midwives Board respecting the carrying out of the provisions of the Act, or of any of them.

(2) Where any woman deems herself aggrieved by any order, conviction, judgment, or determination of or by any matter or thing done under this Act by any court of summary jurisdiction, such woman may appeal therefrom to the court of quarter sessions.

15. Nothing in this Act respecting midwives shall apply to legally qualified medical practitioners.

16. This Act shall not extend to Scotland or Ireland.

REPORT OF THE LYING-IN WARDS OF THE LIVERPOOL WORKHOUSE HOSPITAL FOR THE YEAR 1895 AND 1896; OR, WORKHOUSE MIDWIVES, THEIR TRAINING AND PRACTICE.

BY WILLIAM ALEXANDER, M.D. R.U.I., F.R.C.S. ENG.,
VISITING SURGEON, LIVERPOOL WORKHOUSE HOSPITAL.

TWO years ago, in consequence of what I still consider a grave mis-statement made before a Royal Commission, I published the results obtained in the lying-in wards of the Liverpool Workhouse Hospital for twenty-one years.[1] As the midwifery question is still before the profession and the public, and as the practice at this workhouse illustrates many points in dispute, the report for another period of two years, with remarks on the midwifery question from a disinterested observer, may be interesting to readers of THE LANCET.

The total number of confinements were 635. Of these women 221 were married and 414 were single, whilst 309 were primiparæ. A number of these patients, 289, were inmates of the workhouse for some time before being confined, and cleanliness, regular, simple diet, and regular hours were brought to bear upon them; 339 came direct from town in labour, and 7 came from the Lock wards, where they were under treatment for venereal diseases. The maternal deaths within the thirty-one days after confinement were three, and not one of these three had any puerperal trouble. One died from broncho-pneumonia, from which she had been suffering for four days prior to confinement, and she died four days after. A post-mortem examination showed normal pelvic organs and verified the chest disease. The second case was confined in the midst of a spree. She had a rigor the day before, her temperature was 102° F. during her confinement, and she was found to be suffering from acute pulmonary congestion. The labour was accomplished under imminent danger of suffocation, and in spite of medicine, inhalations, stimulants, &c., she died in twenty-four hours from the lung disease. The third case had been in the surgical wards for some time, with head symptoms that pointed to a cerebral tumour without localising it. She was stupid and inert, took her food only when it was given to her, but otherwise took no interest in anything around her. The baby was born, and the recovery proceeded naturally without any febrile symptoms. The condition of stupor gradually deepened, double incontinence and coma supervened, and she died nineteen days after delivery. We could not obtain a post-mortem examination. We have followed all the other cases until they left the workhouse or the thirty-one days of the Registrar-General were fulfilled, and certainly no other of the 635 cases died within that time. These 635 women gave birth to 646 babies—335 males and 311 females, twins eleven times. The presentations were: head, 623; breech, 11; hand, 2; foot, 8; face, 1; cord, 1. The operations consisted in 21 applications of forceps and 4 cases of version, and the complications consisted of 6 cases of hæmorrhage, 1 case of tumour of the brain, 1 of adherent placenta, 3 of retained placenta, and 57 where some increase of temperature took place after delivery.

The class of cases treated in this hospital belong to the lowest stratum of society, and the fact that 43 gave birth to hopelessly dead, and often decomposed, babies shows that neither their health nor their habits tended to uneventful and safe recoveries. The results are as satisfactory as they could possibly be from an obstetrical point of view, and while

[1] Liverpool Medico-Chirurgical Journal, July, 1894.

Hosted by Google

it is to be regretted that any deaths at all took place none of the deaths were preventible by any amount of obstetrical skill. How have these results been obtained? By a midwife, acting under the control of the medical staff and the lady superintendent of nurses. The present midwife was trained by us nearly twenty years ago, and she in turn helps to train a large number of midwives and monthly nurses every year. Our own nurses have three years' training in medical, surgical, and obstetric nursing, and three months of this period are devoted to obstetric work. They see fifty or sixty labours and conduct personally a dozen or more themselves, so that they leave well qualified to manage a midwifery case in the ordinary "midwife" way. Besides our own nurses we train a large number of nurses for institutions. These come for one year and have only one month in the lying-in wards. They become very useful as monthly nurses as they also are allowed to conduct a few cases, so that they know the practical work and would not be at a loss in any emergency until help arrived.

Nurses that have had eleven months' training in medical and surgical work, and much more those that have had two years and nine months of that work, are far more susceptible of obstetric training than the widows and other lone women who have been crushed out somehow into the cold and have taken to lying-in work as a means of livelihood. At one time we trained a few of these, but the response to the training on their part was very faint, and when their three months had elapsed they were just beginning to have a glimmering of the meaning of our teaching. Just as dentists have some training in common with medical men, I think obstetric nurses or midwives should have a training in general nursing, as they will then not only be more efficient midwives, but will have a choice of kinds of nursing from which to select according to their inclinations and opportunities.

The example of this institution and of other parochial and voluntary maternity charities throughout the country show that the successful and safe attendance of lying-in women presents no practical difficulties. We must have trained obstetric nurses, or midwives, and to be known to the public and recognised by the profession they must be registered. The second desideratum is medical supervision. I do not think the above-mentioned good results would be obtained at the Liverpool Workhouse by the midwife and her nurses if there were not only medical men to *help* them, but to *watch* them and their cases. Any patient showing febrile symptoms beyond that of the most ephemeral kind is removed at once from the lying-in ward, and if two or three cases become feverish one after another, not only are the wards emptied and purified, but the nurses are turned out for a day's holiday and for disinfection. The nurses attend all natural labours without interference, and although the medical staff visit the wards daily they probably never even speak to two-thirds of the inmates who are confined there. As to defining a natural labour we never meet with any difficulty because we never attempt such a silly task. We content ourselves with defining *unnatural labours*, as those where a nurse or midwife has to send for a medical man, and there is no difficulty at all either with us or the nurses in the matter. Hence no midwife should be allowed to practise for gain unless she is trained so as to know at once when a labour becomes unnatural, and because many labours are, or may become, unnatural their practice must be supported and supervised by a medical man appointed for the purpose. The jealousy of the trained and registered midwife that prompts present medical opposition to a safe, practical method of attending the parturient poor is as unreasonable as it has been illogically fomented by agitation.

Both medical men and midwives have their places, and the further we go down amongst the poor the more does the midwife become necessary and the less the medical man is required. The poor women are stronger, their labours are more natural, and less frequently require skilled assistance; but their surroundings are disagreeable and dangerous, and a trained midwife can dispel the disagreeable and dangerous conditions in a way that unskilled women could not do, and in face of which a medical man alone would be helpless. Whilst the lying-in wards of the workhouse hospital could not get on safely for long without the medical staff, I am afraid the medical staff would soon get into difficulties without the midwife and her staff. The one is a complement of the other, and the trouble that vexes and irritates unthinking medical men at the present time is the uncontrolled and untrained midwifery that exists and which should be remedied. By training and control women will have their fair and natural share of, and emoluments from, midwifery work, whilst medical men will occupy a more manly and dignified position in regard to labours amongst the poor than by the drudgery necessitated by personally attending badly paid confinements, where the wear-and-tear, anxiety, and exposure often lead to premature old age, and where the necessity of quickly terminating a case sometimes leads to dangerous or fatal measures being adopted, that the patience and leisure of the midwife would avoid. When medical men recognise that midwives (or whatever the same persons may in future be called) are their helpers and not their opponents a suitable method can soon be devised of training, registering, and allocating to the latter their suitable duties.

BUBONIC PLAGUE IN INDIA.

WE may say, as it does not appear to be generally known, that Indian medical literature contains a good deal of information regarding past outbreaks of Indian plague from time to time in various parts of that country, described for example, as Pali Plague, Mahamurree. Its first appearance of which there is any full record was in the Provinces of Kutch and Kattywar in the Bombay Presidency in May, 1815. In 1836 there was an extensive and virulent outbreak in Pali, Malwa, and other places, also in Gurhwal, and again in 1852 and 1876 in Gurhwal. The description of the symptoms leaves but little doubt as to the nature of the disease; and it is curious that reference is made in some of these descriptions to the mortality among rats—as in the case of Yunnan in Western China and elsewhere—that was early noticed in the present outbreak of the plague.

There was a very interesting discussion raised by Lord Reay in the House of Lords on Monday last on the subject. The Earl of Onslow, in replying to Lord Reay, quoted the contents of a telegram giving the latest official information concerning the progress of plague. According to this telegram the deaths from all causes in Bombay city for the week ending Feb. 12th were 1835; the deaths returned from plague were 813. Plague had been to some extent checked where first prevalent. Mandvi was now almost free from disease, but the general tendency of plague to extend northwards in Bombay city continued. In Poona there had been an increase from 43 to 47 cases during the week, but the disease was concentrated in certain quarters and so far showed no tendency to spread. One indigenous case had occurred in Poona cantonment. In Karachi there had been 269 cases during the week ending Feb. 12th and no indigenous cases in Sind outside Karachi. The disease was present—chiefly in a sporadic form—at a few other places in India. Calcutta, so far as is known at present, is free from the disease. It is satisfactory to find that the greatest precautions have been taken in all directions, and the amount of energetic work that has been performed in Bombay and elsewhere is remarkable. House-to-house visitation has been established, camps for the accommodation of the population have been opened in various directions, houses have been vacated and demolished or destroyed by fire—as many as thirty-five have been so destroyed in Bombay during the past week—and, in short, everything was being, or had already been, done that appeared necessary or desirable. Extensive powers are given to all district officers under the Epidemic Diseases Act, and the possibilities of extension of the disease to new localities are vigilantly watched.

We may refer our readers, or such of them as have not already perused any account of the discussion in the House of Lords, to the daily papers of the 16th inst. for a full report of what had been done with reference to measures of protective inoculation against bubonic plague. Both Lord Reay and the Earl of Onslow entered very fully into the experimental investigations of Dr. Yersin at Hong-Kong and other parts of China, the further experiments at the Pasteur Institute of France, the valuable remarks of M. Roux, and the researches of Professor Haffkine in India in regard to the discovery and use of a prophylactic serum and the number of inoculations that had already taken place with it in Bombay.

The latest telegram from Bombay (Feb. 10th) states that

Hosted by Google

since the outbreak of plague in that city there had been 5960 cases and 4581 deaths.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.

THE annual general meeting of this society was held at the offices, 12, New-court, Carey-street, Lincoln's-inn, on Tuesday last, Feb. 16th, Dr. Heron (the treasurer) being in the chair.

In recommending the adoption of the fourth annual report and balance-sheet for the year ending Sept. 31st, 1896, Dr. Heron said the past year had been a very quiet one for the society and they had had fortunately no serious expenditure to meet. He then went over the items in the statement of accounts, and *à propos* of the legal expenditure remarked that the society owed a debt of gratitude to their solicitors for the skilful way in which these gentlemen had piloted the society through various cases, some of which might have resulted in considerable expense. He pointed out how four years ago the society started with empty coffers with the help of a very few men interested in medical defence, and that at the close of last year they had a balance of unexpended income amounting to £382. The guarantee fund, which was a fund that could be made available in the event of dire emergency and would be only used in such a case, amounted to £1700, and that, added to the balance of income, made a total of over £2000 available for the purposes of the society. This, he thought, was a very satisfactory state of affairs. The council of the society had determined to place some of this surplus money under trust, and Sir William Broadbent and Mr. T. Pickering Pick had kindly consented to act as trustees of the reserve fund. This fund would be started with the purchase of £300 worth of 4 per cent. New Zealand Stock, which would cost the society at its present market value a little over £340. The fund could only be used to meet some exceptional demands upon the funds of the society on the recommendation of the council and with the consent of the trustees. The ordinary income of the society, he stated, was now more than enough to meet the ordinary expenditure.

On the motion of Mr. Spencer Watson the report and balance-sheet were unanimously adopted.

On the motion of the chairman, Mr. Jonathan Hutchinson was re-elected President of the society. Dr. Heron said that one of the most valuable assets of the society was the fact that Mr. Hutchinson's name appeared on the list of the society's officers as its president, for wherever medical literature was studied the name of Jonathan Hutchinson was respected.

The vice-presidents were re-elected, as were also the members of the council, with the following alterations. In the place of the late Mr. James Savage, Sir Hugh Beevor; and in the place of Mr. H. C. C. Shaw, who retires owing to ill-health, Dr. Major Greenwood. Dr. Heron was re-elected treasurer.

In moving the re-election of Dr. Hugh Woods and Mr. A. G. R. Foulerton, the honorary secretaries of the society, the chairman pointed out that these two gentlemen had given a great deal of time and had worked very hard in the service of the society, but that they had hitherto received no substantial remuneration from the society. He thought the medical profession ought to set its face against the vast amount of unpaid work that was done in connexion with it, and that as the affairs of this society were now in a fairly prosperous condition the time was near at hand when not an adequate remuneration, because that the society could not afford, but a substantial remuneration ought to be paid to the secretaries. This, he desired to say, was purely his own personal opinion, made entirely upon his own responsibility, and was in no sense official.

The two honorary secretaries were then unanimously elected, and after a resolution had been passed recommending that each division of the society should hold an annual meeting and furnish a list of the officers elected at that meeting, and an account of any matters that come under their consideration, the meeting closed with a hearty vote of thanks to the chairman.

THE RUSSIAN CONFERENCE ON SYPHILIS AND VENEREAL DISEASES.

THE Conference on the subject of Syphilis and other Venereal Diseases for which preparations have been carried on for over a twelvemonth was held recently in St. Petersburg. The Conference was organised very much on the same lines as that which met in the same city in the winter of 1892 to deal with the subject of cholera. That is to say, the Government had invited representatives from local authorities throughout the empire, and in addition a large number of experts in the subject under discussion and representatives of universities, hospitals, and other scientific institutions were requested to join in the deliberations of the Conference. The meetings were held in the Medical Department of the Ministry of the Interior and were under the presidency of Dr. Ragozin, the Director of that department. The Conference was opened on Jan. 15th (27th), and morning and evening meetings were held daily until the close of the Conference on Jan. 22nd (Feb. 3rd). The total number of members was considerably over 400.

The opening speech was made by the Minister of the Interior, M. Goremuikin, who stated that his predecessor, M. Durnovo, had taken the first steps towards organising such a congress as long ago as March, 1895. During the interval the Government had been actively collecting statistics and information on the subject of the spread of syphilis in Russia, and their request to the local authorities to coöperate in the matter had led to the collection of a vast quantity of material, which would form the basis of the present discussions. Speeches were also made by Dr Ragozin and Professor Tarnovski. The former stated that the object of the Conference was less to discuss the scientific aspect of venereal diseases than to form a plan of action based on scientific conclusions which should lead to practical results in diminishing the spread of such diseases. Professor Tarnovski briefly reviewed the steps taken in the past by the Government in this direction.

At the subsequent discussions an immense number of resolutions were discussed and carried. As there were over 300 such resolutions it is clear that only a small portion of them can be mentioned in the present report. One large group of conclusions, 17 in number, deal with the prevention of venereal disease in factories and mines and among artisans generally.

Briefly, these resolutions declare the necessity for increased medical and hygienic control over artisans. As their inspection with the avowed object of discovering venereal disease would be likely to meet with opposition it is proposed that a general medical inspection should be made compulsory, that this should be carried out on all new hands engaged in a factory or mine, that it be repeated after every holiday or absence for any length of time, and perhaps, if possible, it might be made periodic at fixed intervals. It is further proposed that hospital treatment be made compulsory, at least during the infectious period, whenever venereal disease appears in an artisan, and that the family of the infected person should be persuaded, by all efforts in the medical officer's power, to submit to inspection. The other resolutions of this group deal with the necessity for the medical and hygienic supervision of fairs and markets, of public baths, workmen's barracks, and similar public institutions.

Papers on the Prevention of Venereal Diseases in the Army and Navy were read by Dr. Sholkofski and Dr. Sukhof. The most important resolutions on the subject were the following. Local conditions and the nature of the service a particular regiment is on appear to be the determining factors in the prevalence of syphilis in the army. The present regulations are well adapted to keep the disease in control, but a few alterations are suggested. Among these is the proposal that in ports and places where troops are stationed the naval or military surgeon should be a constant member of the local medical board, in order that he may have a voice in the general measures for controlling venereal diseases in the district. Medical inspection of the men should be every three weeks instead of every four; special measures should be taken with the individual infected with syphilis, not only while he is in the service, but after he returns home; entertainments, debates, concerts, and so

Hosted by Google

forth should be more frequent, to provide the men with a counter attraction to the drinking house and brothel. The proposal of the organising committee of the conference, that men who contract syphilis should be compulsorily detained in the services for two years from the date of infection, was unconditionally vetoed by the members of the conference. Special measures are suggested for the control of syphilis among sailors in foreign waters. Among these may be mentioned the proposal that the daily distribution of *vodka* (a Russian spirit distilled from rye) on board ship should be done away with, some slight improvement in the food being substituted for it; and that, further, the serving out of *vodka* as a reward for special services should be done away with.

A special section of the Congress, under the presidency of Professor Kapustin of the University of Kazan, was devoted to the subject of Syphilis in Villages. Twenty-one resolutions embody the conclusions of the conference on this subject. It recognises that the great difficulty in the battle with venereal diseases in the villages lies in the ignorance and low state of culture of the peasantry. It urges the necessity for increased education, and as a special measure proposes the holding of popular lectures by medical men on health questions. In Russian villages venereal diseases are more usually spread by extra-sexual methods than by sexual, and this is the direct result of the ignorance of the peasants in all hygienic matters. All measures to deal with the evil must be such as involve no compulsion. Inspection of every individual is not recommended, but there should be facilities for it if the peasants are willing. Moving bodies of peasants (such as pilgrims, emigrants, and men seeking work) should be able to get free medical aid in all central towns they may pass through, and on railways and steamers. At present the best means of supervising bodies of workmen seeking work in distant parts of the country is, in the opinion of the Congress, not quite clear; but it is extremely undesirable to institute a system of health certificates on giving the labourer his travelling passport or on his return to the village. The reasons which led the conference to formulate this resolution are not as yet published; they will be read with interest when the final report of the conference is issued.

The spread of venereal disease in the village is undoubtedly increased by the return of conscripts from the army and also by the encamping of troops in or near the village; special measures are therefore suggested to deal with this risk, particularly in the way of supervising the men, both while in the service and after they have left it. All temporary measures, such as the sending of "flying squadrons" of medical men and nurses, such as have for some years past been sent through the country to treat eye diseases, are declared to be undesirable in the case of venereal diseases; but in many places when local means are inadequate the Government might provide assistance in various ways. The provision of crèches for children, and the supervision of school children suffering from syphilis are other measures recommended by the conference. A word of warning is uttered as to the need for care in vaccinating infants and adults. It was resolved that the conclusions of the conference in this section be sent to the local authorities throughout the country.

A group of nineteen resolutions deal with the prevention of Syphilis in Towns. They scarcely require individual mention here; they are based on the general principles of instructing the people and providing facilities for treatment. They touch upon the subject of prostitution, but only incidentally, as for this a separate group of resolutions was reserved. An able paper on this subject, and one which led to prolonged discussions, was read by Dr. Sturmer. The conclusions of the conference were to the effect that prostitution is an ineradicable evil. There are practically two classes of prostitutes, the registered and the secret or unacknowledged prostitute. The latter is the most dangerous factor in the spread of venereal diseases. As harsh compulsory measures only defeat their own end it is recommended that the system now in practice in some places should be introduced into all towns. This system combines a secret control of unacknowledged prostitutes with an open control of acknowledged ones. The former have no police tickets nor is their name even known to the police. Other special measures provide for the severe punishment of people who make money by the prostitution of their own wives, daughters, or other relatives, and wards, and for the special protection of all young girls under sixteen. Resolutions also deal fully with the registration of "ticketed" prostitutes, provision for their supervision and free hospital treatment, and a number of other matters in this connexion.

The final meeting of the conference took place on Jan. 22nd (Feb. 3rd). Dr. Ragozin thanked all the members of the Conference for their untiring attendance, which had enabled them to get through an almost unprecedented amount of labour, and which he hoped would lead to valuable practical results. Other speeches were made by Professor Ghé and Professor Kapustin of Kazan and Professor Tarnovski. Votes of thanks followed to the President and others, and Dr. Ragozin declared the Conference closed. In the evening a complimentary dinner was given to Dr. Ragozin by the members of the Conference.

It is too early yet to form a final opinion as to the value of the work done by the Conference. When the full report of the discussions is issued it will probably contain a great quantity of valuable material relating to the prevalence of venereal diseases in Russia and the methods now in practice for dealing with them. The resolutions proposing fresh measures appear to fall into two groups—those which can at once lead to action and those which will require legislation before action can follow. As most of the members of the Congress were members of the local governing authorities of the district they represented the first-named group of resolutions may be expected to at once lead to results; and, judging by the precedent of the Cholera Conference in 1892, it is exceedingly probable that fresh legislation may be anticipated in the near future in accordance with the conclusions of the recent Conference.

THE LONDON WATER QUESTION.

THE adjourned discussion on Mr. W. J. Dibdin's paper on the Character of the London Water-supply (see THE LANCET, Jan. 23rd, p. 269) was continued at the meeting of the Society of Chemical Industry on the 15th inst.

Mr. BLOUNT re-opened the discussion by congratulating Mr. Dibdin on his method of using the micro-filter. It was a drawback, however, that assumptions had to be made on account of the diameter of the measuring-tube of the micro-filter not being readily known, and he desired to know whether it was not possible to obtain these tubes ready standardised. He suggested that the inevitable "rust and dust" might be due to the wearing of the packing in the joints, and considered that there was not sufficient difference between the "inevitable" suspended matter and the total actually found to cause alarm. He objected to the softening of the water.

Mr. GRANT HOOPER deprecated the method of stating the suspended matter as tons per annum. The quantity was really very small, being only $\frac{1}{10\,0}$th of a grain per gallon. He wished to know how Mr. Dibdin concluded that 30 per cent. of the samples were objectionable. He thought the Kent Company's water was recognised as a standard of purity, but 18 per cent. of the samples of this water were set down as objectionable. He approved of softening the water, but the cost, which had been declared by the Royal Commission of 1851 to be 27*s.* per million gallons, equalling 10 per cent. of the cost of obtaining the water, seemed prohibitive.

Mr. WM. THORP repeated some of his former criticisms, and specially objected to Mr. Dibdin's way of stating the deposit in tons, as an attempt to make analytical results understandable by laymen (Mr. DIBDIN: Quite so.). He thought it was a similar case to a physician explaining symptoms in a popular manner to a lay audience.

Another gentleman called attention to a method for softening and sterilising potable water reported on favourably by THE LANCET.

Mr. E. J. BEVAN pointed to some inconsistencies between the amount of deposit on the micro-filter and the gravimetric determinations. He thought that the concordance between the physical, chemical, microscopical, and biological results was by no means so striking as Mr. Dibdin made out, and called attention to discrepancies between some of the figures for the nitrogen in the suspended matter and the oxygen absorbed. He considered Mr. Dibdin's paper a splendid—indeed, monumental—piece of work.

Mr. WHITTAKER thought that, on the whole, the water companies had done their best with the supply they were able to obtain. At the same time there were risks, and it would be a great advantage if water could be supplied from a source that did not require constant watching. He spoke

Hosted by Google

very highly of the softening appliances in use at Southampton. The water dealt with resembles the Kent water and is reduced to six or eight degrees of hardness at a cost of ¼*d*. per 1000 gallons.

Dr. BERNARD DYER admired Mr. Dibdin's micro-filter methods. He regretted that the sample of water had been taken from the mains instead of from the outlets of the filter beds. The consequence was that the results given in Mr. Dibdin's paper and the London County Council report were not comparable with those of the chemists retained by the companies. Dr. Dyer said that what they wanted to find out was whether the water left the filter beds in good condition. It was possible that the large number of organisms found by Mr. Dibdin might be due to multiplication of the few that had escaped the filter beds, and the suspended matter in certain cases might result from the breaking away of the slimy covering of the inside of the pipes.

Mr. GROVES asked questions as to the method of collection of the samples. The amount of suspended matter was of little consequence; it was the nature of the bacteria that was important. The water should have been examined on leaving the filter-beds, as the interior of the pipes was anything but immaculate. He suggested that a large reservoir should be formed higher up the Thames to receive flood-water. This would allow time for the deposit to settle and a small proportion of brine might be added to assist in the destruction of the bacteria.

Dr. RIDEAL considered that the amount of oxygen absorbed was the best means of differentiating between good and bad waters. He had to examine the Kent, Southwark, and Lambeth Companies' waters in his district and found that the waters derived from the Thames absorbed about ten times as much as the Kent Company's water. He considered it most important that the nature of the organisms should be determined by cultivation on agar-agar at blood-heat. There was a marked difference between the colonies yielded by the Thames and Kent water when treated in this manner. All the organisms present in the latter were frequently killed entirely, whilst those from the Thames and Lea waters multiplied at blood heat. He thought that a water should not be considered safe unless 95 per cent. of the nitrogen was present as nitrate.

Dr. MOTT thought that the similarity between the deposit from the filtered and unfiltered water was very serious. The quality of the bacteria present was important and not the quantity. Typhoid infection always came from sewage, and it was essential that the organisms should be stopped by the filter beds. He considered that the proper cleansing of the pipes and cisterns inside the houses was quite as important as attention to the water-supply itself. In Vienna the houses had been thoroughly overhauled when the new water-supply was introduced, and there had been a great decrease in epidemics. He thought that soft water was preferable to hard, especially for gouty people, although hard water was generally purer. In conclusion Dr. Mott highly commended the suggestion of Dr. Rideal that cultivations should be made on agar-agar at blood temperature, and pointed out that Dr. Klein had found considerable quantities of the bacillus coli communis in London water.

In reply Mr. DIBDIN said that he could not find any confirmation of Mr. Burgess's theory that the deposit varied according to the length of main traversed. His early microscopic work showed that large quantities of débris were present, and then quantitative estimations were substituted. As soon as this became known there was a marked and rapid falling off in the quantity of suspended matter. The results from the Welsh rivers were put in for the sake of comparison; five or six samples were taken and they were given for what they were worth. He thought that the softening of London waters was most desirable on the grounds of health, comfort, and economy, and quoted the old saying that lime costs 14*s*. and soap £20 per ton. If London water were softened the difference between Welsh and London water after softening would be *nil*. Although this militated against the contentions of a certain party, he thought that a scientific report should contain the whole truth. Referring to the reports of the analysts to the water companies Mr. Dibdin said that for many years the reports, contained the stereotyped formula, "a few moving organisms," which was subsequently changed to "bacteria." Not a word was said about suspended matter. The strength of a chain was that of its weakest link, and the quality of a water should be judged from the worst results obtained from it and not from the average. Dr. Percy Frankland had stated that the bacteria were in close relation to the suspended matter, yet the reports of the water analysts ignored it, but gave the quantities of carbon and nitrogen, which might be derived from peat, to the third place of decimals. On account of this the companies themselves were not aware of their danger. He had a high opinion of the companies. Far from having a quarrel with them, he thought they did their work well, and when they knew of a danger did their best to cope with it. The examination of the deposit under the microscope was most startling, as great lumps of decaying organic matter, resembling flue from the floor, could be seen. He defended the method of stating deposit in tons as carrying conviction to the lay mind that it existed, whereas decimals would have been pooh-poohed. There was no necessity for standardising the micro-filters. As regards the correction for "rust and dust," of which much had been made, he merely assumed in fairness to the companies that this was unavoidable. He was far from being convinced that it was so—in fact, since the report the minimum had diminished. He considered there was no danger to be apprehended from the water-supply so long as the companies worked as well as they were doing now. But there was always a danger of laxity. If the London County Council should in future be the water authority it should have a Local Government Board inspector to keep it up to the mark. In conclusion, he thought that the water from the main gave the average result of the working of all the filter beds. If taken individually nine filter beds might be doing well, whilst one which might be overlooked might have broken down. In addition, there was no check against the filter beds being by-passed altogether. In taking samples from the standpipes the microscopic results were checked by gelatin cultures inoculated on the spot and the two were found to agree perfectly.

A hearty vote of thanks was accorded to Mr. Dibdin for his paper.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 7454 births and 4128 deaths were registered during the week ending Feb. 13th. The annual rate of mortality in these towns, which had increased in the three preceding weeks from 19·2 to 20·8 per 1000, declined again last week to 19·6. In London the rate was 18·6 per 1000, while it averaged 20·3 in the thirty-two provincial towns. The lowest rates in these towns were 12·5 in Croydon, 12·6 in Cardiff, 13·4 in Gateshead, and 14·2 in Halifax; the highest rates were 23·9 in Manchester, 24·2 in Huddersfield, 25·5 in Liverpool, and 26·2 in Plymouth. The 4128 deaths included 337 which were referred to the principal zymotic diseases, against 367 and 361 in the two preceding weeks; of these, 108 resulted from whooping-cough, 62 from diphtheria, 52 from measles, 49 from diarrhœa, 35 from scarlet fever, 29 from "fever" (principally enteric), and 2 from small-pox. No death from any of these diseases was recorded either in Norwich or in Gateshead; in the other towns they caused the lowest death-rates in Plymouth, Derby, and Huddersfield, and the highest rates in Nottingham, Salford, Bolton, and Oldham. The greatest mortality from measles occurred in Oldham and in Bolton; and from whooping-cough in Swansea, Bristol, Nottingham, and Burnley. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 62 deaths from diphtheria included 37 in London, 4 in Birmingham, and 4 in Liverpool. Two fatal cases of small-pox were registered in London, but not one in any other of the thirty-three large towns. There were 38 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 13th inst., against 2, 9, and 21 at the end of the three preceding weeks; 20 new cases were admitted during the week, against 7 and 12 in the two preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3050, against 3354, 3311, and 3153 on the three preceding Saturdays; 226 new cases were admitted during the week, against 249, 254, and 245 in the three preceding weeks. The deaths referred to diseases

Hosted by Google

of the respiratory organs in London, which had been 355 and 404 in the two preceding weeks, declined again last week to 373, and were 93 below the corrected average. The causes of 72, or 1·7 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Nottingham, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Cardiff, Liverpool, Birmingham, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·3 and 26·6 per 1000 in the two preceding weeks, further rose to 28·8 during the week ending Feb. 13th, and exceeded by 9·2 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 21·4 in Leith and 21·5 in Aberdeen, to 33·3 in Glasgow and 40·9 in Perth. The 857 deaths in these towns included 105 which were referred to the principal zymotic diseases, against 81 and 96 in the two preceding weeks; of these, 39 resulted from whooping-cough, 31 from measles, 19 from diarrhœa, 7 from "fever," 5 from scarlet fever, and 4 from diphtheria. These 105 deaths were equal to an annual rate of 3·6 per 1000, which was 2·0 above the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had increased in the three preceding weeks from 26 to 32, further rose last week to 39, of which 27 occurred in Glasgow, 8 in Edinburgh, and 3 in Perth. The deaths from measles, which had been 28 in each of the two preceding weeks, rose to 31 last week, of which 23 were recorded in Glasgow, 4 in Edinburgh, and 3 in Aberdeen. The 7 deaths referred to different forms of "fever" exceeded by 3 the number in the preceding week, and included 4 in Glasgow. The fatal cases of scarlet fever, which had been 5 and 7 in the two preceding weeks, declined again to 5 last week. The 4 deaths from diphtheria were within one of the number recorded in the preceding week, and included 3 in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 190 and 229 in the two preceding weeks, further rose to 240 last week, and exceeded by as many as 134 the number in the corresponding period of last year. The causes of 51, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 42·4 and 44·2 per 1000 in the two preceding weeks, declined again to 41·2 during the week ending Feb. 13th. During the past six weeks of the current quarter the death-rate in the city has averaged 40·3 per 1000, the rate during the same period being 19·0 in London and 22·5 in Edinburgh. The 276 deaths registered in Dublin during the week under notice showed a decline of 20 from the number in the preceding week, and included 58 which were referred to the principal zymotic diseases, against 46 and 52 in the two preceding weeks; of these, 26 resulted from measles, 25 from whooping-cough, 3 from "fever," 2 from scarlet fever, 1 from diarrhœa, and 1 from small-pox. These 58 deaths were equal to an annual rate of 8·7 per 1000, the zymotic death-rate during the same period being 1·6 in London and 2·7 in Edinburgh. The fatal cases of measles, which had been 7 and 18 in the two preceding weeks, further rose to 26 last week. The deaths from measles, which had been 27 and 24 in the two preceding weeks, were 25 last week. The 3 deaths referred to "fever" slightly exceeded those recorded in the two preceding weeks, while the 2 fatal cases of scarlet fever showed a further decline from recent weekly numbers. The 276 deaths in Dublin last week included 43 of infants under one year of age, and 62 of persons aged upwards of sixty years; the deaths of infants showed a marked decline, while those of elderly persons slightly exceeded the number in the preceding week. Six inquest cases and 6 deaths from violence were registered; and 77, or more than a fourth, of the deaths occurred in public institutions. The causes of 17, or more than 6 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ARMY MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL W. H. STEELE is about to retire. Surgeon-Major Hunter has been ordered to the Cork District for duty, and Surgeon-Captain A. W. Bewley has been ordered to join at Dublin. Surgeon-Colonel J. P. Rooney has been appointed P.M.O., Scottish District. Surgeon-Major A. H. Burlton will shortly assume medical charge at Dover. Surgeon-Major B. T. McCreery has assumed charge of the troops at Newry. Surgeon-Major E. Butt has proceeded from Newry to Dundalk. Surgeon-Major J. M. Irwin has assumed medical charge of the Station Hospital at Brighton. Surgeon-Major G. H. Sylvester has assumed medical charge of women and children, Stanhope Lines, Aldershot.

The under-mentioned Surgeon-Majors to be Surgeon-Lieutenant-Colonels:—Michael R. Ryan, M.D., Edward O. Reynolds, Henry J. Robbins, M.D., John J. Morris, M.D., Aylmer E. Hayes, D.S.O., John F. Williamson, M.B., John T. Carey, M.B., William J. R. Rainsford, F.R.C.S. Irel., Isaac Boulger, Thomas Boyd, Percy H. Johnston, M.D., Isaac B. Emerson, Eugenius A. Roche, Ulick J. Bourke, Joseph J. Lamprey, William H. Allen, Jones L. Peyton, M.B., Arthur W. Carleton, M.B., F.R.C.S. Irel., George A. Hughes, M.B., Brisbane W. Somerville-Large, F.R.C.S. Edin., Phineas B. Tuthill, M.D., F.R.C.S. Irel., and John P. Hunt, M.D., F.R.C.S. Irel. Surgeon-Captain James R. Forrest to be Surgeon-Major. The under-mentioned Surgeons on probation to be Surgeon-Lieutenants:—George Elliott Frank Stammers, Charles Frederick Wanhill, Wilfrid Edward Hudleston, Martin Percy Corkery, Frederick John Gaine, Leonard Adams Williams, Ernest William Bliss, Malcom MacGregor Rattray, M.B., John Henry Power, Richard Edward Game Phillips, Thomas Henry Matthews Clarke, M.B., and Edwin Walter P. V. Marriott.—*London Gazette.*

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain Parry, A.M.S., on return from leave in England, has been posted to general duty, Aden District. Surgeon-Lieutenant Walker, A.M.S., on arrival from England, has been posted to general duty, Quetta District. The services of the under-mentioned officers (Bengal) are placed temporarily at the disposal of the Government of the Punjab:—Surgeon-Captain R. Heard and Surgeon-Lieutenant C. J. Milne. Honorary Surgeon T. H. Hendley, C.I.E. (Brigade-Surgeon-Lieutenant-Colonel), has been appointed Surgeon-Lieutenant-Colonel of the Bombay, Baroda, and Central India Railway Volunteer Rifle Corps. Surgeon-Lieutenant John Muspratt Comley has been promoted Surgeon-Captain of the Cossipore Artillery Volunteers. The following promotion is made, subject to Her Majesty's approval:—*Bengal Establishment:* To be Brigade-Surgeon-Lieutenant-Colonel: Surgeon-Lieutenant-Colonel Charles Henry Joubert, M.B., vice Brigade-Surgeon-Lieutenant-Colonel G. Massy, retired.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Staff-Surgeon Alfred Page to the *Brisk.* Surgeons: Albert X. Lavertine to the *Pembroke,* additional, Robley H. J. Browne to R.N. Depôt, Walmer, and W. E. Marshall to the *Duke of Wellington.*

VOLUNTEER CORPS.

Rifle: 1st Volunteer Battalion the Royal Fusiliers (City of London Regiment): William Henry Russell Forsbrook, M.D., to be Surgeon-Lieutenant. 3rd Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant W. A. Renshaw resigns his commission. 2nd Volunteer Battalion the Royal Sussex Regiment: Honorary Assistant-Surgeon C. L. Evershed resigns his commission. 3rd (Dundee Highland) Volunteer Battalion the Black Watch (Royal Highlanders): William Edward Foggie, M.B., to be Surgeon-Lieutenant. 5th (Perthshire Highland) Volunteer Battalion the Black Watch (Royal Highlanders): Edward Ley Paton, M.B., to be Surgeon-Lieutenant.

THE VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the under-mentioned officers of the Volunteer Force:—*North-Eastern District:—Rifle:* 1st Volunteer Battalion the East Yorkshire Regiment: Surgeon-Lieutenant-Colonel Henry Thompson, retired. *Thames District:*

Hosted by Google

Artillery: 1st Kent Volunteer Artillery (Eastern Division, Royal Artillery): Surgeon-Lieutenant-Colonel Robert Ross Brown. *Home District: Rifle:* 3rd Middlesex Volunteer Rifle Corps: Surgeon-Lieutenant-Colonel Frederick Orton. 22nd Middlesex (Central London Rangers) Volunteer Rifle Corps: Surgeon-Major Robert Cuff, retired. 3rd London Volunteer Rifle Corps: Surgeon-Major George Hastings. *Scottish District: Rifle:* 3rd (Dumfries) Volunteer Battalion the King's Own Scottish Borderers: Surgeon-Lieutenant-Colonel Andrew Dall MacDonald, M.D.

THE HEALTH OF THE BRITISH ARMY IN INDIA.

We are glad to notice that this subject continues to attract attention and is not being lost sight of amid the variety of political and other topics of public interest at the present time. A communication from "Sanitas" in the *Times* of the 16th inst., in reply to one from Mr. Gregory, publishes some facts and figures derived from blue-books which put the question of contagious disease in a very different light to that represented by the opponents of all protective legislation. The figures show, says "Sanitas," that this class of disease rose in India from 371 per 1000 in 1888 to 482 in 1889 and 504 in 1890. "For the years 1889 and 1890 the Army was practically 'unprotected,' but towards the end of 1890 (Parliamentary Return No. 318 of 1895, page 29) new cantonment rules, affording a modified measure of 'protection,' came into force. In 1891 the admission-rate for these diseases fell to 401, and it was only 410 in 1892. In 1893 the new cantonment rules were condemned by a committee (Mr. G. Russell's) at home. The figures of 'contagious disease' for the years 1893, 1894, and 1895 have been 466, 511, and 537 per 1000. (For the last year see Army Medical Department Report for 1895.)."

MEASLES AT DEVONPORT.

Measles in a mild form has broken out on board the *Impregnable* training ship for boys at Devonport. The disease, which is very prevalent in the district, has attacked five boys in the ship, and they have been removed to the Naval Hospital.

Surgeon-Colonel J. Lane Notter, Professor of Hygiene in the Army Medical School, Netley, proceeds to Venice to attend the International Congress on the Plague.

The transport *Dunera* arrived at Southampton on the 12th inst. She brought home thirty-four invalids for the Royal Victoria Hospital, Netley.

Correspondence.

"Audi alteram partem."

SURGEON-CAPTAIN HEHIR AND THE PARASITE OF MALARIA.

To the Editors of THE LANCET.

SIRS,—In connexion with a long paper by Surgeon-Captain Hehir, given in THE LANCET of Nov. 28th and Dec. 5th, 1896, and entitled "The Hæmatozoon of Malaria and its Discovery in Water and Soil," I feel it my duty to make the following remarks. The paper in question implies not only that the writer has discovered a hæmatozoon in cholera and syphilis, but that he has found new forms of the parasite of malaria and has discovered its existence in water and soil. These discoveries have already been mooted by him in several papers—for example, one on Microscopical Observations on the Hæmatozoon of Malaria, published in 1891, and another on his Cholera Organism, published as a special supplement to the April number of the *Indian Medical Gazette*, 1892. In June, 1893, I called on Surgeon-Captain Hehir with two specimens of malarial blood and persuaded him to give me a demonstration of his malaria parasite. He showed me some examples of his small hyaline bodies; they were the exudation bubbles which escape from blood plates in blood kept for an hour or so. He showed me also examples of his hæmatomonas malariæ stellatum; they were ordinary stellate arrangements of fibrin such as are figured in some text-books of physiology. These facts were publicly referred to and Surgeon-Captain Hehir's conclusions challenged in a paper published by me in the *Indian Medical Gazette*, 1893, page 329; but Surgeon-Captain Hehir has then and since ignored my remarks, though in the same number of the *Gazette* there was an editorial inviting his attention to them. In the same periodical for January, 1894, I gave further a long paper describing various appearances produced by the "third element of the blood" (blood plates) and detailing some of the errors made by Surgeon-Captain Hehir, and in the December number of the same year, as well as in a paper read before the Budapest Conference held at the time, I furnished a list of "pseudo parasites" which had, I thought, deceived many observers, among them Surgeon-Captain Hehir and myself. But Surgeon-Captain Hehir has never that I know of thought fit to refer to any of these strictures. Now, with respect to the hæmatozoon of cholera. In Secunderabad in 1895 having some cases of cholera, I wrote and telegraphed to Surgeon-Captain Hehir inviting him to demonstrate his organism to me (since he was living a few miles away). He replied that he had not time to do so. I wrote again, pointing out that since Mr. Hankin had published a letter (*Indian Medical Gazette*, May, 1895) suggesting that one of Surgeon-Captain Hehir's forms "is nothing but crystals of common salt, others resemble kinds of precipitates, fragments of fibrin, and altered red or white corpuscles," it was incumbent on him to demonstrate his organism to some one, such as myself, familiar with the ordinary appearances of blood. To this letter I received no reply.

Surgeon-Captain Hehir is, of course, not obliged to instruct others; but personally I think that he should have felt himself bound to take a little trouble to demonstrate such very startling discoveries to anyone, even to a person like myself, whom he may have deemed not sufficiently well-informed to understand them. Since he did not do so he cannot complain if I give my opinion of his work very freely, and my opinion is briefly as follows. Surgeon-Captain Hehir's *brochures* on these hæmatozoa of his are so confused that it is almost impossible to understand what he means. For instance, in the article lately published in THE LANCET there are no less than 134 numbered paragraphs, which are generally jumbled together without sequence and in such a manner that paragraphs on staining are abruptly interposed between descriptive paragraphs, while references to future explanations which are never given, and to "larger bodies" and "smaller bodies" and "long and broad varieties" which are never described, leave the intellect of the reader in a state of collapse. At the same time the whole paper is full of learned terms and suggests difficulties of investigations so enormous that I fear no one will be able to confirm Surgeon-Captain Hehir's observations. Nowhere is a plain object plainly described; dimensions are not given; the numbers to be found in a field are not specified; and amount of movement is left indeterminate. Really, those interested in the parasite cannot accept this sort of thing.

When, however, by dint of hard application, we begin to resolve the nebulæ we find only that Surgeon-Captain Hehir still remains a victim of the blood-plate. He says (paragraph 104) that he has discovered "invisible forms of the parasite"; the masses of blood-plates are almost invisible. He says (paragraph 58): "In every instance the more developed the parasite the less distinct and the more transparent and invisible it is." "Where the hæmoglobin is largely dissolved in the plasmotic fluid it gives the appearance of the parasite having been stained." This is an excellent description of a cluster of blood-plates, which accordingly I take to be "in every instance" Surgeon-Captain Hehir's more developed parasites. Again (paragraph 78) he says: "There are also considerable numbers of ciliated spherical bodies, the cilia being long, firm, and pass (ing?) out at right angles abruptly, leaving spaces between each other, in which spaces arise a considerable number of varying sized cyst-like bodies which are set free and become the hyaline spherical body mentioned above." This is a correct description of a unique object which was described by me in "The Third Element of the Blood," being a cluster of invisible blood plates, or microcytes as I called them, surrounded by long filaments of fibrin (Surgeon-Captain Hehir's cilia) and giving rise to exudation bubbles (Surgeon-Captain Hehir's hyaline bodies) between the fibrin filaments. The description confirms Surgeon-Captain Hehir's demonstration to me of his hyaline bodies, which were the exudation bubbles aforesaid, and renders it unnecessary to criticise further his work (either on malaria, cholera, or syphilis). He has evidently mistaken for a parasite a very ordinary object, but one which is not

Hosted by Google

generally described in text-books on the blood. In a similar manner he has made mistake after mistake. Blood-plates, fibrin-filaments, clusters of blood-plates (paragraphs 77 to 81) are magnified by his imagination into spores, cilia and flagella, and chlamydospores respectively. Echinoid or hairy corpuscles, so well known, become flagellated red-corpuscles (paragraph 88). There are flagella like silk fibres (paragraph 85). Perinuclear granules of leucocytes have "a nucleus and nucleolus, develop flagella, free themselves, and wander about the field" (paragraph 97). Every part of a parasite, even the framework, is reproductive (paragraph 87). Red corpuscles pair off, fuse their nuclei, and commence sporulation (paragraphs 88 to 91). Flagella disintegrate into micrococcus-like spores (paragraph 105). Fibrin forming a few minutes after the specimen is made becomes "fine flagella appearing in the field in places where nothing had previously been seen" (paragraph 107).

If I have misinterpreted Surgeon-Captain Hehir's descriptions it is entirely owing to the bad manner in which they are written. But I do not think that such misinterpretation is possible, because no other bodies and appearances which in any way resemble those descriptions exist in the blood. Of the large number of able observers who have studied malarial blood not one has even hinted at the existence of such forms. Surgeon-Captain Hehir insists upon the use of high powers and special methods of staining; but other observers have used these without arriving at his results. On the other hand, I really doubt whether he has ever seen the true parasite at all. For example (paragraph 38), he says that "it is often difficult to distinguish red cells from spherical bodies of different kinds, including the spherules which have developed from the unfolding of crescents"; a child could distinguish them. Again (paragraph 76), he says that the red cells (occupied ?) are smaller than the average in the tertian parasite, which is just the opposite of truth, as every beginner knows by this time. He must have been looking at something quite different from what most of us hold to be the parasite of malaria. That a beginner should be misled in this way is credible, but that Surgeon-Captain Hehir should persist in ventilating such matters years after the true nature of his bodies has been exposed (not only by myself, but by Mr. Hankin, and, I think, by others), while at the same time he refuses or omits to answer satisfactorily reasonable criticisms, is becoming a kind of nuisance in medical literature. If he still believes in his discoveries his course is (*a*) to demonstrate to capable persons; (*b*) to publish photographs; and (*c*) to send specimens to impartial experts in Europe. Until his observations are confirmed by others we are, I think, justified in holding that he has been misled by "pseudo-parasites," and that the parasites of malaria and cholera described by him are zoologically impossible and exist only in his imagination. If he pleads that similar things have been said of other discoverers we must reply that they have at least endeavoured to convince others by visual demonstrations and exact descriptions.

I am, Sirs, yours faithfully,
RONALD ROSS, Surgeon-Major, I.M.S.
(Parkes' Memorial Gold Medalist on Malaria).

*** Surgeon-Captain Hehir referred in his paper to illustrations which were to reach us later.—ED. L.

"HAS THE FISH A MEMORY."

To the Editors of THE LANCET.

SIRS,—I have to thank you for quite a number of most interesting letters which were addressed to me in consequence of your article containing my question—Have fish a memory? I see that such studies in comparative psychology interest more people than I believed. Perhaps your readers might take an interest in an address made at the Association of German Physicians and Naturalists, 1896. This address, which was made at the request of the Scientific Committee of the Congress, contains the very essence of my views and forms, as I should say, the prelude to the question you lately were kind enough to insert in your paper.

I am, Sirs, yours truly,
Frankfort-on-the-Main, Jan. 28th, 1897. LUDWIG EDINGER.

To the Editors of THE LANCET.

SIRS,—In a book published by Messrs. Cassell in the early seventies, called "The World of Wonders," occurs the following story:—

"When the late Dr. Warwick resided at Durham *(sic)*, the seat of the Earl of Stamford and Warrington, he was walking one evening in the park, and came to a pond where fish intended for the table were temporarily kept. He took particular notice of a fine pike, of about six pounds weight, which, when it observed him, darted hastily away. In so doing it struck its head against a tenter-hook in a post (of which there were several in the pond, placed to prevent poaching), and as it afterwards appeared, fractured its skull and turned the optic nerve on one side. The anguish evinced by the animal appeared most horrible. It rushed to the bottom, and boring its head into the mud, whirled itself round with such velocity, that it was almost lost to sight for a short interval. It then plunged about the pond, and at length threw itself completely out of the water on to the bank. The doctor went and examined it, and found that a very small portion of the brain was protruding from the fracture in the skull. He carefully replaced this, and with a small silver toothpick, raised the indented portion of the skull. The fish remained still for a short time, and he then put it again into the pond. It appeared at first a good deal relieved, but in a few minutes it again darted and plunged about until it threw itself out of the water a second time. A second time Dr. Warwick did what he could to relieve it, and again put it into the water. It continued for several times to throw itself out of the pond, and with the assistance of the keeper, the doctor at length made a kind of pillow for the fish, which was then left in the pond to its fate. Upon making his appearance at the pond on the following morning, the pike came towards him to the edge of the water and actually laid its head upon his foot. The doctor thought this most extraordinary; but he examined the fish's skull and found it going on all right. He then walked backwards and forwards along the edge of the pond for some time, and the fish continued to swim up and down, turning whenever he turned; but being blind on the wounded side of its skull, it always appeared agitated when it had that side towards the bank, as it could not then see its benefactor. On the next day he took some young friends down to see the fish, which came to him as before, and at length he actually taught the pike to come to him at his whistle and feed out of his hands. With other persons it continued as shy as fish usually are. Dr. Warwick thought this a most remarkable instance of gratitude in a fish for a benefit received; and as it always came to his whistle it also proved what he had previously disbelieved, that fishes are sensible to sound."

Perhaps this story may interest Professor Edinger.

I am, Sirs, yours faithfully,
CREDAT JUDAEUS.

To the Editors of THE LANCET.

SIRS,—From a paragraph in the *Standard* I learn that you are asking for any observations that may have been made having reference to the question as to whether a fish has a memory. I beg to submit the following. A few years ago I kept a small tench in a fish-globe alone and gave it from time to time various articles of food—worms, flies, &c.,—but among all these there was but one thing that raised any excitement in the fish's "mind," and that was the sight of a small worm. This being held at a considerable distance—even so much as six feet—caused a manifest excitement. We used to think it incredible at first that the fish recognised so small an object, but we found upon observation, many times repeated, that the fish was quite well aware of the dainty in store. He would take it greedily from our hand. I cannot conceive but that memory played an important part here. I should have said that the worm was brought from a distance gradually and *not* shown to the fish at first.

I am, Sirs, yours obediently,
Felstead, Jan. 24th, 1897. J. FRENCH.

*** We cannot receive any more communications on this subject. Correspondents are requested to send any facts they may have at their disposal to Professor Edinger, 30, Gärtnerweg, Frankfurt-on-Main.—ED. L.

THE MIDWIVES BILL, 1897.

To the Editors of THE LANCET.

SIRS,—The above Bill was read a first time in the Commons on Feb. 9th and was down for second reading on Friday, 12th. Fortunately, its second reading was not reached. It is truly lamentable that a Bill such as this, which proposes

Hosted by Google

to establish a new class of midwifery practitioners, should be placed for second reading and not one word of warning be given us in any of the four weekly medical journals. A copy of the Bill can now be had from Eyre and Spottiswoode, East Harding-street, S.E., price 2*d*.

This Bill is, of all its predecessors, the most dangerous, because it attempts to leave out the chief debateable points, handing these over to the proposed "Midwives Board." But as this Board is to consist of practitioners to be elected, three each, by the College of Physicians, College of Surgeons, and Apothecaries' Society, and Midwives Institute, and six by the Lord President of the Privy Council, we can form a fair idea of the composition of such Board. I should like to know if the Colleges and society have agreed to the above, and if not, what is to happen? My hope is that the Colleges and society will refuse to dirty their hands with any so degrading a proposal. Clause 5 (*b*) proposes that the Representatives of the Colleges shall "appoint examiners"—that is, the Colleges shall appoint examiners both under the Medical Acts to *license* medical practitioners, and also examiners to *license* an inferior class of midwifery practitioners, to be known under the misleading name of "midwives." Surely the Colleges and society will never agree to carry on this double plan of down-grade examination, and so establish two classes of *women* licentiates. Another important point is that no provision is made for the payment of the expenses of the eighteen members of this Midwives Board. If Members of the Medical Council are paid, why should not also Members of the Midwives Board? Badly paid public work is always badly done work.

Again, no provision whatever is made for the election of representatives *of the profession* upon this Board. Why? The profession has, for so far, five direct representatives upon the Medical Council. Yet it is refused representation upon this Board. It is not as if *all* diplomates of the Colleges and Society were to be empowered to elect the representatives of the Colleges and Society upon this Board, because such would be elected by the councils of the Colleges. In these respects, therefore, the Bill is glaringly deficient. Clause 5 is worthy of the closest attention. It is to be noticed that the Board is to frame rules "for *approval* by the Medical Council." But if these rules are for "*approval*" only, what is the good of the Medical Council discussing them? Should the words not be for the "approval or otherwise" of the Medical Council?

Another grave flaw in the Bill is, that it refuses to give the Medical Council power to take any part in arranging the plan for *the education* of intending midwives. Clause 5 lays down the *duties of the Board* in Sub-clauses *a*, *b*, *c*, and *e*, while Clause 5, Sub-clauses *d* and *f*, lay down the duties of the Medical Council. By this clause, therefore, the Medical Council is to be empowered (*a*) to constitute the Board; (*b*) "to approve" (!) rules regulating *the admission to the Register of women already in bonâ fide practice*"; and (*c*) to approve (!) rules for "regulating, supervising, and restricting" the practise of midwives. Therefore, neither in Clause 5, nor in any other of the clauses, is the Medical Council given the slightest power to say in what subjects the intending midwife is to be *educated* and in what subjects she is not. This drafting is painfully at variance with the resolution of the Medical Council, November, 1889, which refers specifically and in detail to "*the education*, examination, and discipline which ought to be established." Clause 9 is of interest to medical officers of health, as it proposes every local sanitary authority shall appoint its medical officer of health to act as the "local supervising authority," and it is proposed that he shall (*a*) supervise all midwives practising in his district; (*b*) investigate charges of malpractice, &c.; (*c*) report to the Midwives Board any midwife convicted of misdemeanour; (*d*) keep a correct copy of the Register of Midwives; (*e*) satisfy himself of the right of any midwife to practise; and (*f*) notify the deaths of midwives to the Board. This will be no small work for any local medical officer of health, but when I state that no provision whatsoever is made in the Bill for payment for such services we can see how it is intended the Bill should be administered. I hope every "local" medical officer of health will write to his M.P.'s asking them to oppose the Bill. An important point is that all through the Bill those responsible for it *have persistently* refused to *define the duties* of the midwife—i.e., they refuse to say whether she is to act as a nurse only and under the direct supervision of a medical practitioner or to conduct confinements on her *sole* responsibility. It is proposed to harness the Midwives Board with the defining of her duties and with defining the undefinable word "natural labour." Now until this is done *in the Bill, and in the Bill only*, we must strenuously oppose it.

When the Midwives Bill was before the Medical Council in 1895 it was referred to a committee of the Council. This committee reported against the Bill as follows: "That the word 'midwives' should be struck out of the title of the Bill and out of the several clauses and that the term 'midwifery nurse' be substituted for it." The committee also proposed and agreed that instead of the midwife being empowered to attend natural labours without the supervision of a medical practitioner the Bill should empower her, "but not to discharge any other duties than those of a midwifery nurse." When this committee report came up before the Council the motion that the words "midwifery nurse" be substituted for the word "midwife" was defeated by only 14 votes to 12. Again, when it was moved by Dr. McVail and seconded by Dr. P. H. Watson that the duties of the midwife shall be to attend natural labours under the direct supervision of a registered medical practitioner this was lost, on a vote, by 14 to 9, no less than seven members present, being so undecided, refusing to vote. Does this look like unanimity of the Medical Council in supporting this society craze to repeal the Medical Act, 1886, and to supply the poor—and, mark this, the poor only—with an inferior grade of midwifery practitioners?

The lessons taught by the late election of Direct Representatives to the Medical Council; the insult offered to the profession in Liverpool when the medical staff of the lying-in hospital was discharged and a midwife placed over them; the action of the Leicester board of guardians in appointing a midwife to take the place of their district medical officer; the action of the Peterborough guardians in petitioning every Poor-law authority to obtain power to discharge their district medical officers, and to appoint midwives in their stead to conduct all confinements; the fact that the Midwives Bill of 1890 proposed to empower midwives to attend *all kinds* of labours and to use instruments; the fact that subsequent Bills proposed to confine the midwife to attending "natural labours," and at the same time persistently shrank from giving a definition of "natural labour"; and the fact that those responsible for this impossible Bill now hope to get over all their difficulties by referring them to a Midwives Board, only proves the truth of Lord Cranbrook's reply when, in March, 1891, he said to a deputation in favour of the Bill: It is "an impossible Bill and one which would not meet the merits of the case." To-day is the day of faddists. How can this Bill be defeated? The Bill is "backed" by the following members of the House of Commons: The Hon. A. de T. Egerton (Knutsford), C E. Schwann (Manchester, North), Sir F. FitzWygram (Fareham, Hants), Skewes-Cox (Kingston, Surrey), H. C. O. Bonsor (Wimbledon, Surrey), C. Fenwick (Wansbeck, Northumberland), Sir J. T. Woodhouse (Huddersfield), C. Harrison (Plymouth), J. Wilson (?), H. R. Graham (St. Pancras), C. Bill (Leek, Staff.), and J. H. Johnstone (Horsham, Sussex). If each practitioner in one or other of the above divisions will write at once to these Members of Parliament asking them to withdraw the Bill as it is strongly opposed by the profession great good will result. Also, if all other practitioners will write their M.P.'s asking them to oppose the Bill, and if they will get their local coroners, county councillors, and local political leaders to write to their M.P.'s, then the Bill will be withdrawn. I would also urge that practitioners resident in Ireland and Scotland do the same. It is said the Bill does not apply to Ireland and Scotland. That is true in theory, but false in fact, because the Midwives Board in England would license midwives to practise in Ireland and Scotland, just as now the medical bodies license practitioners to practise in the Isle of Man. It is to be remembered that there are now eight medical Members of Parliament—viz., Sir W. Foster, Sir Wm. Priestley, Drs. R. Farquharson, G. B. Clark, C. K. Tanner, M. A. MacDonnell, R. Ambrose, and J. A. Fox,—and that as not one of these would put their name to the back of this Bill we can see how our opposition has gained support. In 1890 no less than three medical M.P.'s "backed" the Bills of that year. I believe Sir R. B. Finlay, M.P., and Mr. J. Dillon, M.P., are both of the medical profession. If then practitioners resident in the divisions represented by the above will write to them, and ask them to oppose the Bill, I feel certain a

Hosted by Google

courteous reply will be given. I would just add there is little good in supposing that Members of Parliament will be guided by what I alone write to them. The Member of Parliament wishes to know, not what I alone say, but what his constitutents want. If the majority of practitioners in *each constituency* in the United Kingdom write to their M.P. to oppose the Bill, then no Bill can pass.

In *1894* eight medical societies and nine branches of the British Medical Association, comprising 3324 practitioners, voted against Registration of Midwives, and only 392 for.

In *1895* the annual meeting of the British Medical Association passed a very strong resolution against the proposal; and in 1896 the Council of the Association resolved:—

"1. The Bill practically abrogates the existing Medical Acts as regards the practise of midwifery. 2. That it is fraught with danger to the public, inasmuch as it contemplates the creation of an inferior order of practitioners to attend upon the poor. 3. That it is unjust to the medical profession, inasmuch as it proposes to register an inferior order of practitioners, instead of a body of well-qualified midwifery nurses.

"Resolved:—That the Council be requested to prepare a petition for presentation to the House of Commons embodying reasons against the Bill."[1]

Mr. F. Fowke informs me Sir W. Foster presented the petition, May, 1896. In an editorial in THE LANCET[2] reference is made to a midwife who operated upon an infant, it bleeding to death, and where it is stated:—"Midwives are of great value to a community when it is fully recognised that they are specially *trained nurses* and *nothing more*." I shall be glad to hear from any practitioners willing to do their duty and who have received promises of support.

I am, Sirs, yours truly,

ROBERT R. RENTOUL.

Hartington-road, Liverpool, Feb. 14th, 1897.

MR. LOCH AND THE ABUSE OF HOSPITALS.

To the Editors of THE LANCET.

SIRS,—I feel confident that the thousands and tens of thousands interested in the welfare and progress of our hospitals—everyone working for them without fee or reward, as well as those receiving for their services far less than a living wage—and the millions of people too poor to pay for help in sickness, or in consequence of accidental injury, in all parts of the world, will join in begging Mr. Loch and his friends to abstain from further interference with regard to the so-called "abuses" of hospitals and other medical charities during this one year—1897—only. In 1898 we may fully discuss and, I hope, finally settle many of the important and interesting questions again brought forward in his letter to the *Times* of Feb. 12th, 1897, and in other communications with greater freedom and at more leisure than is at this time possible, without fear of damaging the financial interests of our hospitals and other institutions founded and supported for the benefit of our sick poor, and without any risk of wounding the susceptibilities of those whose love of their hospitals is of life-long duration.

For these and some other reasons I think it better to postpone the observations I desire, with your permission, to bring before the profession with reference to the highly important and enormously complicated question of the best means of restoring to health in the shortest time people suffering from sudden, acute, or chronic maladies, who cannot possibly afford to pay for medical services and provide for the expenditure consequent upon inability to work. Many of my medical friends will, I am sure, gladly assist in the consideration of matters of such consequence, and as by that time I shall have completed fifty years of active and almost continuous hospital work I may also be permitted, without being accused of presumption, to bring before the profession some of the views I have been led to form, which differ in many respects from those entertained by Mr. Loch, and persistently advocated by him for many years.

If, however, the organising enthusiasm of Mr. Loch and his friends renders a year's rest from their labours unbearable I venture to recommend during the interim an inquiry into a matter which might be undertaken with advantage, and which bears in some degree upon the causes of the complaints of practitioners in certain neighbourhoods who think that their interests have been seriously affected by the increasing popularity of the out-patient departments of our hospitals, though it seems probable that other circumstances have been operating at the same time and perhaps in greater degree to bring about the state of things which all of us so much regret. Among these must be included the fact of the enormous number of new remedies which have been introduced during the last few years, and new methods of treatment which are continually being pressed upon us. Medicines in the inviting form of tabloids, warranted to cure all sorts of ailments, have been brought into public notice in all possible ways and at vast expense. Now it would be of great service to the public, the profession, and to the poor if the most useful and the many worthless among these could be pointed out. Many have come to us from America and many from Germany; not a few have been found by some of us who have tried them to be of little use, and some positively inert; while a few coming, I think, from France, though, perhaps, made elsewhere, are too violent in their action, and some are uncertain. We desire very much to ascertain the truth with regard to the beneficial action or otherwise of many of these medicines with which we are inundated and which are too numerous to remember. Here, then, is an inquiry useful to the public and the profession, and, at the same time, offering a wide field for the labours of those skilled in financial educational and statistical investigations of much importance in reference to hospital management and finance, for the cheapness of many of these medicines is, indeed, remarkable, and the small space they occupy would enable those skilled in organisation to establish small dispensaries everywhere for sale to the necessitous poor at a very cheap rate—say, a halfpenny for twelve doses and a halfpenny for the advice given. In time the dispensaries would become self-supporting, the out-patient departments of our hospitals would suffer in popularity, and ere long the great desire of Mr. Burdett—the extinction of the present system of treating multitudes of out-patients in our hospitals—would be gratified.

I am, Sirs, your obedient servant,

Feb. 15th, 1897. LIONEL S. BEALE.

"SHOULD EPILEPTICS MARRY?"

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 13th Mr. Thistle asks, "Has Dr. Gowers any special reason for supposing that accidental lesions of the brain are less liable to be transmitted than similar lesions of the eye or the finger, instances of which are so frequently brought under our notice?" My answer is that I have no reason to believe it, but that no instance of the two examples he mentions has ever come under my notice directly or indirectly. Since it is the opinion of some of those who have given most attention to the subject that such transmission never occurs, Mr. Thistle should certainly publish some of the instances that so frequently come under his notice. An interesting letter appears in the last number of *Nature*, mentioning that Dr. Pritchard long ago anticipated very definitely the recent conclusions of Galton and Weissmann that such transmission of acquired characters does not occur.

I am, Sirs, yours faithfully,

W. R. GOWERS.

Queen Anne-street, London, W., Feb. 15th, 1897.

THE POSITION OF THE AURICULO-VENTRICULAR CUSPS DURING SYSTOLE.

To the Editors of THE LANCET.

SIRS,—I have for some fifteen years been wondering why the theory attributed to Parchappe as to the action of the auriculo-ventricular valves is not taught in England, and during the last few weeks I have several times been made aware that it is generally unknown in this country. Now, since it explains cardiac sounds which are otherwise difficult to understand, and has been accepted by such men as Burdach, Purkinje, and more recently by Malherbe and Fossion, who have developed it, and J. Beclard, who admits it in the seventh edition of his "Physiology" (1880), surely it is time that every practitioner considered it. Marc Sée, in his "Researches on the Anatomy and Physiology of the Heart" (Paris, 1875), still further elaborates it, saying that the effect of the contraction of the musculi papillares, which takes place at the same time as that of the muscular walls of the

[1] See Brit. Med. Jour., May 2nd, 1896, p. 1117.
[2] THE LANCET, Jan. 23rd, 1897, p. 225.

Hosted by Google

ventricle, is to stretch the chordæ tendineæ and pull down the auriculo-ventricular curtains, and this in spite of the shortening of the longitudinal diameter of the ventricle admitted by most writers. The musculi papillares of the left ventricle are placed in such a way that they fit into one another and fill up the left part of the ventricular cavity. In contracting they pull the two flaps of the mitral to the left, applying them one against the other and against the wall of the ventricle. In the right ventricle the papillary muscles apply the flaps of the tricuspid to the surface of the partition. Without comment, which is unnecessary, I will ask you kindly to insert this in an early issue of your widely-read journal, and oblige,

Yours faithfully,

Inverness-gardens, W. G. COCKBURN SMITH.

"AN UNUSUAL RESULT OF ABORTION."

To the Editors of THE LANCET.

SIRS,—Dr. Purslow's case of abortion, in which the fœtus was embedded in the unruptured amnion only, is interesting from its rarity. This peculiar result (brought about by the rupture of the external membranes and of the funis at the site of its attachment to the placenta) has been observed and recorded on several occasions. A similar case will be found in the Obstetrical Transactions, vol. xxxiii., p. 462, recorded by the late Dr. Graily Hewitt, with an excellent drawing by Mr. Lawrence, the Curator of University College Museum; also a reference to a case by Dr. Herman and by Smellie. Dr. Winckel has also published an observation of the same kind, with a drawing, in his Text-book of Midwifery.

I am, Sirs, yours faithfully,

Mansfield-street, W., Feb. 12th, 1897. HERBERT R. SPENCER.

"THE GLANDULAR FEVER OF CHILDHOOD."

To the Editors of THE LANCET.

SIRS,—Having had five of my children ill with the above fever I read with interest Dr. Dawson Williams's paper on the subject in THE LANCET of Jan. 16th. I will not go over the ground already traversed by Dr. Williams, as I can endorse most of what he says. I do not, however, find that either the author or those who have written since the date of the paper refer to a complication which occurred in four out of five of my own cases—namely, epistaxis. The youngest child, aged three and a half years, bled from the nose one night to such an extent as to seriously imperil life, and the others bled pretty freely. I also observed that although the fever rose in two of the cases to 104° F. there was neither delirium nor vomiting. When convalescence fairly set in the appetite was voracious, and the recovery has in all cases been complete. It is worthy of note that the first case occurred during a visit to an obscure part of South Wales. A word as to treatment. The severe pain in the neck was relieved by lint smeared with extract of belladonna and glycerine. When this failed lint soaked with tincture of opium and water (1 to 4) and covered with oiled silk always eased the pain. The only drug which appeared to be of any avail was salicin in from three-grain to five-grain doses every four hours. One grain of calomel occasionally, always did good. Grapes were given freely when the pain in the neck allowed of swallowing, and, if anything, they relieved the abdominal pain.

I am, Sirs, yours truly,

Weymouth-street, W., Feb. 10th, 1897. CHAS. W. CHAPMAN.

ANTI-VIVISECTIONIST TACTICS.

To the Editors of THE LANCET.

SIRS,—The death of the great specialist, Sir Spencer Wells, who certainly did not attain his unrivalled skill as an operator—a skill which has prolonged life and restored health in innumerable cases—without resort to vivisection, seems a fitting opportunity for calling attention to the renewal of the unscrupulous attempts of the anti-vivisectionists to blast the reputation of the medical profession and to ruin the hospitals. Twice within the past month I have been called upon—once by a man, apparently a paid agent, and once by two young ladies, who have probably allowed sentiment to obscure reason, canvassing from house to house for signatures to a petition insidiously represented as "for securing kindness to animals," but which is only the old anti-vivisection petition accompanied by literature of exaggerated virulence. I enclose the leaflet left by the canvassers and ask whether something ought not to be done to check this wholesale slanderous vituperation?

I am, Sirs, yours truly,

Feb. 9th, 1897. A. W. BUCKLAND.

CASE OF DERMATITIS DUE TO WEARING A FUR COLLARETTE.

To the Editors of THE LANCET.

SIRS,—As some attention is being drawn to the eruption caused by fur the following case may be of interest. A young woman, who had never been subject to eczema, consulted me in November last as to a rash on her neck. The eruption was about two inches broad, extending, but for a few inches in front completely round the neck and even on to the lower part of the cheeks. There was less behind than at the sides, the eruption being particularly marked on the thin skin over and just posterior to the sterno-mastoids. It consisted of fine discrete papules, intensely irritable, scattered more closely toward the centre, and fading off toward the edge of the eruptive band. It appeared that the woman had recently purchased a fur collarette, and on this lay my suspicions. I requested her to desist from wearing it till it had been subjected to steam cleaning, as I thought then that the eruption was caused by some poisonous dressing. The fur was accordingly steamed and afterwards worn; but the eruption showing no signs of abatement I obtained a piece of the fur in order to make a minute examination of the hairs. I found that the fur was composed for the most part of short, even-lengthed hairs of extreme tenuity, but scattered among them were long, bristle-like hairs which seem absent in good young pelts. These hairs split and fracture very easily, the points of such fractured hairs being extremely sharp and almost horny. It is, therefore reasonable to presume that when pressed in contact with the thin skin of the neck the bristly hairs penetrating the cutis break off and thus give rise to the eruption. I venture to send you a specimen of the fur and a few bristles mounted for the microscope to demonstrate the fractured ends.

I am, Sirs, yours faithfully,

Kensington, W. E. A. B.

*** We may point out that the above conclusions of our correspondent are similar to those we published in the columns of THE LANCET a fortnight ago—conclusions which were based on experimental results with a specimen of both an irritating and a non-irritating fur collarette. At the same time we established the absence of chemical irritants.—ED. L.

THE CANTONMENT AT QUETTA.

(FROM A CORRESPONDENT.)

WHETHER the poison which causes enteric fever and other allied affections be animal, vegetable, or mineral, and whether its habitat be aquatic, aerial, or telluric, the importance of a clean wholesome site for a dwelling must be admitted by all theorists. No conscientious builder would construct a house over an unemptied cess-pit, and yet this is precisely what was done when the present cantonment at Quetta was founded.

During the last war in Southern Afghanistan a great camp grew up by degrees round a remarkable tumulus-like mound known as the "Miri," which is situated in the centre of a spacious alluvial plane at the northern outlet of the Bolan pass. From time immemorial the site had been the regular halting-place for caravans between Kandahar and India, and it is no exaggeration to say that the subsoil was everywhere saturated with noxious organic matter. That, under the circumstances, the troops and followers should suffer severely from diarrhœa, dysentery, enteric fever, and pneumonia was

Hosted by Google

a foregone conclusion; but happily—thanks to the magnificent climate, and thanks also, no doubt, to a careful supervision of the water-supply—the mortality, though high, was not so great as might have been expected.

Kandahar having been abandoned in the spring of 1881, the breaking up of the Southern Afghanistan Field Force followed soon afterwards; whereupon the question of a fresh site for the headquarters of the newly-formed Quetta District was immediately raised by the recently appointed principal medical officer. Fully imbued with the hygienic gravity of the situation, this official lost no opportunity of impressing upon the authorities, military as well as medical, the overwhelming advantages of a virgin soil for the new cantonment. To his mind complete removal from a site contaminated by the filth of centuries was an obvious necessity, and he accordingly begged leave to point out two fresh sites in the neighbourhood of the ancient halting-ground which seemed to him to be suitable in every respect. In consequence of these representations a special committee was appointed to inquire into the matter, and after due inspection and deliberation the selected spots were both declared to be at least as free as the old foul site itself was from strategical defects and military objections. The sanitary faults of the existing camp being so self-evident the principal medical officer felt sure his condemnation would be endorsed by the executive in India, but month after month passed without a sign, and at last, when the year (1881) closed in leaving the question still in abeyance, he began to lose hope. By this time buildings instead of tents had commenced to spring up in every direction, and although it was true that these more or less rude shelters were constructed of sun-dried brick and represented little or no money value still the disheartened sanitarian could not but regard them as so many nails in the coffin of a salubrious Quetta.

The inexorable touchstone of events has long since justified this melancholy prognostication. It cannot be denied that during the last sixteen years all the diseases that are usually associated with a foul subsoil, from cholera downwards, have committed terrible ravages in the Beloochistan outpost, but even now at the eleventh hour it is not too late to apply a remedy. The past, unfortunately, is irrevocable, but it is our duty to safeguard the future as far as possible, and to this end the recommendation of 1881 cannot well be improved upon. Attention has been drawn[1] to a recrudescence of enteric fever at Quetta, but the fact that this fatal disease has become endemic is not to be wondered at. The climate, however, of the whole district is so good that our soldiers ought to be quite as healthy at Quetta as in England. Air, food, and water are all of the best; it is only the soil that is at fault, and manifestly nothing short of a complete change of site can effectually remove this extremely serious blemish.

It is given to many people to be wise after the event, but the first Principal Medical Officer of the Quetta district may be included in the rarer category of those to whom prophecy is permissible because they happen to know. The testimony of the crowded cemetery on that far-off table-land is, unhappily, only too conclusively in favour of the genuineness of his foresight, but, Cassandra-like, he failed to convince those with whom was the power. Should the authorities desire to refresh their memories as to the views held by this officer regarding possible sites for a cantonment on the Quetta plain, they will find them set forth at length in the annual (medical) report of the Quetta district for the year 1881, which was duly forwarded to Simla early in 1882. As this was the first document of the kind which emanated from the command it has doubtless been carefully preserved in the archives of the Government of India.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Manchester Royal Infirmary.

THE annual meeting of the trustees of the Manchester Royal Infirmary was held on Friday last. In the absence of Mr. E. S. Heywood, chairman of the board, Mr. J. W. Maclure, M.P., presided. The report stated that, as sanctioned by Parliament, the Monsall Fever Hospital was handed over to the Manchester Corporation on Oct. 1st last, "on the payment by them of the sum of £4899 10*s.* 7*d.*" Provision is made for the gratuitous removal and treatment at the hospital of all cases of infectious disease arising at the infirmary or at the convalescent hospital at Cheadle, and the members (of the infirmary medical staff are to have facilities for giving clinical instruction within the wards of the hospitals of the Manchester Corporation. A small second operating theatre has been constructed at the infirmary at a cost of £250, which will greatly facilitate the surgical work of the institution. During the year 1896 4534 in-patients, 36,908 out-patients and surgical casualties, and 1135 home-patients have been treated. The total reaches the large number of 42,577, against a total of 41,205 in the previous year, the increase being chiefly in the out-patients. The following sums have been received from the patients who were able and willing to contribute to the cost of their maintenance:—In-patients, £826 16*s.* 1*d.*; out-patients, £73 13*s.* 6*d.*; Convalescent Hospital patients, £133 17*s.* 2*d.* The report states that from the inquiries made by the District Provident Society into the circumstances of all patients living in Manchester, "it has been ascertained that 93 per cent. of the cases visited last year were fit objects of charitable relief." With respect to this statement, a letter signed "Hospital Reform," which appeared in the *Manchester Guardian* of yesterday, may be noted. It says: "A simple calculation shows that no less than 2979 cases were not suitable objects for charitable relief." In the same isssue Mr. T. Garrett Horder, referring to a paper read by him in November last before the Manchester Medico-Ethical Society, calls attention to the fact that while 249 out of every 1000 inhabitants of Manchester were registered as out-patients at the Manchester hospitals in 1892, the out-patients at the Oldham hospitals only numbered 33 per 1000 inhabitants; and he says that he thinks this great difference may be accounted for by the fact that at the Oldham Infirmary "there is a Special Admission Committee, whose duty it is to make investigation into the circumstances of people who apply for out-patient medical relief." This seems to show that the tests of the District Provident Society are less stringent than those of the Oldham committee; or is it that the difference is caused by the large number of patients applying at the infirmary who are not resident in Manchester and into whose circumstances therefore no enquiry is made? The income of the Infirmary last year was £22,441; in 1895 it was £22,627. The ordinary expenditure during the year was £17,073—Convalescent Hospital, £5621; Monsall Fever Hospital (nine months to Sept. 30th), £11,624. The cost of wines, spirits, and malt liquors was 1*s.* 4½*d.* per patient. The chairman in moving the adoption of the report, said that after the declaration of the trustees they would continue to maintain the hospital on the present site. It was arranged that there should be a friendly conference between representatives of the trustees and of the Manchester Corporation. The committee had been appointed and, he believed, would meet very shortly. Mr. Fildes said he had attended the meeting as a member of the hospital committee of the Manchester Corporation to express his cordial acknowledgments—in which he was quite well aware his committee would desire to associate themselves—of the exceedingly generous and gracious manner in which the transfer of the Monsall Hospital had been made to the Corporation. One point in connexion with this transfer gave rise to some anxiety when the question was first mooted—namely, the provision for clinical teaching in cases of fever, and it is eminently satisfactory that the Corporation, with the guidance, no doubt, of the medical officer of health, has been sufficiently enlightened to continue to the students of the Owens College Medical School the opportunity of obtaining, with the help of the infirmary medical staff, this essential part of a medical education.

Bequests to Medical Charities.

The will of the late Mr. James Parrott, a Salford engineer, who died on the 5th inst., aged ninety-four, besides giving legacies and annuities to relatives and others, makes the following bequests to Manchester medical charities: the Royal Infirmary, Royal Eye Hospital, St. Mary's Hospital, and Salford Hospital, to each £500; to the Homœopathic Hospital, £500; to the Consumption Hospital, £400; to the Ardwick Dispensary, the Chorlton-on-Medlock Dispensary, the Ear Institution, and the Children's Hospital, Pendlebury, each £200. The United Kingdom Alliance, Manchester

[1] THE LANCET, Jan. 9th, page 133.

Hosted by Google

receives £500. and the Vegetarian Society, Manchester, £200. Henshaw's Blind Asylum and the Deaf and Dumb Schools, Old Trafford, each receive £500. Various other bequests are made to philanthropic societies, and to "any hospital within Manchester conducted on total abstinence principles and selected by the trustees within ten years, £1000." The residue is to be held as a trust, to be called "The James Parrott Charity," the income of which is to be applied "in making money grants, or weekly or other periodical allowances, towards the succour, aid, or relief, of poor people inhabiting or dwelling within the boroughs of Manchester and Salford, and the district of South Shore [Blackpool, where he died], especially such poor people as, by reason of sickness, infirmity, or age, are peculiarly objects of charity." The will directs that there shall always be three trustees. The deceased gentleman is said never to have used tobacco, to have been a total abstainer from alcohol for nearly seventy years, and to have been a vegetarian for forty years. He certainly did credit to his regimen, for he was a hale, well-preserved old man, who superintended his engineering works in Salford until he was eighty-eight years old.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

St. Andrews and Dundee.

THE anticipation that the recent decision of the Privy Council confirming the ordinances issued by the University Commissioners, by which an incorporating union was established between the University of St. Andrews and University College, Dundee, would conclude the long quarrel between these two academic bodies has been promptly dispelled. At a meeting of the University Court, held on the 10th inst., a letter was read from the Duke of Argyll, Chancellor of the University, intimating that he had taken the opinion of counsel on the ordinances, and was advised that an action for reduction would be competent. Thereupon the Court decided by a majority to take no action in connexion with the ordinances regulating the union of the Dundee College with the University and to intimate their willingness to supply any information that may be needed for the purpose of promoting the suggested legal proceedings. This decision practically ignores the finding of the Privy Council and is in direct opposition to an intimation from the University Commissioners declaring that the ordinances are to be carried out without delay. It will be interesting to see how these two august bodies will deal with what looks like an act of open rebellion against authority. In the meantime it appears to be the determination of the Court to proceed without any recognition of the existence of Dundee or of the authoritative decisions in reference to the College and the University. Thus, at the meeting of the court at which the decision above alluded to was taken the minutes of a committee appointed to make arrangements for the erection of new buildings for a medical school in St. Andrews were adopted, whereas in the scheme of union the medical school of the University was practically to be the college and hospital at Dundee. It is right to add that in this policy the court is by no means unanimous, and the last decision was only carried by the casting vote of the chairman, the Marquis of Bute. The minority includes such influential names as those of Principal Donaldson and Professor Stewart.

Post-graduate Teaching in Glasgow.

It is intimated that Professor Coats is during March and April to conduct two post-graduate courses in the Pathological Institute of the Western Infirmary, one in bacteriology and the other in practical pathology. Each course is to commence on March 4th, and the two may be taken together or separately. The clinical demonstrations to medical practitioners, which were commenced some weeks ago in the Royal Infirmary, have been highly successful. A large and increasing number of practitioners are attending the demonstrations and much satisfaction is expressed at their thoroughly useful and practical character.

Provincial Hospitals.

The annual meeting of subscribers to the Ayr County Hospital was held on the 15th inst. The general condition of the hospital was reported to be satisfactory, but, as in most cases, the income falls below the expenditure. It is proposed to try to raise a sum of money in connexion with the "Diamond Jubilee" for the purpose of removing the debt of £800 and to increase the endowment of the hospital. By the will of the late Provost Alexander of Coatbridge a sum of £30,000 has been placed in the hands of trustees to erect a hospital more particularly for the treatment of patients injured by accidents occurring in the numerous ironworks in the neighbourhood. The erection of the hospital is to be proceeded with immediately.

Feb. 16th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Health of Dublin.

SOME excitement has been caused here by the leading articles and letters which have recently appeared in the daily journals in reference to the high death-rate which now exists in Dublin. In a leading article on the 10th inst. the *Freeman's Journal*, while repudiating the attitude of an alarmist, maintains that the Dublin death-rate since the beginning of 1897 has been so high as to warrant even more stringent comment than it has actually called forth, and while disclaiming any wish to apportion blame to any public body of staff of officials, the writer fails to see how this important matter can be overlooked. He states that during the first five weeks of the present year the Dublin death-rate averaged 40·1, and was therefore 6·2 above the mean rate for the corresponding period of the past ten years. Every credit is given to the superintendent officer of health and his staff for the fair record which the city returns show for the six years ending with last year, the mean death-rate from zymotic disease in Dublin being for that period decidedly satisfactory and under that of the thirty-three great towns of England, including London. The death-rate, moreover, for the year 1896 was especially favourable. The gravity of the present epidemics and the high mortality now prevailing in Dublin are, on the other hand, prominently noted. Professor Roche's letters and comments have indeed served to draw from Sir Charles Cameron, the superintendent officer of health, full notice, and his reply to all faultfinders is about to take the shape of a communication to the Royal Academy of Medicine in Ireland. It is entitled, "The Recent Failure of Hospital Accommodation in Dublin," and will be read at the meeting of the Section of State Medicine on the evening of the 19th.

The New Belfast Hospital and the Railway Companies.

At a special meeting of the County Down Railway Company, held last week, £1000 were voted to the new Belfast Hospital; but at the meeting of the Northern Counties Railway the chairman announced that the directors, in face of threatened opposition, felt it would not be judicious to put the resolution authorising them to subscribe £1000 towards the erection of the proposed new hospital. It seems that such a proposition can only be carried out by the unanimous vote of the shareholders, and one of them had intimated that he would oppose a grant to any charitable institution. The resolution authorising the directors to give the grant to the new hospital was, notwithstanding what the chairman said, moved and seconded and put to the meeting, and passed by a large majority, but the chairman said it was not a motion the directors would be justified in putting into effect. It was, he said, impossible to carry out the views of the large majority, having regard to the opposition that had been evidenced in the meeting.

Death of Mr. John Dundee, L.R.C.P. & S. Edin.

I regret to announce the death of Mr. John Dundee, who was for several years dispensary medical officer of Carnmoney, near Belfast. Mr. Dundee, who was educated at Queen's College, Belfast, became a Licentiate of the Royal Colleges of Surgeons and Physicians of Edinburgh in 1869. In 1882 he succeeded his father, who was the original dispensary medical officer of Carnmoney, appointed by the Local Government Board, and he discharged the duties of the office most satisfactorily until three years ago, when he contracted influenza, and continued to work on until symptoms of his fatal malady — phthisis — developed, which compelled him in 1895 to resign his appointment. He went abroad for his health last year, but

Hosted by Google

was too weak to travel this season. He gradually got lower and died on Feb. 14th at his residence, Hillmount, Carnmoney, County Antrim, and was buried on Feb. 16th, a very large concourse of his former patients and friends being present. Mr. John Dundee was very greatly respected in his district. Naturally of a retiring disposition, he was most attentive to his patients, and it was probably owing to his extreme conscientiousness in looking after the poor in his locality that he contracted the disease which led to his untimely death. His brother, Dr. Isaac Dundee, was appointed dispensary medical officer in his place in August, 1895.

Feb. 15th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Marseilles and the Plague.

THE Municipal Council at Marseilles has begun to understand that it is a difficult matter to make strict hygienic regulations which shall not interfere with the interests of one class or another. At the first announcement of the outbreak of plague in the East there was some fear of street rioting if any infected merchandise should enter the port of Marseilles. Later, however, the inhabitants began to perceive that their commerce would suffer. They learned from the daily press that Europeans had but little to fear from the epidemic as a contagious disorder, that the bacillus plague was easy to destroy, and that the arrangements for disinfection organised at Marseilles were working admirably. Then they began to be less terrified, and though no one cared to avow the sentiment publicly complaints were generally made about the interference with trade resulting from quarantine. The mayor asked for a relief fund of 20,000 fr. for the water-side labourers who had lost their ordinary work of unloading cargo from the East, and the Municipal Council also asked that the decree prohibiting the entry of any merchandise into France except that coming by an ocean or Channel port should be altered, and that no French port should be allowed to receive merchandise from any source, so that other ports should not be favoured at the expense of Marseilles. The Prefect refused to accept this proposition. The town of Marseilles also demanded a special delegate to the Venice Conference, and has even nominated him in advance.

The Evasion of Quarantine.

The first application under the law concerning false declarations has been made at Algiers in the case of the captain of the *City of Edinburgh*, who arrived at Algiers saying that he came from Port Said. He declared upon oath and in writing that he had not come from any infected Indian town, but it has been proved that he came from Karachi and had undergone disinfection at Port Said.

The late Dr. Bourgoin.

We have to regret the death of Dr. Bourgoin, which took place this week. He was Professor at the École Supérieure de Pharmacie and had been formerly attached to the Faculty of Medicine. He was a member of the Academy of Medicine and had written many classical works, notably on Galenical Pharmacy. Three years ago he was elected Deputy for the Ardennes, and it was expected by the profession that he would champion the cause of medical science in the Chamber; but upon a vote being proposed for the sum of 140,000 fr. to meet the expenses of biological laboratories he, with one other Deputy—also a medical man—were the only two found in opposition to the grant.

The Paris Medical Societies.

At the Academy of Medicine the question of corsets has been to the fore. M. Laborde opened the discussion and illustrated his remarks by x ray photographs and the exhibition of a hygienic corset. M. Lucas-Championnière, however, said that the corset in question was nothing but an abdominal belt, and condemned it on the grounds that its constant use enfeebled the muscles of the abdominal wall. At the Surgical Society an interesting discussion has taken place lately on the surgery of the lung and the means of avoiding pneumothorax when it is necessary to open the pleura. M. Tuffier and M. Hallion have made some experiments upon animals. They propose to use a tube inserted into the trachea, and having an outer covering of indiarubber which can be dilated and made to plug the larynx. The lungs can then be artificially dilated by means of the tube, sufficient pressure being employed to prevent the layers of the pleura becoming separated during respiration. M. Quénu said that he preferred simple tracheotomy, the danger of which he considered to be exaggerated. M. Delorme averred that it is only necessary to advise the patient to cough, when the lung will be seen to again become distended.

The Syphilitic Infection of a Wet-Nurse: a Strange Medico-Legal Point.

A recent judicial decision has formed the text for a discussion at the Society of Legal Medicine. It has been decided at a Paris law court that if a nurse contracts syphilis from her nursling she has a right to recover damages from the father and mother of the child. The nurse in this case had contracted syphilis which she had not only given to her own child, who died, but also to her husband. The child who had caused all the trouble had no signs of syphilis at birth; these only appeared later, and it was only then that the nurse became infected. Neither the father nor the mother of the child had any signs of syphilis, and both declared that neither of them had ever had it. The court usually in such case orders damages to be paid to the nurse, but in this case it declared itself unable to decide and called Professor Fournier to clear the matter up. He gave it as his opinion that the parents had no visible signs of syphilis and that the child had signs of hereditary syphilis, therefore the important point was to prove the *bona fides* of the parents. The tribunal did not condemn the parents, but recognised that the nurse had suffered damages. They decided that the responsibility of the father was doubtful, because it was possible that he was not the real father. As for the mother, if she were blameable her fault could not make her husband pecuniarily responsible, for by French law the husband is not responsible for debts which his wife may contract *without his authorisation*. As it was obvious that no one was to blame there was no possibility of anyone getting damages, and the luckless nurse has every reason to remember the proverb, *Summum jus summa injuria*.

Dr. Hutinel, well known for his writings on the diseases of children, has just been made Professor of Medical Pathology at the Paris Faculty of Medicine.

Feb. 15th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Austrian Medical Chambers.

AS I have frequently had occasion to mention the Austrian Medical Chambers (*Aerztekammern*), some account of their organisation and functions may perhaps be of interest to the readers of THE LANCET. There are, in all, nineteen medical chambers in Austria, distributed as follows:—In Bukowina, Dalmatia, Carinthia, Krain, Moravia, Silesia, Upper Austria, Salzburg, and Styria, one each; in Galicia and Lower Austria, two each; and in Istria and Tyrol, three each. Every medical man is obliged to report himself and notify certain particulars to the chamber for the province or district in which he happens to reside. The powers of the chambers are not very extensive; they discuss matters relative to the general interests of the medical profession, they are expected to uphold its privileges and influence, and the courts of law are entitled to ask the chambers for expressions of opinion in special cases. Each chamber consists of at least nine members, who are elected by the medical men of the province or district, and each chamber has a president, a vice-president, and a council of honour composed of from three to seven members. The council of honour has to decide questions of ethics, disputes occurring between medical men, and complaints of various kinds; it is also empowered to take proceedings against medical men who are guilty of professional misbehaviour, and may sentence them to pay fines not exceeding £20. That is the full extent of the power of a chamber, and the medical men whom it has censured or fined have the right of appeal to the law courts. Their powers being so limited it is not surprising that the chambers have but little influence and that the majority of the medical profession consider that they ought to be re-organised and invested with greater authority.

Medical Aid Societies.

The rooms of the Medical Society have never been so crowded as on Feb. 9th, when about 1000 medical men from

Hosted by Google

all quarters of Vienna attended a meeting which was held for the purpose of protesting against the Government proposal to make insurance against sickness obligatory on employers and tradesmen. Although it may be impossible to prevent the measure passing into law, yet it was most satisfactory to find that the medical men are so unanimous in their opposition to the scheme. The President (Dr. Heim) in his opening address read letters approving of the objects of the meeting received from the medical chambers of Moravia, Istria, Bukowina, and Silesia; he also submitted a resolution proposed by Dr. Beer to the effect that medical men all over the country should enter into an agreement not to hold any appointment in connexion with the medical aid societies composed of employers and tradesmen. The first reporter, Dr. Scholz, referred to the numerous associations formed for the purpose of supplying medical aid at low rates, not only to the poor, but also to well-to-do patients, and he quoted statistics showing that, according to the conditions of medical practice which either actually exist or may be expected very soon, it is inevitable that only one medical man in six will be able to make a livelihood. He reminded his hearers that they were in duty bound to refrain from intensifying the hardships of the situation by unprofessional competition and by making visits for each of which they would receive a penny. He was of opinion that every medical man should be employed by the State and that the profession should be efficiently organised. Dr. Herz presented a highly interesting report on the evils which the present system of medical aid inflicts both on the profession and on their patients. He said that the Government proposal to establish medical aid societies among the middle classes will be the ruin of the medical profession, for medicine cannot be conscientiously practised except by persons who acknowledge the paramount obligations of morality and honour, but needy practitioners suffering from the stress of competition and inadequate remuneration will be only too likely to disregard ethical considerations. The present system of treating club members is objectionable, for it leaves the patient no choice in the selection of his adviser; moreover, no medical man can make two hundred diagnoses in a day, and in hurrying through so large a number of visits it is impossible to give the requisite attention to individual cases. He recommended the introduction of the "free choice" system which is in force in Berlin, and denounced the proposal that employers and tradesmen should receive medical treatment at the same rates as the working classes. In the result the following resolutions were unanimously adopted: (1) the system under which members of clubs and friendly societies combine to obtain medical attendance is opposed to the interests both of the patient and the medical officer; (2) the proposal to extend the principle of insurance against sickness and to render it compulsory on employers of labour and tradesmen will have a disastrous effect on the medical profession; and (3) the "free choice" system under which patients have the option of selecting their medical attendants is preferable to the existing method.

The Serum Diagnosis of Enteric Fever.

A medical paper claims for Professor Max Gruber priority as the discoverer of the serum diagnosis of enteric fever. The actual fact is that Gruber's articles on the subject appeared in print before Widal's, but the latter has the merit of having proved that the blood of patients affected with enteric fever furnishes a serum which yields a reaction, whereas Gruber applied an agar-culture for this purpose. We, therefore, owe the practical application of this method to Widal and the idea to Gruber, and the process may for this reason be appropriately called the Gruber-Widal reaction.

Pemphigus Vegetans.

At the last meeting of the Medical Society Professor Neumann exhibited a case of Pemphigus Vegetans. In the inguinal and anal folds there were reddish and white efflorescences about the size of a lentil and also moist patches. The patient suffered from dyspnœa, increased temperature, and emaciation. The affection of the skin had been increasing for some weeks and there are now symmetrical papillary protuberances from which there comes a viscid and purulent discharge of a reddish colour. The disease was first described by Neumann and forty cases have been recorded up to the present time. The prognosis is very bad, a single vesicle being a sufficient indication of a fatal result, which, as a rule, occurs within nine months. The histological changes arise in the epidermis and the upper layer of the cutis. Profuse suppuration takes place in the stratum spinosum or undermost layer of the epidermis, elevating the horny layer, the papillary bodies become enlarged, the lymph vessels and bloodvessels become dilated, the hair follicles are obstructed, and the cells of the connective tissue contain pigment.

Professor Schroetter.

Professor Leopold Schroetter, chief of the third medical clinic of the General Hospital, celebrated his sixtieth birthday last week. Professor Schroetter was for many years assistant to Skoda; he subsequently devoted himself to laryngology and published the well-known "Vorlesungen über Krankheiten des Kehlkopfes" (Lectures on Diseases of the Larynx). Some five years ago a third medical clinic was established and he was promoted to be ordinary professor and director of this clinic. For many years he advocated the founding of an asylum for patients affected with pulmonary tuberculosis and his project is now to be realised. On the occasion of his sixtieth birthday a pamphlet was printed containing contributions by Nothnagel, Leyden, and some other eminent physicians.

CONSTANTINOPLE.

(FROM OUR OWN CORRESPONDENT.)

Precautions against the Plague.

THE Superior Council of Health has seriously occupied itself in discussing the measures to be taken in the event of the plague approaching, or being introduced into, Turkish territory. The Government has, no doubt, good reasons to prepare against the invader, as thousands of pilgrims from the panic-stricken districts of India come to Mecca, the holy place of Islam. The sanitary state of the country, even in the capital itself, is far from being satisfactory. The Turkish authorities everywhere evince a good deal of anxiety and make great noise and show when the country is actually confronted with epidemics; but when the immediate danger is over they do not seem to pay the slightest attention to sanitation. These paroxysmal efforts of the authorities have been noticed in all epidemics. The Turkish Government is assured that Russia has taken all the necessary measures against the plague at the Russo-Turkish frontier; so that the Turco-Persian frontier remains to be watched. A military cordon has been appointed at Bassorah to watch the route between that town and Hanekine, the only road of communication. By order of the same council, Dr. Duca, delegate of the sanitary administration of this town to the International Council of Health in Egypt, has been appointed to Camaren, where he, together with Dr. Vaume, will watch the application of hygienic measures ot the Indian pilgrims.

Dr. Tiriakian.

Dr. Tiriakian, an Armenian physician of high repute in Constantinople, left the country some months ago for Persia. We read in the daily papers that he has been nominated member of the sanitary council at Teheran, which has only lately been formed under the presidency of His Majesty the Shah. Dr. Tiriakian is a man of great ability; while at Constantinople he filled several important posts. He was consulting physician to the great Armenian National Hospital, a member of the Armenian Board of Education, and for many years he had a seat at the National Assembly. His loss is felt by us all; at the same time we are happy to hear of his success and prosperity in Persia.

Feb. 6th.

LITERARY INTELLIGENCE. — Messrs. Archibald Constable and Co., 2, Whitehall-gardens, Westminster, have this week published Dr. Fridtjof Nansen's "Farthest North," being the narrative of the voyage and exploration of the *Fram*, 1893-96, and the fifteen months' sledge expedition by Dr. Nansen, with an appendix by Otto Sverdrup. The work is in two volumes, large demy 8vo, and contains about 120 full-page and numerous text illustrations, together with sixteen coloured plates in facsimile from Dr. Nansen's own sketches, portrait, photogravures, and maps. The price is two guineas net.—Sir William Broadbent, Bart., has a work in the press on "The Prognosis and Treatment of Heart Disease," which will shortly be published by Messrs. Baillière, Tindall, and Cox.

Obituary.

GEORGE DAVID POLLOCK, F.R.C.S. ENG.,

CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

THE profession will learn with great regret, as we have done, of the death of Mr. George David Pollock, Senior Consulting Surgeon to St. George's Hospital, which occurred at his residence, 35, Chester-square, S.W., on Sunday last, Feb. 14th, after a short attack of pneumonia.

Mr. Pollock was the second son of Field Marshal Sir George Pollock, Bart., G.C.B., G.C.S.I., the hero of the Khyber Pass and Constable of the Tower. He was born in 1817, and was, therefore, in his eightieth year. He received his medical education at St. George's Hospital and also as an apprentice to a practitioner in the country; and he was always ready to point out the value of the informal training which he received during that apprenticeship. He became house surgeon to Sir Benjamin Brodie and in 1840 became a Member of the Royal College of Surgeons of England. In 1843, through the great influence of his father and Sir Benjamin Brodie, who was much attached to him, he obtained the post of resident physician to Lord Metcalfe, appointed in this year Governor-General of Canada. The post in the colonial household was no sinecure, for Lord Metcalfe suffered from malignant disease of the face, which at length deprived him of the sight of one eye and compelled him to resign his position in 1845. Pollock returned to England with Lord Metcalfe—who died in 1846—and in that same year became a Fellow of the Royal College of Surgeons of England and was elected Assistant Surgeon to St. George's Hospital. From that time forward his name is associated with that hospital in the minds of many generations of his pupils, for he served upon the honorary staff for no less than thirty-six years. In 1852, upon the foundation of the Children's Hospital in Great Ormond-street, he was elected Surgeon to the new institution, and a little later he was appointed Examiner in Surgery for the Army Medical Staff and the Indian Medical Service. Here his kindness and geniality were found by the competitors to compare so favourably with the grimness of many of the gentlemen by whom they had previously been examined when trying for their diplomas that a notion sprang up that he attached as much importance to the demeanour and appearance of a candidate as he did to his scientific knowledge, a notion which, we need hardly say, was totally erroneous. He was a lenient examiner but a perfectly fair one.

As a surgeon Mr. Pollock was distinguished for his boldness in operating, for the care with which he examined his cases and formed his diagnosis, and for the minute attention he bestowed on every detail of the after-treatment. He was not specially original, he introduced no great advance in surgical science and left no striking work behind him; but those who followed his daily practice in his hospital could best judge of the success with which he carried out the surgical teaching of his masters—Brodie and Cæsar Hawkins. Both of these great surgeons were more celebrated for ability in diagnosis than for brilliancy in the operating theatre: Mr. Pollock was not less careful than they in his attention to diagnosis, but he shrank from no operative difficulties, and rather shone both in the greater operations and in the more delicate proceedings of plastic and ophthalmic surgery. Both in hospital and private practice his geniality of heart and his unwearied kindness endeared him to his patients, many of whom now recall the great obligations they owe to him both as a surgeon and a friend.

As a colleague no one could be more thorough and more perfectly trustworthy. A good colleague is not a man who assents to anything, but one who does not differ without cause, who will hear reason, whose judgment is based on honest motives, and who can be relied on to do what he thinks to be right. Everyone who acted with Pollock knew that he fulfilled all these conditions. He sought no selfish ends, but acted in all things with a single object—the good of the hospital or school of which he was an officer. His opinions on all matters, whether of surgery, of hospital administration, or of school management, were generally sagacious and always sincere; and he was quite ready to re-consider them if good cause were shown why he should do so. Even serious differences on important questions, such as must occur in the management of great institutions, were so treated by him as not to interrupt personal friendship; and he quitted the active service of the hospital retaining the respect and affection of all with whom he had acted.

It remains to speak of the part which Mr. Pollock took in the movement for the reform of the Royal College of Surgeons of England as President of the Association of Fellows. In this, as in all other actions of his life, his motives were the highest; he acted as he thought it his duty to act. His position and reputation as a surgeon would have ensured his early admission into the Council of the College and to its highest offices, but he disapproved of the system on which the College was then administered and would never allow himself to be placed in nomination for the Council till in the last year of his life, when he thought he saw a chance of serving the interests of reform by taking his seat on the Council; and therefore against the opinion of many of his friends he expressed his willingness to serve if elected. It was probably well for him that the constituency preferred younger candidates. But this, as well as every other incident in his connexion with the Fellows' Association, was creditable to his high sense of honour and duty and showed the indomitable spirit which forbade him to shrink from labour at an age which entitled him to repose.

Mr. Pollock's literary contributions to his science were few and consisted of certain articles in "Holmes's System of Surgery"—the subjects of which were Injuries to the Abdomen and Diseases of the Mouth, Pharynx, and Intestines—and one or two papers communicated to the learned societies. That these bodies held him in no lightness of esteem because he was an infrequent reader of papers is shown by the fact that he was President of the Royal Medical and Chirurgical Society and of the Pathological Society. He was also Surgeon-in-Ordinary to the Prince of Wales.

By Mr. Pollock's death we have lost an exponent of old-fashioned manners as well as a justly esteemed leader. The scrupulously professional attire which he invariably wore consorted well with his courtesy and dignity of demeanour, and the two formed a demonstration of his own great respect for his calling. It will probably surprise many to whom his fresh alert face was well known to learn that he had attained so great an age of seventy-nine. He married in 1850 Marianne, daughter of Mr. Robert Saunders, by whom he had five children, three of whom survive him.

A memorial service will be held on Saturday next, at 2 P.M., at St. Michael's, Chester-square.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. E. J. Lebedinski, *privat-docent* of Internal Medicine in the Military Academy of Medicine, St. Petersburg.—Dr. A. F. Prussak, Emeritus Professor of Otology in the Military Medical Academy, St. Petersburg.—Dr. Wannebroucq, formerly Professor of Clinical Medicine in the Lille Faculty of Medicine.

Medical News.

UNIVERSITY OF LONDON.—At the Preliminary Scientific (M.B.) Examination in January the following candidates were successful in the subjects indicated:—

Entire Examination.—First Division: Charles Henry Dawe, Guy's Hospital and University Tutorial College; Charles Wesley Forsyth, Owens College and private study; Somerville Hastings, Middlesex Hospital and University and University Tutorial Colleges; John Borland McVail, private study and University Tutorial College; Percy John Robbins, St. Mary's Hospital; and William Morton Robson, Guy's Hospital. *Second Division:* Charles Edwin Adams, Guy's Hospital; Richard Appleton, B.A., University Tutorial College and private tuition; Agnes Maud Brown, University and University Tutorial Colleges; Henry Butler, University Tutorial College; Herbert Melville Churchill, Brighton Grammar School; James Duncan Clay, King's College; Percy Reynolds, B.A., Yorkshire College and private study; Anna Maude Smith, Alwyne and Birkbeck Institutes; Vere Godsalve Ward, St. Bartholomew's Hospital; and Walter Perceval Yetts, University Extension College, Reading, and University Tutorial College.

Chemistry and Experimental Physics.—Joseph Ebenezer Adams, City of London School; Algernon James Beadel, Guy's Hospital and University Tutorial College; *Maud Bennett, University Tutorial College and Birkbeck Institution; *Victoria E. May Bennett, University College, Cardiff; *Lilly Alice Bilke, Carlyon College; *Alwyn Hewett Bradley, Mason College; *William Wellesley Campbell, King's College; George Arthur Charter, private study;

Hosted by Google

*George Brooke F. Churchill, Guy's Hospital and University Tutorial College; *Olive Claydon and *Anne Fenton Cleaver, University Tutorial College; William Henchman Cole, Guy's Hospital and University Tutorial College; Carey Franklin Coombs, University College, Bristol; *Edgar Winn Fox Dolman, Epsom and King's Colleges; Lætitia Nora Ede, private study and tuition; *Frederic Augustus Edmonds, Epsom and University Colleges and private study; Edgar Severn Ellis, Cheltenham Science School and St. Bartholomew's Hospital; *Julian Craig Fleming and Geo. Francis Innes Harkness, University and University Tutorial Colleges; *Frederic Rosenberg Harris, St. Mary's Hospital and private study; *Anne Elizabeth Hooper, University College, Nottingham; *Andrew Ferguson Horn, University and University Tutorial Colleges; Norris Norman A. Houghton, University Tutorial College; Lawson Jervis Hughes, Guy's Hospital and University Tutorial College; *Frances Mary Jenkin, Westfield College and Plymouth Technical School; *Lionel Capper Johnson, Owens College; Henry Arthur Kellond-Knight, St. Bartholomew's Hospital; *Ernest Thomas Kendon, London Hospital; *Reinold Frederic Korte, private study; *Charles Ernest Lakin, Middlesex Hospital, University College, and private tuition; *Alfred Lewthwaite, University Tutorial College; Charles Ernest Wheatley Lyth, Wesley and Firth Colleges; *Agnes Emma Mecklenburg, University and University Tutorial Colleges; *Helen Moore, University Tutorial College; *Mary Eva Hastings Morris, University College, Aberystwith; *William John Morrish, St. Mary's Hospital; Gilbert Phillips Mosscrop, University Tutorial College; *Harold Rundle Fitz Nattle, private study; *Herbert Harland Raw, Kingswood and St. Bartholomew's Hospital; William Arthur Rees, Middlesex Hospital, University College, and private study; George Struan Robertson, Guy's Hospital and Dulwich College; Frederick Cecil Robinson, Guy's Hospital; Charles Edward Rogers, B.A., Yorkshire College and Leeds School of Medicine; *John Bart Rous, St. Mary's Hospital; Charles Chapman Ruchton, Owens College and private study; *Charles Russ, St. Mary's Hospital and Birkbeck Institute; *Agnes Catherine Scott, Yorkshire and University Tutorial Colleges; *Edith Serjeant, private study and University Tutorial College; *Charles William Smith, private study; James Ernest Sutcliffe Smith, Owens College; *Louisa Spicer, and *Ethel Maud Stacy, University and University Tutorial Colleges; James Batson Stephens, University Tutorial College; *Emily Gertrude Stuart, University Lectures, Oxford, University Tutorial College, and private tuition; *Robert Archibald S. Sunderland, St. Bartholomew's Hospital; Alice Taylor, University College and private tuition; Andrew Telfer, B.A., private study and tuition; Louisa Graham Thacker, Bedford College, London; *Albert Edward Thomas, St. Bartholomew's Hospital; *Herbert Kingsley Ward, Mason College; Hugh Watts, Dulwich College and St. George's Hospital; Eugene Christopher Whitehead, Wyggeston School, Leicester; *Arthur Whitehead-Smith, Epsom College and St. Thomas's Hospital; *Clare Aveling Wiggins, St. Mary's Hospital; *John Thomas Williams, University College, Cardiff; Lauriston Leonard Winterbotham, Cheltenham School of Science; *Frank Herbert Wood, St. Bartholomew's Hospital and Alwyne Institute; *Maurice Dunbar Wood, Guy's Hospital; and Graham Pallister Young, University Tutorial College.

Biology.—*Anne Thompson Barnard, Birkbeck Institution; Henry Edgar Barnes, St. Mary's Hospital; *Mildred Mabel Burgess, University Tutorial College; *Brynmor Chiles-Evans, University Colleges, Aberystwith and Cardiff; *Edward Murray Clarke, University College, Cardiff; *George Thomas Collins and *Michael Abdy Collins, University Tutorial College and Guy's Hospital; Lidbrooke Frank Cope, St. George's Hospital; *James Frederick Corson, Owens College and private study; John Cyril Curtis, University College and private study; *Harold John De Brent, St. Thomas's Hospital; *Thomas Scarbrough Dudding, Oundle School and London Hospital; *John Parker Ellerington, Carlyon College and private tuition; *John Evans, University College, Aberystwith and Guy's Hospital; *Arthur Claypon H. Gray, Guy's Hospital and Malvern College; *Charles Alwis Hewavitarna, University College; *Henry Crewe Keates, Guy's Hospital and University Tutorial College; Robert Hammersley Lee, King's College; *George Bartley McKean, private study; Newton Herbert Marshall, B.A., Baptist and University Colleges, Nottingham; Arthur Francis Martin, Owens College; Sydney Wood Milner and *Frank Herbert Noke, St. Bartholomew's Hospital; *William Gibson Parker, Guy's Hospital; *Francis Baldwin Pinniger, Charing-cross Hospital; Henry William Plant, B.A., Mason College; *Frank Leslie Thomas, Guy's Hospital and University Tutorial College; *Robert Nimmo Watson, Westminster Hospital, University Tutorial College, and private study; and Herbert Gresham Wright, King's College.

* These candidates have now completed the examination.

FOREIGN UNIVERSITY INTELLIGENCE.—*Baltimore (Johns Hopkins University):* Dr. L. F. Barker has been appointed Assistant Professor of Anatomy.—*Berlin:* Dr Klemperer and Dr. Rosenheim, *privat-docenten* of Internal Medicine, have been granted the title of Professor.—*Groningen:* Dr. Wiersma has qualified as *privat-docent* of Psychiatry.—*Heidelberg:* Dr. Nissl has qualified as *privat-docent* of Psychiatry.—*Innsbruck:* Dr. Loos has been appointed Extraordinary Professor of Children's Diseases.—*Kazan:* Dr. Darkshevich has been appointed Professor of Neurology. Dr. Savchenko of Kieff has been appointed Extraordinary Professor of General Pathology.

MESSRS. GEORGE MASON AND CO., LIMITED, of Chelsea Works, Walham-green, manufacturers of specialities for invalids, write to state that they have no connexion whatever with the firm of Frederick Mason of Acre-lane, Brixton, against whom a receiving order in bankruptcy has recently been made.

THE annual general court of the governors of Charing-cross Hospital was held on Feb. 17th, when it was announced that the Lord Mayor had consented to hold a meeting on March 5th in aid of the special appeal for £100,000 to rescue the institution from its unfortunate pecuniary position.

FREEMASONRY: ÆSCULAPIUS LODGE, No. 2410.—A regular meeting of this lodge was held at the Café Royal, Regent-street, on Feb. 10th, Thomas Dutton, M.D. Durh., the Master, being in the chair. C. H. Broadhurst, L.R.C.P. Lond., M.R.C.S. Eng., was admitted to the third degree. L. H. Pegler, M.D. Edin., H. S. Lunn, M.A., M.D. Dub., W. E. Gillson, L.R.C.P. Lond., M.R.C.S. Eng., and G. Newton Pitt, M.A., M.D. Cantab., F.R.C.P. Lond., were admitted to the second degree, and E. V. White, F.R.C.S. Eng., was admitted into Masonry. There were a large number of visitors present, and the meeting was very successful. Some forty brethren afterwards dined together.

THE ROYAL FREE HOSPITAL.—The annual report of the Royal Free Hospital shows that during the year 1896 there were 1950 in-patients admitted, 1767 were discharged, cured, or relieved, and 161 died; the average residence of these patients was about twenty-four days. There were 21,660 patients and 17,332 casualty patients. With a view to avoid abuse of the out-patient department Miss Stewart, the hospital almoner, working in connexion with the Charity Organisation Society, makes inquiries into the circumstances of applicants. The total ordinary income for the year, including legacies, was £14,477, and the expenditure was £11,226. A donation of £1700 was given by Mr. John Bentley to the fund for the new buildings. Twenty-three of the students attending the School of Medicine for Women and the Royal Free Hospital became qualified during 1896; there were 159 students at the end of the year.

WIGAN MEDICAL SOCIETY.—The annual meeting of the above society was held on Feb. 5th in the Royal Albert Edward Infirmary, Mr. C. R. Graham, President, being in the chair. The following office-bearers for 1897 were unanimously elected:—President: Mr. C. T. Street. Committee: Mr. Street (President), Mr. Graham (ex-President), Mr. Mitchell Roocroft, Mr. G. H. Monks, Mr. Brady, Mr. Cowan, and Dr. Benson. Hon. Treasurer: Mr. G. H. Monks. Hon. Secretary: Mr. Wm. Berry. Mr. Damer Harrisson read a paper entitled "Brain Surgery," and illustrated his remarks by means of lantern slides. A cordial vote of thanks was accorded to Mr. Harrisson for his paper, want of time preventing a full discussion.—Mr. Hugh G. Jones showed three cases of Double Optic Neuritis and made some remarks.—Mr. Cowan showed a case of Jacksonian Epilepsy which had been considerably improved by Trephining.—Dr. Milroy showed the following pathological specimens: (1) Gangrene of Lung following Poisoning by Ammonia Liniment; (2) Gangrene of the Œsophagus with Perforation, said to have followed injury at football; (3) Dermoid Cyst of Ovary; (4) Sarcoma of Inferior Maxilla; (5) Cystic Kidney; and (6) a Gall-stone weighing 265 grains.

THE HOWARD ASSOCIATION.—At the February meeting of the committee of the Howard Association, 5, Bishopsgate Without, E.C., a resolution was adopted expressing approval of the action of the Local Government Board in deciding that pauper children shall remain as hitherto under the care of the various boards of guardians. The committee think that experience has proved that in many districts the education and boarding-out of such children may be safely entrusted to the boards of guardians and the committees of ladies whom they appoint for the purpose of exercising supervision over details, whereas the placing of the children under a new central Education Board, as suggested by some well-meaning persons, would be an experiment involving undesirable risks and dangers. The committee of the association, moreover, is of opinion that the practice of boarding-out should be extended and that there should at the same time be an increase both of the voluntary visitation and the official inspection of the children under that method of training. The committee have also invited the attention of the Earl of Elgin, Governor-General of India, to the necessity for making provision in Indian prisons for the separation of young girls from adult criminals, prostitutes, and habitual thieves.

Hosted by Google

UNIVERSITY OF CAMBRIDGE.—The third examination for the degrees of M.B. and B.C. will begin on April 27th. Names are to be sent in by April 1st. The first and second examinations will begin on June 14th. It is proposed to confer on Dr. Nansen the degree of Sc.D. *honoris causâ* on March 16th. On Feb. 11th the degrees of M.B. and B.C. were conferred on Mr. E. C. Salt, B.A., of Emmanuel, and the degree of B.C. on Mr. R. W. Wakefield of Trinity.

ALLBUTT'S "SYSTEM OF MEDICINE."—The following notice has been issued by Messrs. Macmillan and Co., Limited, to subscribers:—

"The delay in the issue of Volume II. of this important work, which the editor and the publishers regret as keenly as any subscriber can do, has been entirely due to the delay in the issue of the Report of the Royal Commission of Vaccination. Until this was in the hands of those who had undertaken to contribute articles on this subject, it was impossible for them to deal with all the facts of a complicated problem fully and authoritatively in the light of the latest knowledge and opinion. Every possible effort has been made to get these articles completed, and everything is now in the printer's hands. All the rest of the volume has been practically ready for many months, and the whole of Volume III. and the greater part of Volume IV. is already in type, so that subscribers can feel assured that so long an interval will not again elapse between the appearance of one volume and another, and that the whole 'System' will be complete within a reasonable period."

THE Rochdale and District Medical Society at a recent meeting passed the following resolutions unanimously:—"That on and after June 1st, 1897, whenever any registered medical practitioner or practitioner entitled to be registered (other than practitioners empowered by the Medical Act, 1886) either directly or indirectly issues, or sanctions, or takes part in the issuing of, any instrument or document professing to empower the holder of such instrument or document to practise, or to hold himself or herself out as being thereby entitled to practise, any part or branch of medicine, surgery, or midwifery, such practitioner shall, on due proof being given of his or her so doing, be judged by the General Medical Council to have been guilty of infamous conduct in a professional respect and his or her name shall be erased from the Register and registrable qualification taken from him or her." "Seeing that the Midwives Registration Bill would, if it became law, create an independent order of midwifery practitioners, this meeting, while anxious that the training of monthly nurses should be improved, records its emphatic protest against such proposed legislation, and determines to form a committee to watch the progress of, and oppose, any legislation such as that hitherto proposed for the registration of midwives." "That these resolutions be sent to the President of the General Medical Council, the five Direct Representatives, THE LANCET, and the *British Medical Journal*."

PLYMOUTH MEDICAL SOCIETY.—A clinical meeting was held on Feb. 13th.—Mr. J. R. Rolston showed a girl, aged fifteen years, with Hydrophthalmos and Coloboma of Lens. In the right eye the cornea measured 15 mm., and in the left eye 13 mm. In the right eye there was an irregular notching of the temporal margin of the lens and the suspensory ligament could be distinctly seen.—Mr. Woollcombe showed: 1. A man on whom he had operated three months previously for a Fusiform Popliteal Aneurysm. After intermittent pressure on the vessel just before entering Hunter's canal for ten days to establish collateral circulation the vessel was tied with kangaroo tendon and divided at the above point. The man was walking eleven miles a day and doing his work as a mason in addition. 2. A case of Ununited Fracture of Olecranon which he had drilled and brought together with kangaroo tendon four months after the original injury. The boy now (ten weeks after operation) was as strong in this arm as in the other. There was no separation of fragments.—Mr. Row showed (1) a woman with Overgrowth of Hair on Face; (2 and 3) two men with Ulceration of Tongue, one being undoubtedly epithelioma and the other, although it originated as a gumma, thought to have become epitheliomatous; and (4) the Uterus and Appendages from a girl who died after an illegal operation.—Dr. Webber showed a Sternum from a woman who died after an operation for Mammary Scirrhus, and who was found to have extensive visceral deposits. The sternum had extensive marrow infection and was about twice its normal thickness and bowed forward as in extreme emphysema. A microscopic section of the marrow was also exhibited showing its malignant nature.—Mr. Lucy showed an original Automatic Wound Retractor.

THE annual general court of the governors of the City of London Lying-in Hospital was held on Feb. 17th, when the chairman was able to announce that no maternal death had occurred in the hospital during the year.

FOOTBALL CASUALTIES.—In a match played at Wells (Somerset) on the 6th inst. between Wells and Paulton a member of the former team received a severe kick in the face, which fractured his nasal bone.—While playing a match on the 30th ult., at Forest Fach, near Swansea, between the local junior teams, a player sustained injuries in the abdomen. He subsequently gradually sank, and died on the 8th inst.—During a match played in London last week a forward player severely injured his knee.—In the first half of the English Cup Tie at Perry Barr, Birmingham, on Saturday last, between Notts County and Aston Villa, the right half-back of the Nottingham team fractured his right leg badly just above the ankle, and was removed to the General Hospital, Birmingham.

PRESENTATIONS TO MEDICAL MEN.—Mr. James H. Fergusson, F.R.C.S. Irel., L.R.C.P. Edin., L.F.P.S. Glasg., D.P.H., of Killygordon, has been presented by his friends with an address, a complete laboratory (bacteriological, chemical, and hygienic) apparatus, and a purse of sovereigns.—Dr. Wm. A. Russell, of Wingate, county Durham, has been the recipient of a valuable timepiece from the members of the Wingate and District Ambulance Class, as an acknowledgment of his services as Lecturer on Ambulance Aid.—Dr. Hugh Steven, of Codford St. Mary, Wilts, on leaving his medical district at Codford, has been the recipient of a testimonial, subscribed for by patients in each parish of his district, as a grateful recognition of many kindnesses received from him and Mrs. Steven during their residence in the neighbourhood. The presentation consisted of a dining-room timepiece, a silver plated sugar-basin and cream-jug with inscription, an illuminated address, and a list of subscribers.

THE DIFFUSION OF SMALL-POX.—The comparative freedom from small-pox which London has of late enjoyed is no longer a matter for congratulation, fresh outbreaks having occurred. In the four weeks ended on Nov. 28th last there was not a single notification of the disease in the whole of London, and in the succeeding five weeks, which brought the year to a close, there were only 3 notified cases, followed by 8 in the first four weeks of the current year. The admissions of small-pox cases to the hospital ships at Long Reach in the last three weeks of January had been 1, 0, and 7 respectively, and on the concluding day of that month there were 21 cases of the disease on board, as compared with 9 a week earlier. Last week there were other 20 cases admitted to the ships, and Saturday last found no fewer than 38 patients on board. The chief seat of the present outbreak seems to be on the south side of the Thames, Camberwell area apparently being the principal sufferer by the malady. We have become so accustomed of late to look with complacence on the weekly freedom from fatal small-pox that it is startling to hear that last week there were 2 deaths registered from the disease. Such was the case, but no statement was made as to the vaccination of either person, one of whom belonged to Camberwell and the other to Greenwich. Up to the night of the 17th 17 cases had been reported in, and removed from, Camberwell Infirmary.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Vaccination Question.

MEMBERS of Parliament continue to question the President of the Local Government Board with regard to the action, or want of action, on the part of boards of guardians for enforcing the Vaccination Acts. Mr. Chaplin's invariable answer is that the report of the Vaccination Commission in no way alters the law or relieves boards of guardians from prosecuting offenders.

The Army Medical Service.

The vote for the Medical Establishment of the Army was taken somewhat unexpectedly at a late hour on Friday, Feb. 12th, and Dr. Farquharson lost his opportunity of calling attention, as he intended to do, to several matters connected with the examinations and the treatment of medical officers after entering the service. When, however, the report of the vote was taken on Monday, Feb. 15th, he was

Hosted by Google

able to put one or two practical points to the Under Secretary for War, who undertook to give them proper consideration.

HOUSE OF LORDS.

MONDAY, FEB. 15TH.

Bubonic Plague in Bombay.

Lord Reay addressed a question to the Under-Secretary for India with reference to protective measures against this disease and with reference to the temporary employment of retired members of the Indian Civil Service. His lordship gave some account of the discoveries of Professor Haffkine and Dr. Yersin and of the results of inoculation, and with regard to retired members of the Indian Civil Service he said there were many who had declared themselves ready at any time to go and assist their brethren in India. He hoped that no hesitation would be felt by the Home Government if an appeal came from India to mobilise those reserve forces, which certainly under the exceptional circumstances now prevailing might be used effectually and without in any way dislocating existing arrangements.—The Earl of Onslow, in reply, said that Dr. Yersin had been commissioned by the Government of Bombay to procure serum for use there, and he was expected to return to the city about the end of this month or the beginning of next provided with a sufficient quantity of it. Speaking generally, the Government of Bombay considered that inoculation appeared to afford considerable protection, but sufficient time had not yet elapsed to estimate the degree of protection or how long it would continue. With regard to the other matter no retired Indian Civil servants had as yet been sent out to India, but the India Office would be prepared to receive the names of any who were willing to volunteer for this service. It did not rest with the India Office to determine whether or not they should be sent out, but their names should be telegraphed to the Viceroy, and if in the exercise of his discretion he thought their services could be made available no doubt he would act accordingly.

HOUSE OF COMMONS.

FRIDAY, FEB. 12TH.

The Army Medical Service.

Mr. Brodrick, Under-Secretary of State for War, made the following statement on this subject in introducing, in Committee of Supply, the Army Estimates—viz., "A thorny subject which we have had to deal with has been the condition of the medical department. For some time past, as the Committee is aware, we have had difficulty in procuring sufficient candidates for the Army Medical Department. Many reasons have been adduced for this, among which may be mentioned the question of rank and social condition, the examinations which were held to be conducted under less favourable circumstances for candidates from Irish and Scotch medical schools than for those attending London schools, the rate of pay in India, and the prolonged terms of foreign service. Lord Lansdowne has given the most careful personal attention to all these questions. He has received various deputations and has spared no pains to get to the root of the difficulty. His conclusion is that as regards the examinations, while every consideration should be given to eminent members of the Scotch and Irish medical schools in filling vacancies on the examination board, the board should be constituted solely with reference to the professional eminence of its members without regard to the mere fact of their coming from one part or another of the United Kingdom. The falling off of Irish candidates, not being more than on a par with the falling off of other candidates, has no special significance or importance. Lord Lansdowne has also reviewed the whole circumstances attending the present titles of medical officers, a question which appears to be closely bound up with their complaints of a lack of social consideration. The truth appears to be this. When the system of attaching medical officers to regiments was abandoned, on grounds which at the time were certainly deemed to be sufficient for the system of appointing them to stations, medical officers lost their special and close personal contact with their regimental brother officers. Attempts have been made to give them a better position—first, by ranking them with combatant officers on the recommendation of Sir Andrew Clark as representing the schools, and then by conceding composite medical and military titles carrying with them substantive rank in their own department. These concessions, though welcomed at the time by the profession, have not altogether acted as was desired. Lord Lansdowne is anxious that every consideration should be shown to the officers of this most valuable and distinguished department. He has, after communication with the India Office, been able to secure to the medical officer an increase of pay in India, and the Indian tour will be decreased from six years to five. Assistance will also be given to form medical messes at the large stations, quarters will be offered in barracks where possible, and opportunities to study on return from foreign service will be given. But none of the proposals which have been submitted to the Secretary of State for giving new forms of army rank to the medical staff appear to him desirable for adoption. He does not believe that by such titles the Medical Department will obtain the status to which their talents and professional acquirements entitle them, and anxious though the War Office is to meet the medical profession on all points, this is not one of those on which further action appears to be desirable.

Health of Troops at Home and at Gibraltar.

Sir Howard Vincent asked the Under-Secretary of State for War if he could inform the House how long had been the average station at Gibraltar of regiments of the line, if they had been generally reported on as inefficient or unfit to fight after service at Gibraltar, how many nights a week privates were as a rule on guard, and if more or less than the Foot Guards at Wellington or Chelsea Barracks; and if regiments suffered in greater proportion there from disease than at home.—Mr. Brodrick replied that the average stay of the last eleven battalions at Gibraltar had been three years. The reports on regiments leaving Gibraltar had not been such as were indicated in the question; the Foot Guards in London as a rule had one night out of bed on guard in every eight nights, and the guard duty at Gibraltar was about the same. The health statistics show that in the last ten years the admissions to hospital at Gibraltar were 39 per 1000 less than in the United Kingdom, the number of men discharged as invalids were 8·71 per 1000 at Gibraltar, while those discharged in the United Kingdom were 16·34 per 1000, and the number of deaths at Gibraltar were 4·90 per 1000, against 5·20 in the United Kingdom.

MONDAY, FEB. 15TH.

Hospital Accommodation at Sierra Leone.

Mr. Powell Williams, replying to a question on this subject put by Mr. Bill, said that the question of where the additional hospital accommodation for Sierra Leone shall be located was still under consideration. An increase to the garrison of Sierra Leone was provided in the Estimates, and additional hospital accommodation would be required for the force thus added.

Private Lunatic Asylums.

Mr. Field asked the Secretary of State for the Home Department whether any regular inspection regarding the management of private lunatic asylums and their inmates was made and reported on by responsible Government officials; and whether the system and working of private lunatic asylums would be inquired into and reported to the House.—Sir Matthew White Ridley replied that all licensed houses were regularly visited by the Lunacy Commissioners—those in the metropolitan area six times a year, and those outside that area twice. The latter are also visited six times a year by three justices and a medical practitioner appointed for the purpose by quarter sessions. He was not aware of any necessity for such an inquiry as the hon. Member suggested.

Venereal Disease in the Army.

Mr. Jeffreys, speaking on the report of the vote for the medical establishment of the army, said he wished to call attention to the terrible increase of venereal disease in the army, notwithstanding the advance in scientific knowledge and the great ability of our medical men. In India there was a tremendous increase in the disease, and a captain told him that a number of his men had to be carried on board ship wrapped up in cotton-wool, so wretched was their condition. He wished to ask the Under Secretary whether the Medical Department could not do something to stop this terrible state of things. It had been complained that our army was too small in point of numbers, but surely it would be better instead of increasing the numbers to try to stop this disease, which incapacitated so many of the men now in the ranks.—Mr. Brodrick, in reply, said that he was afraid that the evil lay, not at the door of the medical officers, but at the door of this House. He would not go back to the whole history of the abandonment of the Acts in 1882, but it would be in the recollection of Members that in 1893, in deference to strong expressions of opinion in Parliament, the Council in India was called upon to re-consider the Cantonments Acts, and these Acts were done away with in that year. Since then it appeared from the statistics there had been a very rapid and serious development of the worst forms of the disease. As to the figures, it was a mistake to quote 400 or 500 per 1000 as the number constantly sick. These figures represented the admissions to hospital during the year. It was to be hoped that not nearly so large a proportion of the army as had been suggested were unable to go on parade at the same time. However, the facts disclosed had constituted so serious an evil that the Secretary of State for India had found it necessary to appoint a departmental committee, and he hoped that the report of this committee would be in the hands of Members before very long. He would only add that the matter was one which must engage the serious attention of anybody who had to do with the military organisation of the country.

TUESDAY, FEB. 16TH.

Vaccination Prosecutions.

Mr. Thomas Bailey asked the Secretary of State for the Home Department whether his attention had been called to the fact that Frederick Pearse of 65, High-street, Andover, had been prosecuted sixty-three times for non-vaccination of his children, and had paid upwards of £42 in fines and costs; and that, notwithstanding the unanimous recommendations of the Royal Commission on Vaccination against repeated penalties, the said Frederick Pearse was committed to Her Majesty's prison on the 10th inst., in default of payment of a further fine; and whether he would consider this case with a view to the release of the prisoner.—Sir Matthew White Ridley replied that his attention had been called to the case, but he could see nothing in the facts stated to justify interference on his part.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BARNARD, HAROLD LESLIE, M.B., M.S. Lond., F.R.C.S. Eng., has been appointed Surgical Registrar of the London Hospital.

BENNET, C. J., M.R.C.S., has been re-appointed Medical Officer of Health by the Fairfield Urban District Council.

COLBORNE, H., M.R.C.S., has been re-appointed a Medical Officer to the Hastings Dispensary.

COLEMAN, PERCY, M.B., B.S. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the Essex and Sunday School Union Convalescent Homes, vice W. Maine, resigned.

CRAWFORD, A. D., M.B., C.M. Glasg., has been appointed Medical Officer and Public Vaccinator for the Maxstoke and Coleshill Sanitary Districts.

CROOKS, JAS., M.D., C.M. Toronto, L.R.C.S. Edin., has been appointed Medical Officer for the Eighth Sanitary District of the Lexden and Winstree Union, vice H. D. Palmer, resigned.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.). City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (23rd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (24th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (25th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.). St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.)

FRIDAY (26th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (27th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (22nd).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Victor Horsley: Traumatic Neurasthenia.—Mr. Hurry Fenwick: Twenty Lumbar Nephrectomies.

TUESDAY (23rd).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. T. S. Ellis: On some Points in the Surgical Physiology of the Foot.

WEDNESDAY (24th).—HUNTERIAN SOCIETY (London Institution, Finsbury-circus).—8 P.M. Mr. Victor Horsley: Torticollis and its Treatment. (*Hunterian Lecture.*)

DERMATOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND (20, Hanover-square, W.).—5 P.M. Papers:—Dr. Pye-Smith: Varicella Bullosa.—Dr. Stowers: Antecedents of, and Sequel to, a Case of Paget's Disease of the Nipple.—Mr. G. Pernet: Recurrent Herpes Zoster, with remarks on Etiology.—Dr. D. Walsh: X Ray Therapeutics in Skin Diseases. Cases: Dr. Payne: (1) Arsenical Keratosis; (2) Pityriasis Rubra.—Dr. T. D. Savill: (1) Raynaud's Disease; (2) Lichen Planus; (3) (?) Lichen Acuminatus. Also cases by Dr. Abraham and others. Dr. Walsh: Dermatitis and Obliterative Phlebitis.

FRIDAY (26th).—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. The following cases will be shown:—Dr. S. Coupland: Case of Multiple Subcutaneous Nodules and Bony Growth from the Skull.—Dr. St. C. Thomson: Case of Blood Tumour of the Auricle occurring spontaneously.—Dr. A. Wilson: Case of Dual Consciousness. And other cases. Patients in attendance at 8 P.M.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (22nd).—LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Dr. E. Law: Examination of the Throat and Nose.

ROYAL COLLEGE OF SURGEONS.—5 P.M. Dr. E. H. Starling: The Changes in the Circulation consequent on Heart Failure. (Arris and Gale Lecture I.)

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Mr. A. Wynter Blyth: The Law Relating to the Supervision of Food Supply.

SOCIETY OF ARTS.—8 P.M. Mr. C. F. Cross: The Industrial Uses of Cellulose. (Cantor Lecture.)

TUESDAY (23rd).—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Melancholia and Hypochondriasis.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Abraham: Psoriasis.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Dr. D. Grant: The Diagnosis and Treatment of Diseases characterised by Discharge from the Ear.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Gowers: Lecture.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street).—4 P.M. Mr. E. Cotterell: Cases Illustrating the Surgery of the Nervous System.

ROYAL INSTITUTION.—3 P.M. Prof. A. D. Waller: Animal Electricity.

WEDNESDAY (24th).—LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-street, W., 4.30 P.M., Prof. A. Wynter Blyth: Construction of Dwelling Houses.

HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Dr. Fowler: Clinical Demonstration in the Wards.

ROYAL COLLEGE OF SURGEONS.—5 P.M. Dr. E. H. Starling: The Changes in the Circulation consequent on Heart Failure. (Arris and Gale Lecture II.)

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—2 P.M. Mr. A. Taylor (conducted by): Inspection and Demonstration in the Parish of St. George's, Hanover-square (number limited).

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.)—Mr. Paget: Surgical Cases.

SOCIETY OF ARTS.—8 P.M. Sir H. Trueman Wood: Reproduction of Colour by Photographic Methods.

THURSDAY (25th).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: On the Clinical Significance of Proteid Substances in the Urine of Disease.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. J. Hutchinson: Clinical Lecture.

SOCIETY OF ARTS.—8 P.M. Prof. J. A. Ewing: The Mechanical Production of Cold. (Howard Lecture.)

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Mr. A. Wynter Blyth: Sanitary Laws and Regulations Governing the Metropolis.

ROYAL INSTITUTION.—3 P.M. Mr. J. W. Gregory: The Problems of Actic Geology.

FRIDAY (26th).—LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Examination of Air, Soil, and Water.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Mr. St. G. Reid: Methods of Bacteriological Diagnosis (illustrated by lantern demonstrations, &c.).

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Mr. Gunn: Inflammatory Affection of Optic Nerve, &c.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

"LANTERN LECTURES."

To the Editors of THE LANCET.

SIRS,—If "Hygienist" will communicate with me I will give him the information he requires about slides and lanterns for lectures on hygiene and ambulance work. I am, Sirs, yours truly,

WILLIAM EASBY, M.D. Brux.

Westgate, Peterborough, Feb. 15th, 1897.

To the Editors of THE LANCET.

SIRS,—"Hygienist" can obtain full particulars as to hire or purchase of lanterns for lecturing from Messrs. Newton and Co., 3, Fleet-street, Temple Bar, who also have a large supply of lantern slides illustrative of hygiene; from Mr. Walter Tyler, 143, Waterloo-road, S.E.; or from Mr. Luscombe Toms, 78, Queen Victoria-street, E.C., among others. The use of oil or lime light for the lantern is a matter of importance, depending on the presence or otherwise of gas-fittings in the lecture-room and the experience of the operator. If, when "Hygienist" has applied for details to either of the above firms, I can give him any further advice or assistance I shall be pleased to do so.

I am, Sirs, yours truly,

The Lindens, Putney, S.W., Feb. 15th, 1897. J. GAY.

"THE UNQUALIFIED ASSISTANT."

To the Editors of THE LANCET.

SIRS,—The readers of the THE LANCET will have no difficulty in recognising that your correspondent "A Practitioner" (THE LANCET, Jan. 9th, 1897, p. 148) is but poorly fitted for the *rôle* of reformer either in the medical or any other profession. A more ample acquaintance with historical facts would, granting his capacity to profit from the study of what might tend to extend his power of usefulness, soon convince him that beneficent changes in any direction are not effected by exhibitions of questionable taste or a pyrotechnic display of uselessly harsh expletives. In order to bring him, if only approximately, to a reasonable frame of mind I admit that it would be much better if there were not any unqualified assistants. It also would add to the dignity of the medical profession if some of its members were not, let us say occasionally, guilty of drunkenness, wife-beating, fraud, and neglect. Some have even forgotten themselves so far as to find themselves landed in the criminal dock and convicted—whether rightly or wrongly I leave to "A Practitioner" to decide—of the offences of forgery or criminal abortion. It is sad that such things should occur to mar the fair fame of the noble profession to which "A Practitioner," by dint of unexampled energy, no doubt has succeeded in entering. But, unfortunately, they *do* occur, and to level-headed men do not furnish a pretext for miscalling the *whole* of its members, but rather for feelings of sorrow for poor human nature, its weaknesses and innumerable temptations, through which only the morally strong and prescient can safely steer. It does not necessarily follow that the young man who has wasted or lost for a time his opportunities to master the intricacies of medicine and surgery will, with the aid of the lessons of experience, continue indefinitely to fritter away his time. In a no inconsiderable number of cases students who have wasted their time at college have pulled themselves together, studied hard, qualified, and become useful members of the profession. I know some of that ilk who are now probably as highly qualified and as competent surgeons as your correspondent. On the other hand, how many medical men who were brilliant students have filled the inebriate's grave or misconducted themselves in such a way as to irretrievably blast their career? The fate of the individual, like that of existing social conditions, is inexorably determined by the influence of environment, and if "A Practitioner" wishes to shine as a reformer and extinguish the unqualified assistant he will win greater sympathy in his crusade by treating him with at least some consideration than by ransacking the dictionary for epithets with which to express his obviously ungovernable contempt. Judging from your correspondent's tone he is slightly afflicted with egotism and would have your readers to infer that he is possessed with a monopoly of the love of hard work. He is quite welcome to the flattering self-unction and also to his evidently strong desire to pose as a caustic critic, but I have found that these qualities are not infrequently characteristic of anonymous medical mediocrities who, incapable of otherwise distinguishing themselves, spend their irritatingly ample leisure in penning what cannot by any stretch of the imagination be regarded as either useful, instructive, or ornamental. Of course I am not insinuating that "A Practitioner" comes under this category. Far from it; and I take this opportunity of paying a tribute to his remarkable powers as a writer and dialectitian. I will even go so far as to afford grounds for my respect for the argumentative capacity of "A Practitioner." In one part of his letter he refers to unqualified assistants as "gentlemen," and later designates them as "good-for-nothing idlers." I was not aware, until "A Practitioner" focussed the beams of his transcendent genius on the pages of THE LANCET, that a gentleman could be a good-for-nothing idler. But perhaps your correspondent will favour us with an explanation in your next issue, and still further enhance his reputation as a critic of unqualified assistants and their employers by liberally interlarding his composition with as many adjectives as he can conveniently interpolate in order to give extra polish to the brilliancy of his style. By-the-bye, he expresses surprise that no one has anticipated him in his noble work of "purifying" the profession. He badly wants help, I admit; but I am afraid he will have all the glory to himself, for the majority of practitioners are too busily engaged attending to their duties or are too much impressed by the imperativeness of the time-honoured maxim of "mind your own business" to compete with "A Practitioner" in the elucidation of such portentous themes as "fundamental moral objections."

I am, Sirs, yours faithfully,

ONE OF THE "DAWDLERS."

S. B. H.—(1) It is more strictly correct to write on the card Mr. ——, M.D.Brux., but the other method is very commonly followed. Our correspondent will find in THE LANCET of Aug. 17th, 1895, an exposition of our views. (2) We know well the disabilities of the London student, and hope that soon a remedy will be devised for them. (3) Durham.

IMPROPER PUBLICITY.

A CORRESPONDENT has forwarded us a copy of *Brighton Society*, which contains an open letter to a local medical man. We agree that the publication of such details concerning the merits of a professional man in a lay paper is regrettable. But probably to no one will the silly effusion be more offensive than to the practitioner who is its unhappy victim.

"HYPODERMIC MEDICATION."

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent "Regular Reader" in THE LANCET of Feb. 6th, I can recommend Messrs. Allen and Hanburys' Hypodermic Syringe. Having to give about 400 injections in a year I have used several different instruments, and I can give favourable testimony to the one named in the following respects:—I used one of them during nearly the whole of 1896 daily without anything going wrong with it and without a mishap of any kind. I have just had two more needles fitted to the screw tops, but otherwise the instrument is as good as the day I got it, apparently. This example has the set of the needle to screw into the top of the barrel, and this is an advantage over other appliances that are merely pushed or socketed on, for the reason that the needle section is quite firm, not wearing loose with constant use, never leaking, easily unfastened, and also because it does not force off on pressing the piston sharply, as when one rinses the barrel out with water after use. If the needle is accidentally forced out either into a vessel or otherwise a needle is done for, as many users must have experienced. The piston arrangement ensures never failing equability of resistance, and remains constantly lubricated, and on the whole sterilising can be carried out quite easily and effectually. Some instruments are now made for sterilising chiefly and have little to recommend them in other respects. With ordinary cleanly precautions, and by sterilising very occasionally, I have had no untoward effect follow the use of an Allen and Hanburys' syringe after some 400 applications of it, using the same instrument and the same needles. If sensible asepticity is observed, and a good rinsing with water before and after use, there will be little to trouble about. In reply to the second question, tabloids are certainly the best form of hypodermic medication. They are convenient to store and handle, they will keep a long time while solutions soon go wrong, they ensure uniform dosage, and, when dropped into the barrel of the instrument after water has been drawn in they are the most expeditious and all-round satisfactory form. I find Burroughs, Wellcome, and Co.'s the best, being uniform in dosage and more readily and completely soluble.

I am, Sirs, yours faithfully,

Buckhurst Hill, Feb. 6th, 1897. HAYDN BROWN.

M.B., F.R.C.S.—We fear that nothing can be done. The dissemination of such circulars does not constitute "infamous conduct in a professional respect," and would not be punished by the General Medical Council.

MR. CRITCHLEY, PHILANTHROPIST.

THE *Bristol Times* of Feb. 12th contained the following paragraph:—

> "An inquest was held at Stroud yesterday on the body of Mary Smith, an elderly woman, wife of a carpenter, who died after a day's illness on Tuesday evening. It appeared that she had suffered from heart weakness and stomach trouble for a long time, and that she had taken medicine and used ointment supplied by a man named Critchley, who was neither doctor nor chemist. The ointment was rubbed in over deceased's heart on the day of her death. Critchley was called as a witness. He said he had no qualifications and did not profess to be a medical man. He was a philanthropist, though he made small charges for the medicine and ointment in some cases. A doctor, who was called in after death, said the medicine and ointment were innocuous. The jury returned a verdict of 'Death from natural causes,' adding that a medical man ought to have been called to deceased."

It is not our idea of philanthropy to step between a dying woman and proper medical advice with a potion and an ointment, however innocuous. Mr. Critchley is recommended to seek another outlet for his overflowing love for distressed humanity before he gives a coroner's jury an opportunity of censuring him or worse.

Dr. Harold N. Moyer is thanked for his communication.

"DR. RENTOUL'S EXPENSES FUND."

To the Editors of THE LANCET.

SIRS,—The following is a second list of subscriptions to the above fund. May I ask intending subscribers to send their donations at once and allow the fund to be closed at an early date?

I am, Sirs, yours faithfully,

"ANTISEPTIC MIDWIFERY."

To the Editors of THE LANCET.

SIRS,—From the letter of Mr. J. J. Harding in THE LANCET of Feb. 13th and from other letters which I have read I regret to find that a sentence in my address on this subject is misleading. It is that quoted by Mr. Harding, "Why the sublimate treatment should not be adopted in private practice as well as in hospitals I am at a loss to understand." I did not mean to imply that the sublimate is not largely employed in general practice. It would have been better had I expressed myself thus: "Why the sublimate treatment should not be *universally* adopted in private practice I am at a loss to understand." I have received a large number of letters from all parts of the country since the publication of my address from general practitioners asking me where copies of the lecture I delivered in 1887 giving instructions regarding the use of the sublimate in midwifery practice can be obtained. I do not believe that it is employed at all generally in private practice. If I am mistaken I shall be only too pleased to acknowledge my error. My opinion has been derived from inquiries among medical men I meet in consultation and otherwise.

I am, Sirs, yours obediently,

Grosvenor-street, W., Feb. 15th, 1897. CLEMENT GODSON.

Paterfamilias.—Water that has been boiled is just as suitable for drinking purposes as unboiled water. There is no necessity to boil water unless it is suspected to contain organic impurities. The chief drawback to boiled water is its insipidity and lack of briskness. As to milk, the evidence of clinical experience does not justify the belief that its nourishing qualities are altered to any important extent by careful boiling. It has been asserted that completely sterilised milk, if it is administered without a fresh food, will sooner or later produce scurvy. Milk, however, kept within ten degrees of boiling point for ten minutes is said to be free from pathogenic organisms, while it will not cause scurvy.

A MILLIONAIRE'S EXTRAVAGANCE.

THE *English Illustrated Magazine* for February publishes the following in an article entitled "The Extravagances of a Millionaire":—

> "An example of extravagance is the case of a well-known millionaire who built himself a castle in one of the Midland counties. The water of the place was pure and sufficient, but a case of scarlet fever occurring in the village at a little distance from his residence, he took a dislike to the local water supply, and at a cost of over £80,000 provided himself with a fresh supply from a distance of eighteen miles. Without children or wife, and a great traveller, he does not inhabit his own country place for more than three months in the year. Although he drinks no wine, his water is an expensive beverage. Allowing only 3 per cent. on the money with 1 per cent. sinking fund, his water costs him £50 for every day he visits his castle. This supply, it should be added, is limited to the one house. There is really no reason why it should be shared with others, for, as I have said, the local supply is ample and of good quality."

Puzzled.—The society is not one, so far as we know, which has deliberately set itself against the medical man, but the absence of wage limit condemns it in our eyes. If our correspondent will send us a copy of the rules we shall be able to answer the question more in detail. Are canvassers employed in such a way that the officer of the society lives upon patients obtained by touting from his fellow practitioners?

THE BENEFACTIONS OF JOHN BANCKS.

To the Editors of THE LANCET.

SIRS,—By two indentures, dated May 12th, 1619, John Bancks, citizen and mercer, granted to the Mercers' Company about six acres of land at Holloway, in the Parish of Islington, subject to the following conditions:—"That the wardens and commonalty of the Mercers, and their successors should, for ever, after the decease of the said John Bancks, yearly, for ever, pay and dispose all the said monies, so from time to time, to be paid and delivered to them, as aforesaid, to the purposes following ..... Also to the Company of Barber-Surgeons 20*s.* yearly to be distributed on the 11th day of May, yearly, to twelve poor householders or widows of the said Company." The Barber-Surgeons' share of the rents was about one-twentieth. These "about six acres" (as certified by the Charity Commissioners in 1821) are doubtless now covered by houses, &c. Please tell us in your "Charity" column how much is received yearly by the Royal College of Surgeons as their share of the total rental, which must amount to some thousands of pounds per annum, also how this share is distributed. Perhaps it may interest some of your readers to be reminded that John Bancks' daughter married Waller the poet.

I am, Sirs, yours faithfully,

Jan. 27th, 1897. C. J. B.

*** The Royal College of Surgeons of England is not in receipt of any money from this fund to the best of our belief. The Company of Barber-Surgeons is still in existence, and most probably receives the 20*s.* to which by our correspondent's letter it appears to be entitled.—ED. L.

GALVANIC DILATION OF EUSTACHIAN STRICTURES.

To the Editors of THE LANCET.

SIRS,—May I be permitted to point out that the "New Method of Dilating Strictures of the Eustachian Tube by Means of the Galvanic Current," which appeared in the *New York Medical Journal* of Jan. 16th, and by a rare coincidence is omitted from the Table of Contents of that journal, and is referred to in THE LANCET of Feb. 13th, is the method practised by the late Dr. W. E. Steavenson ten years ago and fully described by him in "Electrolysis in Surgery," p. 98 (J. & A. Churchill, 1890).

I am, Sirs, yours truly,

Mansfield-street, W. W. S. HEDLEY.

WANTED A CONVALESCENT HOME.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me of a convalescent home where two patients could be received for the summer months—a lady and daughter, both affected with pulmonary tuberculosis, but well enough to dine at table and to take gentle exercise. They can afford to pay from two to two and a half guineas per week, but would require medical supervision. An elevated inland situation is desirable.

I am, Sirs, your obedient servant,

Montreux, Switzerland, Feb. 15th, 1897. TUCKER WISE, M.D. Brux.

WANTED A SUGGESTIVE OPINION.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if any of your readers could give me hints for the treatment of the following case. The patient, aged four years, suffers from constantly recurring ulcers of the tongue, which commence near the tip and gradually creep over the dorsum in the form of a ridge, fusing together where they meet. The child seems irritable a day or two before they make their appearance, otherwise he is in good health. He has an attack at least every month, and this state of things has lasted since birth.

I am, Sirs, yours truly,

Feb. 15th, 1897. C. B.

"A THROAT IRRIGATOR."

To the Editors of THE LANCET.

SIRS,—A throat irrigator practically identical with that described by Dr. Leonard Wilde in THE LANCET of Feb. 13th has been in use by me for many years, and is figured at page 171 in my work on "Diphtheria and its Associates," published in 1895. The only difference is that the ball in mine contains a larger quantity of fluid—six ounces instead of three or four—and this appears to be an advantage, since this is as much as is ever likely to be necessary for an irrigation without the trouble of recharging. The instrument is manufactured by Messrs. Mayer and Meltzer.

I am, Sirs, yours faithfully,

London, Feb. 15th, 1897. LENNOX BROWNE.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Kepler Preparations.

KEPLER : SOLUTION

containing as it does cod liver oil in a state of molecular incorporation with Kepler Malt Extract, is universally recognised as superior to emulsions and similar preparations. Without offending the palate or disturbing the digestion, Kepler Solution ensures the absorption of the oil to an extent hitherto impossible. It is supplied in small and large bottles, at 1s. 8d. and 3s. each.

KEPLER : MALT : EXTRACT

is a highly concentrated preparation of the finest winter-malted barley. It contains a full percentage of diastase, maltose, albuminoids, dextrins and phosphates. Being a perfectly unsophisticated preparation, it is of supreme value both as a food and as a digester of foods. It is supplied in small and large bottles, at 1s. 8d. and 3s. each.

Burroughs, Wellcome & Co., London and Sydney.

Cable and Telegraphic Address:—"BURCOME, LONDON."

SYR. HYPOPHOS. CO., FELLOWS.

CONTAINS THE ESSENTIAL ELEMENTS of the Animal Organisation—Potash and Lime;

THE OXIDISING AGENTS—Iron and Manganese;

THE TONICS—Quinine and Strychnine;

AND THE VITALISING CONSTITUENT—Phosphorus: the whole combined in the form of a Syrup, with a **SLIGHTLY ALKALINE REACTION.**

IT DIFFERS IN ITS EFFECTS FROM ALL ANALOGOUS PREPARATIONS; and it possesses the important properties of being pleasant to the taste, easily borne by the stomach, and harmless under prolonged use.

IT HAS GAINED A WIDE REPUTATION, particularly in the treatment of Pulmonary Tuberculosis, Chronic Bronchitis, and other affections of the respiratory organs. It has also been employed with much success in various nervous and debilitating diseases.

ITS CURATIVE POWER is largely attributable to its Stimulant, Tonic, and Nutritive Properties, by means of which the energy of the system is recruited.

ITS ACTION IS PROMPT; it stimulates the appetite and the digestion; it promotes assimilation; and it enters directly into the circulation with the food products.

The prescribed dose produces a feeling of buoyancy and removes depression and melancholy; *hence the preparation is of great value in the treatment of mental and nervous affections.* From the fact, also, that it exerts a double tonic influence, and induces a healthy flow of the secretions, its use is indicated in a wide range of diseases.

NOTICE—CAUTION.

The success of Fellows' Syrup of Hypophosphites has tempted certain persons to offer imitations of it for sale. Mr. Fellows, who has examined samples of several of these, FINDS THAT NO TWO OF THEM ARE IDENTICAL, and that all of them differ from the original in composition, in freedom from acid reaction, in susceptibility to the effects of oxygen when exposed to light or heat, IN THE PROPERTY OF RETAINING THE STRYCHNINE IN SOLUTION, and in the medicinal effects.

As these cheap and inefficient substitutes are frequently dispensed instead of the genuine preparation, physicians are earnestly requested, when prescribing the Syrup, to write "Syr. Hypophos. FELLOWS."

As a further precaution, it is advisable that the Syrup should be ordered in the original bottles (4s. or 7s.); the distinguishing marks which the bottles (and the wrappers surrounding them) bear can then be examined, and the genuineness—or otherwise—of the contents thereby proved.

The Arris and Gale Lectures

ON

SOME POINTS IN THE PATHOLOGY OF HEART DISEASE.

Delivered at the Royal College of Surgeons of England on Feb. 22nd, 24th, and 26th, 1897,

BY ERNEST H. STARLING, M.D., M.R.C.P. LOND.,
JOINT LECTURER ON PHYSIOLOGY AT GUY'S HOSPITAL.

LECTURE I.

Delivered on Feb. 22nd.

ON THE COMPENSATORY MECHANISMS OF THE HEART.

MR. PRESIDENT AND GENTLEMEN,—In these lectures I propose to deal with certain points in the physiology of the heart and circulation, which are of importance for the understanding of the conditions met with in heart disease. In almost all cases of heart disease we find at some period or other in the course of the disease a hypertrophy of the muscular walls of this organ; and here, as invariably where we meet with hypertrophy of the muscle, we ascribe the hypertrophy to an increased strain thrown on the muscle or to an increased amount of work done by the muscle. We have, therefore, in the first place, to discuss the various physiological mechanisms, in virtue of which the heart is able to re-act to an increased strain thrown upon it in the carrying out of its functions.

The energy of the ventricular contraction is expended in two ways: Firstly, in forcing a certain amount of blood into the already distended aorta, against the resistance presented by the arterial blood-pressure, which itself is directly conditioned by the resistance in arterioles and capillaries; and secondly, in imparting to the mass of blood so thrown out a certain velocity. Thus the energy of the muscular contraction is converted partly into potential energy in the form of increased distension of the arterial wall, and partly into the kinetic energy represented by the momentum of the moving column of blood. The work done at each beat may be calculated from the formula:— $W = w R + \frac{wv^2}{2g}$, where W stands for work, w for the weight of blood expelled at each contraction, R is the arterial resistance or pressure, and v is the velocity of the blood at the root of the aorta. In this equation w R is the work done in overcoming the resistance, and $\frac{wv^2}{2g}$ is the energy expended on imparting a certain velocity to the blood. It will be seen that the energy expended in the second manner is almost negligeable as compared with that spent on distending the arterial wall, and thus on keeping up the mean arterial blood pressure. Thus, if we take the ordinarily accepted figures of 50 grms. of blood for the output from the left ventricle at each contraction, and half a metre per second as the velocity of the blood in the aorta during systole, and 150 mm. Hg as the pressure in the aorta, w R = 102 gram. metres of work, and $\frac{wv^2}{2g}$ = 0·64 gram metres. Even if the velocity of the blood is quadrupled, as may occur after production of hydræmic plethora, this latter amount will only be increased sixteen times, and so will not nearly approach w R. We may, therefore, neglect the velocity factor in considering pathological changes in the work thrown upon the heart. Any important increase in the work done by the heart can only be conditioned by an increase in one or both of the other two factors—viz., w and R—the amount of blood to be expelled at each stroke, and the resistance offered by the pressure obtaining in the arteries, or caused by any morbid narrowing of any of the orifices of the heart.

In almost all cases of heart disease there is an increase in one or both of these factors. Thus in the case which can be most easily imitated experimentally—viz., stenosis of the aorta—R is largely increased. On the other hand, in pure aortic regurgitation, R may be normal or slightly diminished. During each diastole, however, the ventricle is receiving blood from both sides—viz., from the auricles as well as from the aorta. If compensation occurs, the heart expels almost all the excess of blood which it has received, so that there is a large increase in the factor w. If, as is so frequently the case, stenosis is associated with incompetent valves, both w and R are increased, with a corresponding rise in the work thrown on the ventricular muscle.

Now it is found that the healthy heart is endowed to a high extent with what is known as reserve power, and will respond to largely increased demands on it by the performance of more work, so that the nutrition of the peripheral parts of the body may not suffer. The power of adaptation possessed by the heart can be well shown by imitating experimentally certain well-known pathological conditions. Thus, since the maintenance of the normal arterial blood pressure is intimately dependant on the beat of the heart, any inadequacy in the heart-pump will be at once evidenced by a fall of arterial pressure and a rise of pressure in the large veins near the heart, so that the arterial pressure will serve to indicate whether or not the heart is pumping the normal amount of blood from the venous to the arterial side. Now it is found that we can increase the resistance to be overcome by the heart to three or four times the normal amount without altering in any way the quantity of blood expelled at each beat. Thus we may put a ligature round the pulmonary artery and gradually tighten it until the lumen of this vessel is reduced to a third of its normal extent, without causing any material change in the arterial blood pressure, although, if we connect a manometer with the cavity of the right ventricle, we find that this side of the heart has to perform three or four times its ordinary proportion of work, in order to expel the proper quantity of blood into the pulmonary vessels and so into the left heart. This same power of adaptation is shown if the ligature is applied to the aorta instead of to the pulmonary artery. Instead of increasing the resistance to the outflow of blood from the ventricles, we may augment the work thrown on the ventricular walls by increasing the inflow of blood into them during diastole. This increased diastolic volume of the heart may be brought about either by pressure on the veins of the abdomen, so increasing the venous inflow into the heart, or by destroying the aortic valves and allowing regurgitation to take place from the aorta during diastole. In either case the work done by the ventricles is increased, causing a rise of mean arterial pressure in the first instance and preventing any fall of mean arterial pressure in the second instance. A large number of similar experiments may be devised, but they all teach the same lesson—viz., that within very wide limits the output of the heart is independent of the resistance to the output. Thus the heart possesses in a high degree the power of adaptation to changed conditions, which is the essential characteristic of living organisms; and we have now to see how far we can refer this power to the physiological mechanisms with which the heart is endowed.

Wherever in the higher animals one meets with marked powers of adaptation we are at once inclined to refer such powers to the regulative activity of the central nervous system. We know that the heart is intimately connected by afferent and efferent nerves with the central nervous system, and our first inquiry must be how far these connexions are responsible for the adaptive processes met with in this organ. The nerve-supply of the heart is derived from two sources: from the medulla by means of the vagus and from the spinal cord by the upper three or four dorsal nerves through the intermediation of the sympathetic system. In determining the action of these two sets of fibres on the work done by the heart we must measure their effect on w, the output, and on R, the arterial pressure. The measurement of arterial pressure can be easily carried out by connecting some large artery with a mercurial manometer and registering the excursions of the column of mercury. The measurement of output presents somewhat greater difficulties. Stolnikow and Pawlow practically cut out the systemic circulation altogether, and caused the blood from the left ventricle to traverse an instrument (current-measurer, Stromaiche) which rejected automatically the amount of blood that went through it. This method suffered from the defect that the arterial pressure is, in consequence of the absence of external resistance, extremely low, so that the heart is throughout under highly abnormal conditions. It enjoys, however, the corresponding advantage that R,

Hosted by Google

though low, is constant throughout the experiment, and the work done by the heart is therefore directly proportionate to the output. Better methods are those based upon the application of plethysmography to the heart *in situ*. We may either, as in Tigerstedt's method, employ the pericardium itself, filled with oil or air, as the plethysmograph, and register the changes in the volume of the heart by connecting the cavity of the pericardium with some form of piston recorder, or we may make use of Roy's cardiometer, a brass sphere which is applied round the heart and is filled with oil. In the latter case the changes in the volume of the heart are recorded by connecting the cavity of the cardiometer with a modification of Roy's oncograph. Useful data may also be obtained by recording directly the extent of contraction of the auricular and ventricular muscle.

Experiments carried out by these methods have led to the following conclusions: 1. On exciting the peripheral end of the vagus the heart is slowed, the diastole prolonged, and the amount of blood expelled at each systole increased. There is, however, a fall of mean arterial pressure, and the increased output is not proportional to the diminished frequency of the beat, so that the total output in any given time is less than that occurring before or after the stimulation. R and w being both diminished, the total work done by the heart is lessened. 2. On excitation of the nerves which reach the heart through the sympathetic system the heart-beat is quickened and there is very often a rise of arterial blood pressure. In nearly all cases the output in a given time is raised above normal, so that the total work done by the heart is increased. The effect of stimulation of these nerves on the output at each systole is variable, and the result of stimulation seems to depend on the kind of nerve-fibre stimulated. Excitation of certain of the cardiac branches of the sympathetic causes a constant increase in the strength of each ventricular beat, and therefore raises the output at each beat. This augmentation of the ventricular contraction may or may not be accompanied by acceleration.

In the living animal the activity of these nerves can only be evoked reflexly or by conditions which affect the medullary centres directly. Of these reflexes the most important are probably those which originate in the heart itself and are carried to the central nervous system by the sensory fibres of this organ. Thus, as Wooldridge showed, stimulation of the central ends of the nerve-fibres, which run to the ventricular walls, may act on the cardiac medullary centres and produce reflexly inhibition or acceleration of the heart's beat or on the vaso-motor centre and cause a rise or a fall of blood pressure. The afferent fibres of the heart, by whose intermediation the reflex fall of blood pressure is produced, in many animals take a separate course, as the well-known depressor nerve.

Now so far as our experiments go, they appear to indicate that all these reflex mechanisms are directed not so much to the compensation of vascular disorders by increased efforts on the part of the heart as to the sparing of the heart by the production of some reflex effect which shall counteract the original deviation. Thus a sudden rise in arterial blood pressure as is produced by a general vascular constriction would in itself tend to increase the work of the ventricles. We find, however, that every such rise of arterial pressure or resistance is accompanied by a slowing of the heart's beat in consequence of stimulation of the vagus centre. This stimulation is partly a direct effect of the high pressure of the blood circulating in the brain and partly a reflex from the walls of the heart itself. Moreover, it seems probable that any increase of resistance to the emptying of the ventricles excites the terminations of the depressor nerve in the heart, so that impulses ascend to the vaso-motor centre which depress the activity of this centre and cause dilatation of the vessels in the abdomen and other parts of the body. On the other hand, a fall of blood pressure is followed by a quickening of the heart-beat, brought about partly by inhibition of the vagus centre and partly by a reflex stimulation of the accelerator fibres. None of these mechanisms, therefore, seem to be directed for the purpose of maintaining that cardiac adaptation which is the necessary condition of compensation in heart disease; and this conclusion is confirmed by the fact that we may divide all the nerves, afferent or efferent, which supply the heart without diminishing to the slightest extent its power of compensation. After such a procedure we find, as before, that an increase of the resistance in the pulmonary artery to three or four times its normal amount does not alter the arterial pressure, the contractions of the right ventricle being augmented in force to the amount of increased resistance to be overcome. The power of adaptation or compensation must, therefore, be an endowment of the muscular tissue itself.

We have now to inquire what are the factors which condition this power of adaptation possessed by the cardiac muscle. Is it peculiar to the heart muscle or does it depend on properties common to all kinds of contractile tissue?

In every case where, in consequence of morbid conditions, increased work is thrown on the heart muscle the contraction is preceded or accompanied by an increased tension of the muscle. In aortic stenosis the increased tension is thrown on the muscle during contraction, whereas in aortic or mitral regurgitation the increase of tension is present just before the contraction in consequence of the augmented diastolic filling of the heart. Now on examining other forms of contractile tissue we find that in all cases increased tension or increased resistance to shortening of the muscle acts as an excitant or additional stimulus, in that the contraction occurring in the presence of such conditions is more powerful and often more extensive than in the unloaded muscle. In recording the contractions of skeletal muscle two methods are made use of, known as the isotonic and isometric methods respectively. In the first the muscle is loaded with a constant weight, which, in order to avoid deformation of the curve, is applied near the axis of the lever which records the muscle contraction. In the second the change of form of the muscle is hindered by making it contract against the resistance of a strong spring. The minimal movement of the spring is magnified to a large extent by a long, light lever, so that we get in this way the changes of tension in a muscle, contracting against a resistance which it cannot overcome. In the first method the tension of the muscle remains the same throughout the contraction; in the second the tension is continually changing, while the length remains practically constant. A comparison of the curves obtained from a muscle by the two methods brings out at once certain important facts. We find that in the isometric contraction the maximum tension of the muscle is attained much sooner than is the maximum shortening in the isotonic curve. Moreover, the isometric curve is flat-topped as compared with the isotonic, so that the effort of the muscle, so to speak, is more prolonged when it contracts against an insuperable resistance than when its contraction or shortening is unchecked. Now the isometric twitch is exactly comparable to the conditions which obtain in aortic stenosis. Under ordinary circumstances the ventricular muscle, after attaining a certain stage of contraction, overcomes the resistance offered by the aortic pressure, and can now shorten without any further check, as is shown by the fact that the systolic plateau of the intra-ventricular pressure curve is usually horizontal. In aortic stenosis, on the other hand, just as in the isometric contraction of the frog's gastrocnemius, the resistance to the shortening of the muscle fibres persists throughout the contraction, so that we have a quicker rise of intra-ventricular pressure to a height above normal and a persistence of this abnormally high pressure somewhat beyond the ordinary duration of a ventricular contraction. Even in the isotonic contractions of voluntary muscle an increase in the load to be lifted, within limits, augments the amount of work done during the contraction. This is estimated by multiplying the weight lifted into the height to which it is raised, and it is found that, although in most cases the height diminishes steadily as the weight is increased, its diminution is not at first proportional to this increase, so that up to a certain point the product of the two factors W and H increases with the increase in W. In a few cases it has been found that there may be even an increase in the height of the contraction with an increase in the weight to be raised.

The effect of tension in augmenting the energy of the muscular contraction is, however, much more strikingly shown if the increased tension be applied before the beginning of the contraction. Thus, if, when using the isometric method, the initial tension on the muscle is raised from 0 to 25 grms., the height of the curve increases steadily with the augmentation in tension. Heidenhain showed that the same held good for isotonic contractions and that a muscle-twitch is always higher in a loaded than in an after-loaded muscle. Moreover, this increase in mechanical effect is accompanied by an augmentation of all

Hosted by Google

the chemical processes which take place during contraction, as is evidenced by a considerable rise in heat-production found under these circumstances. This excitatory effect of initial tension seems to be common to all forms of contractile tissue, and was, in fact, studied on heart muscle before it had been established for skeletal muscle. Thus it has long been known that the apex of the frog's ventricle will not contract under normal circumstances, but will do so if its cavity is distended with normal saline at a pressure of from 45 to 50 cm. water. In this case a small mechanical stimulus is usually required to bring about the first contraction, which is then followed by a whole series of spontaneous beats. If the lower third of the frog's ventricle be isolated physiologically in the living frog by crushing a ring of tissue between it and the upper part of the ventricle it will, under normal conditions, never beat again. It can, however, as Heidenhain showed, be made to beat rhythmically by clamping the aorta, so raising the pressure in its interior and thereby the tension on the muscle fibres in its walls. Similar observations have been made on the smooth muscle of the ureter as well as on the thin-walled tube which forms the snail's heart. In the latter case the spontaneous beats may often be entirely abolished if the tension within the heart be reduced by cutting it and allowing the contained blood to escape. The spontaneous rhythmic beats may be at once brought back by raising the pressure in the heart a few mm. water by allowing a little snail's blood to flow into it.

We must conclude, therefore, that this susceptibility to tension is a general property of all contractile tissues. In many respects the effect of tension resembles that of a constant electrical stimulus, so that it is said that tension increases the excitability or is itself an excitant of contraction. The acceptance of this view, however, lands us in apparent conflict with certain other properties of the cardiac muscle. One of the chief distinctions between skeletal and cardiac muscle lies in the fact that whereas in the former the height of contraction is, within certain limits, proportional to the strength of stimulus, in cardiac muscle the contraction is always maximal and is the same whatever strength of stimulus be employed. How, then, can we compare the tension of the muscle to an electrical stimulus and speak of increased excitation by increased tension causing a greater contraction? The same difficulty, however, exists also in the case of voluntary muscle, since the beneficial effects of tension on the subsequent contraction is to be observed even when maximal stimuli are used throughout. The maximal contraction of a stretched muscle is greater than the maximal contraction of a muscle which is unextended before it begins to contract. In the case of the heart all contractions are maximal—that is to say, are not altered by strength of stimulus used. They are, however, altered considerably by the tension on the ventricular walls before and during contraction. What the exact nature of this tension effect is it is difficult to say. That, however, it resembles an excitatory effect in causing increased tendency to katabolism of the muscular substance is shown by recent experiments in Heidenhain's laboratory. This observer found that mere extension of a muscle caused an increased formation of acid in the muscle, just as occurs during an actual contraction. Moreover, as Professor Horsley has recently pointed out to me, although a short loading of a muscle increases its effectiveness, prolonged loading causes fatigue. We must, therefore, at present be contented with regarding the improving action of tension on the contractibility of muscle as a general property of all contractile tissues, leaving an explanation of this action to further investigation.

There is yet a further result of morbid conditions in the heart which we have not yet considered, and that is the dilatation of the cardiac cavities so generally met with in heart disease. Now it must be remembered that dilatation occurs under purely physiological conditions. When we speak of the existence of dilatation we mean that the residual quantity of blood in any of the heart cavities at the end of systole is increased above normal. The experiments carried out by Roy and Tigerstedt by plethysmographic methods, as well as those by Hürthle on the duration of outflow during systole, have proved that under no circumstances are the ventricles completely emptied by their contraction, and the experiments by the two investigators first mentioned have shown that the residual quantity of blood is a varying factor depending, (1) on the resistance to be overcome in the arteries, and (2) on the diastolic filling of the ventricles. The curves given by Roy and Adami indicate a constant increase in the systolic volume of the heart whenever there is a rise of arterial pressure or whenever, by pressure on the abdomen or injection of normal saline or defibrinated blood into the circulation, a rise of venous pressure is produced, with increased diastolic inflow into the ventricles.

It must not be thought, however, that this physiological dilatation is necessarily a beginning or sign of heart failure. I have already pointed out that, although the work performed by a loaded skeletal muscle during its maximal contraction is greater than that performed by an unloaded muscle, yet the amount of contraction—i.e., the height to which a lever is raised—is less in the former than in the latter case. The same thing holds good for heart muscle. If, for instance, we assume, in order to simplify the problem, that the left ventricle is spherical it is evident, as Roy pointed out, that a certain amount of dilatation will increase the efficiency of the contractions of the muscle fibres. For, whereas the length of the muscle-cells will vary directly as the radius or circumference, the tension on them will vary as the square of the radius and the amount of blood contained in their cavity as the cube of the radius. Hence as the heart becomes more dilated, although the tension on the individual muscle-cells is greater, yet a very much smaller contraction or shortening of the muscle-cells suffices to drive out the normal amount of blood than is the case in the undilated condition. In fact, here, as in skeletal muscle, with increased load, we have stretching of the muscle fibres (dilatation), diminished shortening or height of contraction, and increased amount of work done. It is evident, too, that if the abnormal strain on the heart walls is permanent the length of the muscle cells will also become permanently altered, just as—to choose the reverse example—the skeletal muscles become permanently shorter in this relaxed condition when there is a lasting impediment to their extension. It is probable that this permanent change in length is conditioned by the connective tissue framework of the muscle, whether in the heart or limbs.

We are now in a position to examine in detail the sequence of events in the two examples of lesions of the cardiac orifices which we selected at the beginning of this lecture. Supposing, for instance, that aortic stenosis is suddenly produced, as may be done experimentally, the next following contraction of the ventricles is called upon to meet an increased strain. The greater tension thus thrown upon the fibres excites them to more powerful contraction; the augmentation in the contractile power is not, however, sufficient to make up for the increased extension of the muscle fibres, so that at the end of systole there is a certain amount of physiological dilatation, the residual blood is greater than before, and the output during the systole has therefore been below normal. This diminished output is not, however, a lasting effect, for during the next diastole the normal amount of blood flows into the ventricle, so that at the beginning of the next systole the heart is overfull. This increased diastolic distension exercises a strong augmenting effect on the ventricular contraction, so that not only the power but also the extent of the contraction is increased above normal, and this increase might be sufficient to empty the ventricle to its usual degree even against the higher resistance offered by the stenosis. This would leave the heart in the same condition as it was after the application of the ligature round the aorta, so that we should have an alternation of weaker and stronger beats. As a matter of fact, on trying the experiment one finds that the increased contraction excited by the abnormal diastolic distension does not diminish the volume of the heart to its normal systolic amount, but is only sufficient to expel the ordinary quantity of blood into the aorta—i.e., that quantity which it has received in the previous diastole. This, however, is sufficient to secure complete compensation of the lesion; the arterial pressure remains at its normal height through the performance of an increased amount of work by the ventricular muscle. It is evident that this increased work would speedily result in fatigue and failure of the heart muscle were it not for the physiological regulation, which ordains that increased work performed by a muscle is followed by hypertrophy of the muscle, provided that the increase is not too excessive in amount. The exact cause of this hypertrophy has not yet been fully worked out. We know that greater activity of a muscle is followed by vascular dilatation and more plentiful blood-supply, so that there is a more

Hosted by Google

abundant transudation of lymph and supply of proteid to the muscle cells. We have evidence that a hypertrophy of any part involving not only increased growth of any individual cells, but also a multiplication of cells, can be brought about by increasing the lymph-supply. Moreover, the katabolic changes which accompany activity of muscle cause a marked rise of osmotic pressure within the muscles, which, therefore, swell up and become turgescent in consequence of imbibition of fluid (lymph) from the surrounding tissue-spaces. Activity, therefore, induces increased supply of nutritive material, especially proteid, to the constituent elements of the active cells, and thus a hypertrophy and multiplication of these cells.

As an example of another kind of lesion we may now take a case in which the mitral valves are incompetent. Here during the systole of the ventricle the blood escapes in both directions into the aorta and through the incompetent mitral orifice into the auricle. The auricle, therefore, during the succeeding diastole is abnormally distended, since the blood flowing into it from the veins is added to that which it has already received from the ventricle. The first strain, therefore, falls on the auricular wall, and here, as in the case of the ventricle. the increased diastolic tension causes more powerful contraction and a larger output of blood into the ventricle. This latter at the commencement of its next systole is therefore over-distended and contracts more vigorously, having at the same time less resistance to overcome than under normal conditions. Again, there is a partial escape of the blood back into the auricle, and this process goes on until the amount of blood expelled from the ventricle at each stroke is sufficient to send the normal amount into the aorta, in addition to the amount which leaks back into the auricles. If the aortic pressure is maintained at its normal height it is evident that in mitral stenosis the work done by the left ventricle must be increased above its ordinary amount, since a certain fraction of the work is wasted in driving blood back into the auricles. Hence the result of mitral incompetence is, first, increased diastolic dilatation of the left auricle and left ventricle, which later becomes more or less permanent; and, secondly, hypertrophy of the muscular walls of both these cavities.

It seems probable that a mere perforation of the mitral or tricuspid valves in a heart otherwise normal gives rise to very little disturbance of the circulation or in the conditions in the heart itself. Owing to the arrangement of the muscular fibres of the heart there is a strong circular band of fibres round each of the auriculo-ventricular orifices. This ring contracts with the rest of the ventricular muscle, thus acting as a sphincter. and practically closing these orifices. It is not until fatigue of the cardiac muscle sets in, or the orifices are held permanently open by development of hard connective tissue around them, that mitral or tricuspid regurgitation can occur to any considerable extent. Unfortunately there is a limit to the adaptive powers of the heart, as of all the other organs of the body. If the strain on the cardiac muscle becomes too great or too prolonged, or the reserve power of the muscle itself is diminished in consequence of malnutrition, we get failure of compensation and the appearance of all those symptoms characteristic of defective working of the heart pump. There is no doubt that cardiac muscle, just like skeletal muscle, is susceptible of fatigue, which, as in the latter, may be caused either by too great a strain on it during its contraction or by too great a stretching or distension between the contractions. If the limit of the reserve power of the heart be once overstepped every contraction of the heart is worse than its predecessor. A vicious circle is established, in which each contraction leaves a greater amount of blood in the heart than before, and the smaller amount flowing into the arteries affects the circulation injuriously, so that the supply of oxygen and fresh nourishment to the heart muscle is diminished. Without a speedy alteration of the circulatory conditions the heart fails within a few minutes, as is the case in asphyxia. As a rule, however, the primary change in the circulation causes reflexly inhibition of the vaso-motor centre and inhibition or functional paralysis of the skeletal muscles, so that a certain amount of relief is necessarily afforded to the over-distended ventricles. A constant recurrence of such condition of overstrain must lead to a steady deterioration of the contractile powers of the heart and the production of the chronic results of the failure of compensation, some of which we shall study in the next two lectures.

The Lettsomian Lectures

ON

DISEASES OF THE NOSE AND THROAT IN RELATION TO GENERAL MEDICINE.

Delivered before the Medical Society of London,

BY F. DE HAVILLAND HALL, M.D., F.R.C.P. LOND.,

PHYSICIAN TO THE WESTMINSTER HOSPITAL, AND JOINT LECTURER ON THE PRINCIPLES AND PRACTICE OF MEDICINE IN THE WESTMINSTER HOSPITAL MEDICAL SCHOOL.

LECTURE II.[1]

Delivered on Feb. 15th, 1897.

MYCOSIS FUNGOIDES.

MR. PRESIDENT AND GENTLEMEN,—On April 10th, 1895, I showed at the Laryngological Society of London a man aged fifty-two years, suffering from mycosis fungoides. In addition to numerous tumours all over the body and limbs, tumours were seen on the posterior and lateral walls of the pharynx and on the left arytenoid cartilage. The patient had complained of more or less sore-throat for eighteen months, but the speech was not affected. This is, I believe, the first case in which the larynx has been recognised as having been attacked by mycosis fungoides.[2]

RHEUMATISM.

Rheumatic affections of the nose have received but little attention. I cannot say that I have seen any cases in which I could assure myself that rheumatism was the cause of symptoms referred to the nose, with the possible exception of a few cases in which patients complained of pain at the point of emergence of the nasal branches of the superior maxillary nerve, and even in these cases the rheumatic origin of the neuritis is problematical. Freudenthal,[3] however, states that "a number of cases have come under his observation in which the symptoms of nasal rheumatism were distinct and unmistakeable. Two varieties of the disease were noted—one with visible changes in the nose and the other without such changes. The changes consisted of a swelling of the lower and middle turbinated bodies, which obstructed the breathing, and which could not be reduced with even strong solutions of cocaine. In all the cases the pain in the nose was very severe, and all were associated with attacks of articular rheumatism affecting various joints in the body. In all of the cases, too, anti-rheumatic treatment was the only one which had any effect on the nasal symptoms." The epistaxis which we occasionally see during the course of acute rheumatism is almost invariably due to the salicylate of sodium now so generally employed—at all events I can find no reference to epistaxis among the symptoms of acute rheumatism in the pre-salicylate days. One of the first to draw attention to this action of the salicylates was Dr. Greenhow,[4] who, in May, 1880, read a paper before the Clinical Society upon cases of Rheumatic Fever treated by the then comparatively new drug. "Epistaxis occurred in seven cases—in some of them repeatedly—and in more than one of them after ceasing when the medicine was intermitted it returned again when it was resumed." Dr. L. Shaw[5] has also called attention to the occurrence of hæmorrhages, particularly of epistaxis, in patients undergoing salicylic treatment. That the salicyl element is the one at fault is shown by the fact that hæmorrhages occur with salicine as well as the salicylates. Dr. Greenhow's experience of epistaxis in acute rheumatism treated by salicylate seems to have been somewhat unusual, as it occurred seven times out of fifty cases. Possibly the lessened frequency of its occurrence at the present time is due to the greater purity

of the drug now used. Epistaxis occurring under these circumstances requires no special treatment, and omission of the medicine is usually followed by cessation of the hæmorrhage. In the naso-pharynx the only condition which seems at all dependent on rheumatism is lacunar inflammation of the third or pharyngeal tonsil. I have seen several cases where this tonsil has been affected independently of the faucial tonsils, and the pain and suffering the patient has experienced have been greater than is usual in ordinary tonsillitis. I believe that in some of the cases the rheumatic poison is the cause of the complaint. In two cases it was clearly of influenzal origin. Before the days of rhinoscopy I should have been at a loss to explain the cause of the severe headache, pain referred to the back of the nose, and fever met with in these cases, but a glance in the rhinoscopic mirror shows irregular swelling of the tonsil, which is dotted over with yellowish spots.

Pharyngitis is a very common complication of acute rheumatism. It usually appears a day or two before the onset of the articular pain, but occasionally the throat is only complained of after the disease has fully declared itself. On examination the margin of the soft palate, the tonsils, and the posterior wall of the pharynx will be found of a deeper red colour than normal and somewhat swollen. Occasionally there is œdema of the mucous membrane, more especially of the uvula. Freudenthal[6] describes a benign ulceration of the pharynx which he has only met with in persons affected with chronic rheumatism and which promptly disappears under anti-rheumatic remedies. This I have not seen. In some cases the symptoms of rheumatic pharyngitis are so slight as not to be mentioned by the patient unless questioned on the subject. In the more severe forms the usual symptoms of dysphagia, pain in the ears and difficulty in speaking, are met with. The rheumatic origin of tonsillitis in many cases is now fully recognised. Lacunar tonsillitis is the form which usually occurs in connexion with rheumatism. It must be borne in mind that though cardiac lesions are seldom seen when sore-throat is the chief feature of a rheumatic attack, still, cases do occur in which endocarditis and pericarditis are met with, even when articular pains are entirely absent. In the discussion on tonsillitis at the meeting of the British Medical Association in 1889 I described a typical example of this.[7]

According to Sir Willoughby Wade[8] "tonsillitis is a primary infective disease of the lacunæ, rheumatic fever a secondary disease arising from the absorption of microbes or their products into the system." He adduces facts which point strongly to the conclusion that there is a special rheumatic bacillus, and furthar that this special bacillus may or may not be associated with those of tonsillitis. Suchannek[9] regards acute multiple articular rheumatism as an infectious disease which runs the course of an attenuated pyæmia. The infection starts in a large number of cases in Waldeyer's "pharyngeal ring," especially in the faucial tonsils. In the sore-throat different kinds of bacteria are found, especially staphylococci alone, or combined with streptococci. Their colonies penetrate from the mucous membrane into the deeper structures, fill up the lymph spaces, and pass into the circulation through erosions of the lymphatics and bloodvessels as a result of tissue necrosis. The occurrence of thrombosis is the cause of emboli and metastasis. If the micro-organisms are present in small numbers the tonsils may alone be affected; if, however, they are abundant and there exists a predisposition to joint affections, either inherited or of neurotic origin, then the symptoms of acute articular rheumatism may develop. The outcome of the connexion between the throat and the onset of rheumatic phenomena is the importance of preventing oral respiration and the removal of chronically hypertrophied tonsils. If tonsillitis occur it should be promptly treated with salicylates in the hope of thereby warding off an attack of acute rheumatism.

In some cases the rheumatic poison affects the muscles of the pharynx, giving rise to attacks of pain in the pharynx, much aggravated by swallowing; there may be no objective signs. The rheumatic origin of these symptoms is shown by their occurring in patients with rheumatic antecedents and by their yielding to salicylates. From its exposed condition, both externally and internally, and from the amount of fibrous tissue which enters into its structure, it might have been thought that the larynx would be especially subject to rheumatic affections. This, however, does not seem to be the case, and it is only comparatively recently that attention has been directed to the occurrence of a rheumatic laryngitis. Morell Mackenzie, for instance, whose text-book represents the high water-mark of knowledge of throat diseases extant at the time, though he mentions "rheumatic sore-throat," says nothing about rheumatic affections of the larynx, except the remark that it is probable that ankylosis of the crico-arytenoid joint may be due to primary synovitis, either rheumatic, gouty, or simply catarrhal. I have no doubt in my own mind, however, that in the past many cases of the kind have been misinterpreted; indeed, on looking back through my case book I have found cases which I should now class among rheumatic affections of the larynx, but which formerly I did not recognise as such. For instance, I have noticed in patients subject to other rheumatic manifestations swelling of one or both ary-epiglottic folds accompanied with considerable pain in swallowing and some external tenderness, which have speedily yielded to an anti-rheumatic treatment. If the case proceeds a little further the crico-arytenoid joint becomes involved and we get a condition of affairs such as Hirsch has described in a case I shall mention later. The form of sore-throat described by Hinkel[10] is clearly an allied condition. The patient complains of sudden pain on swallowing and there is slight elevation of temperature. The most painful spot is seated just behind the cricoid cartilage, or outside the superior cornu of the thyroid, or in the posterior wall of the pharynx. The mucous membrane is congested in a patchy way. In some cases a severe cough of a dry and painful character is met with. Freudenthal[11] takes even a wider view of the case and says that in predisposed persons the rheumatic laryngitis may be for weeks or months the only symptom of rheumatism, and it is probably for this reason that the correct diagnosis is not made.

There is one class of affection of the throat in which, though the evidence of connexion with rheumatism is somewhat weak, I nevertheless think that rheumatism plays an important *rôle*—I refer to cases of fixation of a vocal cord from ankylosis of the crico-arytenoid joint. In my book on "Diseases of the Nose and Throat"[12] I recorded two cases which came under my observation. It would perhaps be more correct to place these in the class of arthritis *a frigore*, but the line of demarkation between an arthritis arising from exposure to cold and that due to rheumatism is a very narrow one. In the first case the patient was a music-hall singer who, while staying at the seaside, went out rowing late at night and commenced singing. Next morning he had pain in the right side of the throat, with the loss of voice. When I saw him two or three weeks later the right vocal cord was in the cadaveric position and there was swelling at the base of the arytenoid cartilage. The second case occurred in the person of a medical man aged about forty years, who, while recently convalescent from influenza, went out for a ride on a windy day and had to raise his voice to make himself heard. On his return home he was hoarse and had all the symptoms of an acute laryngitis. I saw him some months after the onset; the right arytenoid was somewhat swollen and the vocal cord was fixed in the cadaveric position. As Freudenthal points out, if articular rheumatism of the larynx is associated with rheumatic affections of other parts of the body the diagnosis is easy; but if, as in the cases recorded above, the larynx alone is affected, it is extremely difficult to say positively that the affection is really of rheumatic origin. In rheumatism of the crico-arytenoid joint the patient complains of an uncomfortable sensation at the angle of the jaw, usually relieved by pressure, which frequently elicits crepitus, and the pain is increased by swallowing. Swelling round about the joint may or may not be present. Swallowing is generally easy at first, but dysphagia comes on later. The cord usually becomes fixed in the cadaveric position. Dr. A. E. Garrod[13] quotes three cases. The first is one related by Schützenberger. The patient, a young woman, died in the course of an attack of rheumatic fever from pericarditis and œdema of the lungs, and the left crico-arytenoid joint was found to contain an excess of fluid. The two other cases are recorded by Hirsch, whose first patient was a young man, aged twenty years, who during an attack of acute rheumatism complained of pain on the right side

of the larynx, which was increased by deglutition; the voice was hoarse. On laryngoscopic examination much redness and swelling over the right arytenoid cartilage, extending to the ary-epiglottic fold, was seen. The movements of the right cord were impaired. Within a week the laryngeal signs and symptoms had quite disappeared. In Hirsch's second case the symptoms and laryngoscopic appearances were very similar, but both sides of the larynx were involved. Archambault[14] in his Thesis quotes a case under Desbrousses' care. A patient who had had several local manifestations of rheumatism was attacked on the fourth day with dyspnœa and loss of voice. Nothing was seen at the back of the mouth or pharynx. The patient died, and at the necropsy, the arytenoid cartilages on both sides were found bare, but not necrosed. In the left articulation a reddish serous effusion was seen. A case recorded by Sendziak[15] is a typical example of this condition. The crico-arytenoid articulations were first affected, causing pain, dysphagia, aphonia, high fever, and prostration, followed by affections of the larger joints. I believe that many of the cases of fixation of a vocal cord of doubtful origin—and every laryngologist has met with these cases—are probably due to rheumatic arthritis, and that though the prognosis as regards life is good the voice will always be somewhat impaired; but even in this respect it is sometimes astonishing how good and strong a voice can be produced in spite of the fixation of one vocal cord, owing to the fact that the unaffected cord takes on compensatory action, crosses the middle line, and comes into almost complete contact with the motionless cord. Dr. E. F. Ingals[16] of Chicago believes that laryngeal rheumatism is often mistaken for neuralgia. He finds it occur most frequently in men and most commonly during spring and autumn. Nearly all subjects are of the rheumatic diathesis, the pains come and go in the manner characteristic of rheumatic affections, and they are benefited only by those remedies and surroundings which have proved most useful in rheumatism. A case recorded by Dr. Max Thorner[17] under the head of "Chronic Rheumatic Laryngitis and Pharyngitis" corresponds to the description given by Ingals, and I have had somewhat similar experience; the rheumatic origin of these cases is, however, rather doubtful. Before leaving the subject of rheumatic laryngitis I should like to add that cases of affection of the crico-arytenoid joint from gonorrhœal rheumatism have been recorded. Even if there were no cases reported we might reasonably expect that they had occurred, but had been overlooked, as we know that gonorrhœal rheumatism may affect any joint. Mr. Broadhurst[18] has recorded a case in which there was ankylosis of every joint in succession, and it would therefore be very curious if the crico-arytenoid joint alone escaped. Dr. Lacoarret,[19] in his very interesting paper on Acute Arthritis of the Crico-arytenoid Joint, gives two cases which deserve to be quoted in full.

CASE 1. *Reported by Libermann.*—"X——, twenty-six years of age, a soldier, who had only had some trivial maladies, was, in the course of 1872, attacked with some rheumatic pains. On April 28th, 1873, he contracted gonorrhœa; on May 15th sudden suppression of the discharge; immediately afterwards pains in joints of the shoulder and knee without articular swelling. At the end of three or four days violent pain in the laryngeal region accompanied by complete aphonia. The articular pains have ceased since the appearance of the aphonia. Violent pains in the left laryngeal region coming on spontaneously as well as on pressure. On laryngoscopical examination a considerable swelling of the left arytenoid cartilage is seen, especially at the articular part, which exhibits quite a considerable globular enlargement, over which on passing a laryngeal sound the sensation of fluctuation is clearly enough perceived. The mucous membrane covering the arytenoid is red, but the redness does not pass beyond the cartilage; the adjacent parts are quite healthy. The left vocal cord is narrower than its fellow and does not approach the middle line. When the patient pronounces the vowel 'a' it remains immobile. Examination of the chest does not reveal any pulmonary lesion. He has never had a syphilitic affection. In the presence of these lesions, and on account of the order of succession of the symptoms, I believe that I can diagnose a gonorrhœal arthritis of the crico-arytenoid articulation. Blisters over the laryngeal region, iodised opium painting over the articulation. After some days the pains disappeared, the voice returned little by little, and the patient left cured on June 30th. The laryngoscopic examination made at this time gives the following result: the left arytenoid cartilage and the crico-arytenoid articulation have returned to their normal state, but the left cord has not completely regained its size (slight atrophy of the cord) and it does not quite approach its fellow; the voice is nearly normal."

CASE 2. *Reported by Mr. K. Simpson.*—"S. H., a bachelor, consulted me for the first time on Feb. 23rd, 1888. He had had three attacks of gonorrhœa; the last occurred five weeks before. He has complained of pain and stiffness in the left knee for the last three weeks; similar phenomena showed themselves in the right knee, then in the left hip. The left thumb became equally painful and tumefied; the swelling extended over the anterior part of the wrist and over the back of the hand, and at this time these regions presented the typical appearance of an acute rheumatic inflammation. The throat symptoms had commenced three days before in the morning, with pain on deglutition. The day following there was a little swelling over the lower part of the larynx externally; this swelling had now nearly disappeared. Pain on pressure over the right side of the larynx. In the evening the patient commenced to be hoarse and the pain on pressure became very violent. Dysphagia, then complete aphonia; no cough. The two arytenoids were red and tumefied, the right rather less than the left; appearance of tuberculous laryngitis. The right cord was immobile during phonation. The remainder of the laryngeal mucous membrane was hyperæmic; the left cord a little injected, the right swollen and red. The treatment consisted in the internal administration of salicylate of sodium. From Feb. 23rd to the 28th there was no amelioration in the throat symptoms, the swelling had increased, and the respiration remained embarrassed. Starting from the 28th and after the application of a blister over the right side of the larynx, and after the administration of iodide of potassium, a notable amelioration took place. Improvement continued, and on March 6th the œdema had completely disappeared. The voice had returned fairly well, but the right crico-arytenoid articulation and the vocal cord remained red and only executed feeble movements."

Of these two patients the first case (that reported by Libermann) was certainly a rheumatic subject, and the second (Mr. Simpson's case) presented other articular lesions. The arthritic diathesis of the one, and the multiple attacks in the two cases, do not allow us to affirm that we had to deal with infectious, and not with true and rheumatic, pains coinciding with the gonorrhœa. At the most, the failure of the salicylate treatment in the second patient would suggest that we had before us a real gonorrhœal arthritis.

In connexion with impairment of movement of vocal cords comes the question of rheumatism of the laryngeal muscles. I am not myself a believer in the rheumatic origin of muscular affections generally. I am of opinion that they are more often due to a gouty tendency. I cannot, therefore, give in my adhesion to the view that the muscles of the larynx may be affected with rheumatism and give rise to impaired movement of the vocal cord, and I agree with Dr. Semon when he says that "I believe the less in rheumatic paralysis the greater my experience becomes." Larauza,[20] however, records a case of hyperæmia of the laryngeal mucous membrane with loss of tension in the vocal cords with aphonia in a patient, the son of arthritic parents, but who had not suffered himself from articular rheumatism. On the very insufficient ground of a rheumatic family history and the speedy improvement under the administration of sodium salicylate after other methods had failed, Larauza diagnosed rheumatism of the intrinsic muscles of the larynx. I have not seen any cases which could not be explained on other than a rheumatic theory.

GOUT.

I have but little to say in reference to gouty conditions of the nose. Tophi are sometimes found in the skin of the nose. At the time of writing this I have a patient in the Westminster Hospital with a large tophus in the skin of the

nose. Sir Dyce Duckworth[21] states that "Painful follicular inflammations in the alæ of the nose have been noted with some frequency in the gouty. These do not suppurate, but are apt to recur again and again." If epistaxis occurs it is usually as a result of changes associated with chronic interstitial nephritis (the gouty kidney) rather than directly due to any gouty condition. In a letter to me on the subject Sir Dyce Duckworth confirms an opinion which I have long held, that "some nasal catarrhs are gouty, sudden, and sometimes fugitive." There is much to be said in favour of the view that in some cases of hay fever there is an underlying gouty tendency or, as Haig would say, a condition of uricacidæmia. I have not, however, found hay fever alternating with, or replacing an attack of, gout. Sir Dyce Duckworth quotes Noël Gueneau de Mussy as being of opinion that cases of hay fever were especially frequent in members of gouty families and, as regarding the changes in the mucous membrane of the nasal passages, as akin to the eruptions which vex the skin of gouty subjects. I have found that a simple unstimulating diet, only a moderate amount of animal food, and no alcohol, suit the victims of hay fever the best. Whilst on the subject of hay fever and paroxysmal sneezing in the gouty, I will take the opportunity of emphasising the importance of a thorough investigation of the patient's general condition before any local treatment is carried out in the nose for these affections. A careful inquiry should be made as to the state of the various functions of the body, especial attention being directed to the condition of the liver and kidneys; the possibility of malarial infection should also be considered. Having done this I would go a step further and if, in spite of general treatment, the sneezing or attacks of hay fever persist I would most certainly carry out local treatment in the nose. Of the methods of local treatment I have found none so efficacious as the use of the galvano-cautery. Given a puffy, spongy condition of the mucous membrane of the turbinated bones, with more or less occlusion of the passages, the application of the galvano-cautery has in my experience been followed by great benefit; it involves little or no risk of any sort and, thanks to cocaine, can be carried out in a perfectly painless manner. Only in exceptional cases is a more severe local treatment necessary, but should there be deflection of the septum partially blocking one nostril it may be necessary to forcibly straighten it and thus restore free nasal respiration. Removal of the turbinated bones is hardly ever justifiable. I have entered somewhat fully into this question of local surgical treatment of nasal neuroses as Dr. Goodhart[22] has, in my opinion, taken up too strong a position when he says "we should remember, in making use of severe measures of this kind, that we are only treating a symptom and, from the nature of the case, adopting a means that is very unlikely to prove of any permanent good." While agreeing with him that "means of this kind are too often meddlesome and bad surgery," I have had so many patients under my care who have derived permanent benefit from the galvano-caustic plan of treatment that I feel it my duty to protest against indiscriminate blame being attached to it, as well as against its unjustifiable abuse. In this, as in most worldly matters, *In medio tutissimus ibis* is the motto to follow.

Though gouty affections of the nose are comparatively rare, the pharynx is frequently the seat of trouble in the gouty—chiefly of a chronic nature, anything like acute gout of the throat being excessively rare. Morell Mackenzie[23] mentions the case of a patient who was "suffering from acute pharyngitis, when the symptoms suddenly disappeared and an acute attack of gout developed in the great toe of the right foot; after three days the gouty inflammation of the toe disappeared and acute hyperæmia of the pharynx supervened." He also mentions a case of acute œdema of the uvula disappearing upon sudden development of gouty inflammation of the big toe.[24] M. Vaton[25] was called to a patient suffering from an urgent attack of dyspnœa with enormous œdematous swelling of the uvula, soft palate and fauces. The patient was the subject of gravel with articular deformities and tophi, and had had gouty attacks previously. The diagnosis of gouty angina was accordingly made and the patient was ordered gargles of chlorate of potassium, sinapisms, and a free supply of Vichy water. As suffocation threatened the uvula was scarified and leeches were applied to it. The swelling suddenly disappeared some days after, simultaneously with the big toe being attacked with severe gout. I have not myself seen anything similar to the above—i.e., acute mischief in the throat being replaced by acute gout, and this in its turn giving way to a return of the throat mischief, on the other hand I have had a good number of gouty patients who have had marked throat symptoms, which seemed to me to be dependent on their general gouty condition. The appearance of the gouty throat is characteristic, the soft palate, the fauces and the posterior wall of the pharynx present a gorged, congested appearance, the uvula is generally enlarged, and sometimes of an enormous size. The colour of the mucous membrane is purplish-red and has a somewhat glistening appearance. As regards symptoms, patients complain of all degrees of discomfort, from slight difficulty and pain in swallowing to sharp pain radiating up to the ear, with excessive pain on swallowing. In some cases the patients complain of pain limited to certain areas, or they have the sensation of tickling or of a foreign body in the throat. These symptoms are especially met with in the lithæmic; i.e., in people with defective liver action but who have not as yet shown any overt manifestations of gout.

I am of opinion that quinsy is sometimes a manifestation of the gouty diathesis and occurs in the children of gouty parents more frequently than in others. In the past the diagnosis of gout has undoubtedly been the refuge of the destitute, and I do not think that we are justified in describing an affection of the throat as being gouty, unless the sufferer has had some other distinct evidence of gout. The gouty nature of the complaint is still further assured if it quickly yields to colchicum and alkalies when other remedies have failed. In connexion with gouty pharyngitis it is not uncommon to find the larynx also affected. The cords are congested and the mucous membrane of the larynx has sometimes a dusky colouration. The patient complains of pain through the larynx, and there may be some external tenderness. There is usually hoarseness, with a frequent hacking cough, and a little viscid expectoration, sometimes streaked with blood, is brought up with difficulty. Sir Thomas Watson, in his classical lectures, writes: "A year or two ago an eminent physician of my acquaintance suffered a violent and dangerous attack of what was considered to be gout in the throat." It is extremely difficult to recognise what was included under the term of "gout in the throat" in the pre-laryngoscopic days, but it is quite certain that nowadays we do not see gout attacking the larynx and threatening life. The only two cases of a definite gouty affection of the larynx which Morell Mackenzie[26] records are (1) gouty deposit around the crico-arytenoid joints on both sides, causing permanent dysphonia, deposit in lobule of left ear; (2) gouty inflammation, producing fungous ulceration of the left ventricular band resembling cancer, cured by a course at Wiesbaden. Sir Alfred Garrod[27] writes: "In one instance only have I seen what appeared to me to be a true gouty disease of the larynx." Inasmuch, however, as no laryngoscopic or post-mortem examination was made the case is not conclusive. In my experience gout as it affects the larynx has been in the form of catarrh, more or less chronic, but yielding to alkalies and iodide of potassium. Careful pathological investigation bears out the comparative rarity of gouty changes in the larynx. Dr. Norman Moore[28] has noted the post-mortem appearances in eighty cases of gout and, as one of his conclusions, states that "the articulations of the larynx rarely contain deposit"—i.e., of urate of sodium. On analysing these eighty cases it will be found that in fifty-seven cases the larynx was normal (except one case where there was tuberculous ulceration), in sixteen cases the condition of the larynx is not distinctly indicated, and in only seven were there any noteworthy changes. In four calcification of the cartilages is mentioned as being present, and in three others gritty deposits, small thickening of white colour, and œdema of the larynx, respectively, were noted. In no case was urate of sodium noted as being present. In the report of a case in the Pathological Society's Transactions Dr. Moore,[29] however, mentions the occurrence of a small deposit looking like urate of soda just below the outer end of each cord. In one case Sir Alfred Garrod[30] met with some points of deposit on the arytenoid cartilages, which

were proved to consist of urate of soda both from their microscopical and chemical characters, and Duckworth[31] states that Virchow has detected "a tophulus" in the posterior part of the right vocal cord. Uratic deposits have been found in the crico-arytenoid ligaments. Ewart[32] quotes cases observed by Litten and Brooks of uratic deposits in the larynx.

OSTEO-ARTHRITIS: RHEUMATOID ARTHRITIS.

Osteo-arthritis affecting the crico-arytenoid joint has up to the present time received but scant attention. Sir Alfred Garrod[33] is inclined to attribute the aphonia, which he has observed in several cases, to implication of the arytenoid cartilages in the disease, but this view has not been confirmed by laryngoscopic or post-mortem observations. Bearing in mind how generalised the joint lesions of this disease are, I cannot but think that cases in which the crico-arytenoid joint is implicated occur fairly frequently but pass unrecognised, for I can see no reason why this joint should be exempt from the ravages of osteo-arthritis, more especially as a neighbouring joint—the temporo-maxillary articulation—is often attacked. Now that the laryngoscope is so commonly employed we may expect to hear of osteo-arthritic affections of the crico-arytenoid joint.

Dr. W. E. Casselberry[34] of Chicago has recorded the case of a woman, fifty-eight years of age, who suffered from laryngeal dyspnœa, marked inspiratory stridor, and a slight degree of laryngitis. The vocal cords could not be abducted on account of ankylosis of the arytenoid joints; the patient suffered from general rheumatoid arthritis of the joints of the hand and foot as well as of the larger joints of the body. The attacks of laryngeal dyspnœa always terminated spontaneously, and they corresponded in point of time to the exacerbations of the constitutional affection. During the attack itself local treatment was necessary in order to keep the larynx free from secretion; without this it would hardly have been possible to avoid tracheotomy. Treatment directed against rheumatism and against gout was carried out for a long time without result. It would seem, therefore, that in this case we had to do with osteo-arthritis of the crico-arytenoid joint.

LEUKÆMIA.

Several cases of laryngeal stenosis due to leukæmia have been reported.[35] In a case under Ebstein's care the arytenoids and ventricular bands were infiltrated. Three months after the first observation the swelling had increased and had extended to the supra-glottic region, the surface being covered with a yellowish secretion. Owing to an increase in the amount of stenosis tracheotomy was required. Death occurred five days later. In another case the laryngoscopic appearance was that of a tuberculous infiltration, and the stenosis was chiefly due to swelling of the sub-cordal mucous membrane extending posteriorly to the sixth tracheal ring. Mager records the case of a patient, fifty-eight years of age, who, after having suffered from leukæmia for a year, became dyspnœic. On laryngoscopic examination the mucous membrane of the larynx was red and swollen; the swelling appeared to be due to a hard infiltration, the vocal cords were swollen, and there was immobility of the right half of the larynx. Death followed tracheotomy in a few days. In this case at the post-mortem examination, in addition to the usual sub-epithelial infiltration by leucocytes, there was perichondritis and necrosis of the right arytenoid cartilage. Leukæmic infiltration of the larynx represents a grave complication; it usually requires tracheotomy and is a precursor of the fatal issue.

HODGKIN'S DISEASE.

In Hodgkin's disease running an acute course œdema of the pharynx, especially of the arches of the palate and the uvula, coming on in successive attacks has been observed.[36] The swelling is probably due to leukæmic infiltration and the administration of arsenic has good effect. In a chronic case of Hodgkin's disease an œdematous granular appearance of the uvula and the anterior palatine arch, which felt hard, was noticed. A similar condition has been seen in the larynx. A child, two years old, had attacks of suffocation and died, notwithstanding the performance of tracheotomy. At the post-mortem examination there existed a general swelling of the lymphatic system, with especial localisation in the ventricular bands and the epiglottis. The swelling of the laryngeal mucous membrane was pale and slightly knobby, caused by accumulation of leucocytes in the sub-epithelial tissues.[37]

LYMPHATIC SYSTEM.

Owing to the universality of its distribution the lymphatic system necessarily plays an important part in all diseased processes. As Moritz Schmidt has pointed out, in a considerable number of cases of recurrent posticus paralysis the cause is quite obscure during life. A likely hypothesis in these cases is that the paralysis has been produced by a swollen mediastinal or cervical gland. I have had the opportunity of watching such a case for the last ten years and though I had always assumed, in the absence of any other recognisable condition, that the paralysis was due to the pressure of enlarged mediastinal glands, it is only within the last few months that the cervical glands have become enlarged and lent support to my original diagnosis.

HÆMOPTYSIS.

There is hardly any symptom which gives rise to more anxiety both to the patient and his medical attendant than hæmoptysis. The rule still holds good that blood which is coughed up should be regarded as coming from the lungs, until there is distinct evidence to the contrary. A simple explanation of some cases of blood-spitting occurring in the early morning is forthcoming—viz., that it may be due to decayed teeth. Patients suck their gums and if the gums are inflamed the blood drawn from them during sleep passes into the throat to be coughed up on waking. Numerous cases are now on record in which a varicose ulcer on the posterior border of the septum, small ulcers and vascular ruptures in hypertrophied tonsils, enlarged vessels in the pharynx, a varicose condition of the veins at the base of the tongue, dilated vessels, or ulceration of the larynx, have given rise to the suspicion of hæmoptysis, and the diagnosis has only been arrived at by the employment of the rhinoscope or the laryngoscope as the case may be. I could not wish to cite a better illustration of the use of these instruments in general medicine. Among the comparatively rare causes of hæmoptysis may be mentioned the presence of a leech in the larynx.[38] A dry laryngitis, in which crusts form on the vocal cords, may give rise to quite a severe hæmorrhage when they become detached, and this, together with the concomitant cough and hoarseness, may, in the absence of a thorough examination, lead to an erroneous diagnosis of phthisis. I have had under observation during the past year a middle-aged lady with the physical signs of a small quiescent cavity in the apex of the right lung, who came to me with the history of having spat blood daily for over a year. There was no rise of temperature and the patient had gained in weight. Examination of the sputa on two occasions showed the absence of tubercle bacilli. I thought that I had discovered the source of the hæmoptysis when I detected bleeding from a vascular point on the septum. The epistaxis I readily stopped by applying the galvano-cautery to the bleeding point, but, alas, the hæmoptysis continued and, though I carefully examined the pharynx and larynx, I failed to find the origin of the hæmorrhage. I am confident, however, that it came from the upper air passages and not from the lungs.

BRONCHITIS.

The intimate connexion between the nasal passages and the bronchial tubes has for a long time been common property. There are certain persons who say that whenever they get a cold in the head it is sure to travel downwards and set up bronchitis. This tendency is, however, much greater in those who suffer from stenosis of the nasal passages interfering with proper nasal respiration. This is one argument I employ when I think it necessary to advise that hypertrophic rhinitis, crests on the septum, and deflected septa should be surgically treated. I point out that, though in early adult life the nasal condition may only be an inconvenience, still with advancing years and the tendency to bronchial affections which comes with increasing age, any interference with free nasal breathing greatly aggravates the risk of being attacked by bronchitis. Oral respiration is always attended sooner or later by chronic pharyngitis and laryngitis, and a little additional upset of the system will start bronchitis, which under these circumstances is

extremely likely to become chronic. Even slight nasal affections, not sufficient to interfere with breathing, may be a predisposing cause to bronchitis. Thus Cahn[39] records a case of bronchitis coming on in an acute manner in a patient with small nasal polypi, and the bronchitis lasted until they were cleared out. Cahn especially notes that there was free nasal breathing.

ASTHMA.

One of the earliest reflex conditions which was recognised as being dependent in some cases upon intra-nasal disease is asthma, and though I cannot agree with some authorities that asthma is usually associated with intra-nasal diseases, still cases of this sort occur with sufficient frequency to render it absolutely necessary for the physician to examine the nose in all cases of asthma. Numerous cases have now been recorded of asthma occurring in persons suffering from nasal polypi, in which the removal of these growths has completely freed the patient from an attacks of asthma. It has not, however, been my fortune to meet with absolute success—that is to say that in all the cases of asthma complicated with polypi which have come under my care in no single instance have I succeeded in curing the patient by removing the polypi. No matter how thoroughly the nose has been freed from the growths, the patient has still suffered from attacks of asthma, though the effect of the treatment has been greatly to diminish the attacks in frequency and severity. Unfortunately, as a rule, patients do not come for treatment of the nasal disease until the asthma has lasted for a considerable period, possibly years, and by this time changes have been set up in the central nervous system and in the lungs which are incompatible with complete restoration to health. In this connexion the following case is of much interest.

A man, aged thirty-eight years, consulted me in April, 1893, on account of asthma from which he had suffered for about six or seven years. At the commencement of the asthma he had some sneezing. On examining the nose I found a spur on the septum, no polypi and nothing abnormal in the naso-pharynx. The chest was emphysematous. I ordered him iodide of potassium three times a day and the following mixture to be taken for relief of cough and shortness of breath: one-third of a minim of liquor trinitrini, half a drachm each of oxymel scillæ and tinctura camphoræ composita, twenty minims of spiritus ætheris nitrosi, and water to half an ounce. He came again in two months' time and reported that he had had great relief from the treatment. He now mentioned that he had a clear, watery discharge from the nose at the time of the attack. I applied the galvano-cautery to the right inferior turbinal I lost sight of the patient until April, 1896, when he again came to see me and said that he had been very well until the last few weeks. On examining the nose I found polypi in both nostrils. I cleared out the nostrils much to his relief in all respects. The particular interest of this case is the connexion of the asthma with nasal trouble. At the commencement of the asthma he had sneezing; the onset of an attack was accompanied by a watery discharge, but it was not until the asthma had existed for at least seven years that polypi developed in the nose. I have seen many cases of asthma complicated with nasal polypi, but this is the only example I have met with in which polypi appeared in a patient already suffering from asthma.

Though polypi represent the intra-nasal lesion most frequently found associated with asthma, any affection of the nose may be the starting point of asthma. Spurs and crests on the septum, deflection of the septum, hypertrophic and atrophic rhinitis have been noted as apparently giving rise to asthma. Adenoids may also cause asthma. A patient of mine, aged twenty-one years, who had suffered from asthma for two years completely lost it after the removal of adenoids. According to Lichtwitz[40] symptoms resembling asthma were seen in five patients as a complication of empyema of the accesory nasal cavities. Believing as I do in the connexion between intra-nasal lesion and the development of asthma, I would strenuously advise that a systematic examination should be made of the nasal fossæ and accessory sinuses, and if any gross lesion is found it should be promptly treated.

EMPHYSEMA.

Emphysema is another lung affection which has intimate relation with diseases of the nose and throat. Any of the various causes of nasal obstruction may, as a result of the chronic pharyngeal and laryngeal catarrh and consequent irritable cough thereby produced, give rise to emphysema. It is probable also that emphysema may be directly due to nasal obstruction; this is borne out by the experiments of Dr. Cervello[41] on dogs. He finds that occlusion of the nostrils invariably produces in a few days pulmonary emphysema in completely healthy dogs. I have seen the progress of a somewhat rapidly increasing emphysema at once checked by the amputation of an elongated uvula, and I have seen equally good results from the treatment of granular pharyngitis by the galvano-cautery. These remarks will, I think, be sufficient to indicate the desirability of looking out for the cause of any chronic cough, and not to be satisfied with simply ordering some cough mixture. Amputation of the uvula is an operation which has been much abused in the past, but there is no reason why on this account it should not be performed in suitable cases. If the uvula is elongated in a patient who is suffering from a chronic cough, with little or no expectoration, and nothing in the chest can be found to account for it, and if the cough is worse at night or on lying down, then the uvula may with advantage be amputated.

PNEUMONIA.

Epistaxis is sometimes observed in pneumonia; it may be an early symptom or occur as one of the critical phenomena. Just as acute rheumatism may follow an attack of tonsillitis, so I believe may pneumonia. Whether the pneumonia is of septic origin or whether the micro-organism (be it the diplococcus of Fraenkel or the pneumococcus of Friedlaender) first sets up inflammatory mischief in the tonsil and then proceeds to affect the lung I must leave to be settled by those skilled in bacteriology. Dr. Wallace of Crick[42] has recorded a case of the kind. The patient, a man thirty-six years of age, had an attack of sore-throat (quinsy) followed by pneumonia. Examination of the sputum showed numerous long chains of streptococci, staphylococci, pneumococci single, double, and in short chains, and zoogleæ of micrococci. In a patient in the Westminster Hospital under my care an attack of acute laryngitis came on during the course of a pneumonia.

SHAPE OF THE CHEST.

The state of the nose and naso-pharynx has a profound influence on the shape of the chest. Any interference with free nasal respiration, whether in the nose or naso-pharynx, in early life will give rise to a characteristic deformity. Adenoid vegetations, as being the most common cause of defective nasal breathing, are usually found to be present. At one time it was thought that enlarged tonsils were the cause of this deformity, but the observations on which this view depended were mostly made in the pre-adenoid days, and as adenoids are almost invariably associated with enlarged tonsils, it is probable that the latter usually play quite a subordinate *rôle* in the production of the deformity in question. That enlarged tonsils alone are capable of causing deformity of the chest is shown by two cases reported by Dr. Norman Moore.[43] He made a cystometrical drawing of the chest in each case before and some time after the removal of the tonsils, and the cup-shaped depression in the chest which was present before the operation was found to have disappeared when the second tracing was made. My colleague, Mr. Tubby,[44] has given an excellent representation of the changes seen in the thorax. "The chest is bulged at its upper and middle part and retracted in its lower part and excavated. The sternum is not so keel-like as in rickets and the lateral vertical grooves are absent. The antero-posterior diameter is increased, while the transverse is diminished." The retraction of the lower part of the chest is due to the contractions of the diaphragm drawing in the chest, which is insufficiently inflated with air owing to the interference with free nasal respiration. If the adenoids or other causes of nasal obstruction are removed before the bones are firmly ossified the deformity may be almost completely cured, and recovery of the shape of the chest is accelerated by the judicious employment of extension and gymnastic exercises. According to Mr. Tubby,[45] during infancy and early childhood the subject of nasal obstruction shows deformity of the chest alone; between the ages of six and ten years kyphosis makes its appearance; and from

ten to sixteen years of age scoliosis supervenes on the kyphosis.

DISEASES OF THE CIRCULATORY SYSTEM.

As we have already seen in connexion with rheumatism the heart may become affected with valvular disease as the result of a rheumatic tonsillitis, but it is not so generally recognised that an infective endocarditis may have a tonsillar origin. A case reported by Charrin[46] is a good illustration of this connexion. On post-mortem examination staphylococcus aureus, which during life had been found swarming on the exudation over the tonsils, was present in the bronchopneumonic patches and the valvular vegetations. Dr. Dreschfeld,[47] in describing the paths of entrance of the microbes in infective endocarditis, says: "Probably the tonsils, which are so often affected in rheumatic endocarditis, may occasionally serve as the means of entrance, and thus again some of the so-called 'primary cases' may be explained." Löri[48] states that in four out of five cases of acute septic endocarditis, which he has observed, ecchymoses have been present in the pharynx, larynx, or trachea. Loss of substance in the larynx and hæmorrhage from the pharynx, larynx, and trachea have been also met with in acute septic endocarditis. Von Stein[49] of Moscow, as the result of an examination of the symptoms observed in fifty patients suffering from cardiac neuroses, and presenting at the same time an increase more or less pronounced in the size of the inferior turbinals, has ventured to draw the following conclusions. 1. A hyperplasia, more or less marked, occupying in the greater number of the cases exclusively the two inferior turbinals, without points of irritation or hyperæmia, but with complete or intermittent obstruction of the nose, causes a sensation of weight, of constriction, and of angina in the cardiac region. 2. When to this condition is added a transitory vascular injection of the ocular conjunctiva and of the extremity of the nose, an injection which is reproduced by lightly touching the nasal mucous membrane, then there will be palpitation of the heart, often accompanied by sensation of giddiness, of want of air, and of pre-cordial weight. Von Stein has found these symptoms disappear after cauterisation of the mucous membrane.

Tachycardia may be associated with intra-nasal disease. Mr. Spencer Watson[50] has reported a case of nasal polyi in which the pulse-rate was 120 per minute, the tachycardia being persistent. After the nostrils had been completely freed from obstruction the cardiac trouble ceased. In contra-distinction to tachycardia, a slow pulse may be met with in certain nasal affections. Lichtwitz[51] reports the case of a patient with empyema of all the sinuses, who had a pulse of from 28 to 30 to the minute, which became normal after treatment. Tachycardia has been observed to follow excision of the larynx.[52] It has been suggested that is was due to division, in the course of the operation, of an abnormal cardiac branch of the superior laryngeal nerve, with functions similar to those of Cyon's depressor nerve. Dr. Toti, however, relates a case in which the patient developed intense tachycardia (from 160 to 180 beats a minute) *thirty hours* after the operation for total excision of the larynx. He continued in that state for twenty-four hours, and ultimately died from cardiac paralysis. If, however, the tachycardia were in this case the result of the division of the nerve, it ought to have appeared immediately after the operation, instead of being delayed for thirty hours. At present, therefore, no satisfactory explanation of the occurrence of tachycardia in these cases is forthcoming. Besides causing tachycardia, nasal lesions occasionally give rise to irregularity in the action of the heart. Dr. Sansom[53] in a discussion following the reading of his paper entitled "The Irregular Heart: a Clinical Study," read before this society on Dec. 12th, 1892, said: "He thought that nasal and aural troubles were amongst the commonest reflexes which started the cardiac derangement."

EXOPHTHALMIC GOITRE.

In exophthalmic goitre, and, as we have just seen, in the allied condition, tachycardia, intra-nasal changes play an important part. Mr. Arthur Maude,[54] who recently presented his valuable series of monographs on exophthalmic goitre to the library of the Royal College of Surgeons of England, has collected the following cases in which operative interference in the nose has been carried out in cases of Graves's disease. "Hack of Freiburg removed part of the inferior turbinated bones, which were the seat of chronic thickening, in a girl, aged sixteen years, in whom exophthalmos had existed since childhood and palpitation and goitre for many months. The operation was performed with the galvano-cautery, and subsidence of the symptoms followed.[55] Fraenkel[56] also reports the amelioration of symptoms which followed the application of the galvano-cautery to the inferior turbinated bones. The application was made to the two sides at some weeks' interval, and the immediate effect on the goitre was limited to the side treated; after application was made to both sides the thyroid enlargement disappeared and the pulse regained its normal rate. Bobone[57] makes a similar observation. Hopmann,[58] by treating chronic atrophy of the mucous membrane of the nose in a woman the subject of exophthalmic goitre, claims to have cured the palpitation and exophthalmos." A case recorded by Mr. Spencer Watson[59] of a woman, fifty-four years of age, with prominent eyeballs, great mental depression and fainting fits, was probably one of exophthalmic goitre. There was extensive hypertrophy of both inferior turbinals, which were removed with great relief to the symptoms. Dr. Scanes Spicer[60] has recorded a case of incomplete Graves's disease associated with nasal polypi. In this case, although the enlargement of the thyroid gland, the tachycardia, the tremor and nervous excitement were well marked, Dr. Spicer elected to call it incomplete Graves's disease from the subordinate character of one of its leading symptoms—the exophthalmos; the polypi were removed with the cold wire snare, and as the nasal passages gradually became pervious the thyroidal swelling diminished and became less defined, the pulsation less, and the slight exophthalmos and tremors disappeared.

Over against the above cases of exophthalmic goitre successfully treated by intra-nasal operative procedures, must be set the remarkable case of unilateral incomplete Graves's disease after removal of nasal polypi recorded by Dr. Felix Semon.[61] The patient was a man, thirty-three years of age, with multiple polypi in both nostrils. After repeated operations with the galvano-caustic loop under cocaine, it was noticed that the patient's right eye had become more prominent than the left, but there was no enlargement of the thyroid gland, the heart action was quiet, and the pulse-rate normal; in fact, no sign of a lesion of the sympathetic except the unilateral exophthalmos. When the patient was shown at the Laryngological Society,[62] four and a half years later, the pulse-rate had increased to about 100, but the exophthalmos had somewhat decreased; on the other hand, complete baldness, extending over both sides of the head, had developed shortly after the first onset of the symptoms. The hair had also come off from other parts of the body. In connexion with this case it may be mentioned that Mr. R. S. Charsley[63] has observed marked enlargement of the glands in the neck and protrusion of the eyeballs lasting for a period of three months after operation for removal of the turbinate body with the galvano-cautery. The pulse had ranged as high as 110, but complete recovery ensued. The only nasal trouble that I have myself noticed in Graves's disease was very profuse epistaxis in a woman aged forty years. The patient was much weakened by the repeated losses of blood, so I applied the galvano-cautery to the bleeding point and at once arrested the hæmorrhage, which gave her no further trouble. The course of the disease was not apparently modified by stopping the loss of blood and the patient eventually died from exhaustion consequent on profuse diarrhœa.

GATESHEAD CHILDREN'S HOSPITAL.—The annual meeting of the Gateshead Children's Hospital was held on Feb. 19th in the town-hall, Lord Northbourne occupying the chair. The report stated that everything connected with the actual working of the institution had been of the most satisfactory character; the income, however, was insufficient to meet current expenses and at the end of the year there was a deficiency of £119.

ALBUMINURIA IN PREGNANCY.

BY T. CLIFFORD ALLBUTT, M.D. CANTAB., F.R.C.P. LOND., F.R.S.,

REGIUS PROFESSOR OF PHYSIC, UNIVERSITY OF CAMBRIDGE.

A FEW weeks ago when reading a paper on renal disease by the most eminent writer of the day on this subject I was surprised to find the mechanical causation of renal complications in pregnancy accepted without doubt, or with but slight reservation. For some years past this factor in the untoward event had been slipping away from my mind; I had not, and have not, made any personal investigations on the subject, but insensibly the mechanical conception had lost its hold upon me. I did not ask myself how far I was alone in this change of opinion, because if I were alone I had not endeavoured to base the new views on exact research, and could not on my own part therefore claim for them any substantial value. And I regret to say that I am still without this justification. I have not made any careful research into the causation of puerperal kidney disorder; all I can do is to set the problem as distinctly as possible, so that each may work it out for himself. Perhaps it is presumption on my part to bring the matter forward at all at this stage; but I think, seeing that the mechanical hypothesis is so dominant as I have said, it is well if there be an opposite hypothesis to mention the alternative. Truth arises more readily even from error than from confusion. To state a problem clearly is to be well on the way to its solution.

Now that the renal complications of pregnancy are due merely to mechanical pressure I believe to be an erroneous opinion. The evidence, whether clinical or anatomical, in favour of it has for many years seemed to me to be very weak. Yet this explanation is by no means confined to the writer I have referred to; it is generally held. I turn to the excellent hand-book of Dr. Coats as representing the current pathological teaching, and I read[1]: "Pregnancy leads to a chronic nephritis, in all probability by obstructing the vessels of the kidneys by the pressure of the uterus." He adds that there is extreme hyperæmia of the kidney in these cases, a statement which is not universally, if generally, true. Dr. Hamilton seems to have overlooked the subject altogether. To Cohnheim I shall refer hereafter.

Let us examine this facile explanation of venous obstruction a little more closely. It depends apparently on the supposition that the enlarged uterus presses upon the renal veins and thereby raises the venous blood pressure. If the topography of the parts is considered for a moment it will be seen that this encroachment is not so easy as is supposed; it is not easy, however, to pursue the argument from anatomy on this occasion when the parts cannot be demonstrated. Again, complete thrombosis of the renal veins is not followed by renal symptoms which are averted by collateral circulation. Moreover, swelling of the legs and other such signs of venous obstruction get more and more as pregnancies increase in number, whereas albuminuria and eclampsy are evils of the primipara. But, turning to other tumours in the abdomen, see what comes of them. Like all practitioners of large experience I am only too well versed in cases of the huge encapsulated fibroid tumours of the female pelvis, yet I do not remember a single case in which the tumour produced serious kidney disorder, though disturbance of micturition and even pressure on the ureters, followed by dilatation of these tubes, and even by pyelitis, may occur. But in pregnancy there is little evidence of serious pressure on the ureters; I am not aware that dilatation of these tubes is seen as a complication of pregnancy except in rare cases. Again, there are frequent examples of a rise of venous blood pressure in the kidneys in heart disease; but both clinically and pathologically the course of clinical events is very different, I may say wholly different, from that in the renal disturbance of pregnancy, and the morbid anatomy of the kidneys is by no means common to both cases. In the cardiac kidney little degeneration is found and very little inflammation. The capsule as a rule strips off easily; there is not much evidence of cirrhosis, if any; cyanosis and hyperæmia are the most prominent features, and, indeed, there is so little structural damage that the kidney can in a bad case well recover if the circulation were restored. Now, in the puerperal kidney we find a great contrast to the cardiac kidney. So far from being a mere congestion, there are signs of acute degenerative processes penetrating the organ in all its tissues. It is not hard as is the cardiac kidney, and it is often pale. Scattered throughout it are points, or more than points, of broken-down structure, and the anatomical elements throughout are blurred and deteriorated. Many vessels are plugged. The kidney looks as if it had been subjected rather to some more intimately mischievous, I had almost said corrosive, action than to a mere mechanical interference. It does not seem, therefore, that the puerperal kidney would fall into the class of venous congestions; it is not the kidney of heart disease; it presents rather the character of an irritation too acute to give time for the cirrhotic reaction which we see in kidneys subjected to the more gradual effects of poisons acting over a long time. Cohnheim, perceiving these difficulties, suggested that the renal disturbance in pregnancy is due to a spasm of the renal arteries—a hypotheis which was suggested to him by the anuria of lead colic, followed by free urinary discharge on the cessation of the colic.

Now is there any alternative to the mechanical hypothesis and to that of spasm of the arteries? On the mechanical hypothesis we assume the kidneys to be so injured by the back pressure that suppression of urine takes place and the patient may thus die of uræmia. I have said that even if one is satisfied that considerable pressure on the abdominal veins is likely to take place in pregnancy such an event is most unusual, to say the least of it, in other cases, such as the cardiac, known to depend on venous retardation. In other such states the kidneys can do work enough to keep the patient from auto-intoxication, and there is some collateral circulation. Yet in the puerperal woman uræmia is only too common. It is idle to be content with the plausible generalisation that the puerperal woman is in a heightened nervous state, due to reflex excitement from the uterus, which makes her obnoxious to perturbations which are comparatively harmless, say, to a patient with heart disease. To go a step backward and ask why this heightened nervous state exists—a state which is adduced as the efficient cause of vomiting, chorea, whimsical fancies, and so forth—will the hypothesis of simple uterine reflex prove satisfactory? Is there anything else in the system which is able to produce this morbid excitability and other symptoms less obviously nervous?

I will consider what is seen in the pregnant woman, especially in the primipara. Braun taught that puerperal albuminuria and eclampsy always depended upon Bright's disease—a view now exploded. Tyler Smith and Leishmann explain eclampsy as a nerve reflection arising eccentrically in the uterus, and the albuminuria he refers to the high arterial blood pressure—a consequence wholly unsupported by evidence. One of the first signs of pregnancy is vomiting, of which the superficial explanation is that the awaking uterus irritates certain nerves which by reflex action set up the symptom. One hears, also, of headaches, faints, nervous irritability, and so forth, as symptoms of like causation. Can there be any agent more directly concerned in these phenomena than the "heightened reflex excitability" so easily assigned? It may be noted that many of the infections begin with vomiting, and in them, as in pregnancy, the vomiting may be persistent, so much so as to signify danger, and even the utmost peril. In many of these infections, also, albumin appears in the urine after a longer or shorter time, and may herald the approach of uræmia, with its eclampsy or coma or both. In the pregnant woman Dr. Barnes and other close and experienced observers give the assurance that the arterial blood pressure is increased, a fact better evidenced by the report of the skilled finger than by illusory sphygmographs. Not only so, but in a pamphlet by Dr. Max Dreysel the assertion, first made by Larcher in 1828, that the heart of pregnant women is hypertrophied is submitted to a close scrutiny, a scrutiny both of published evidence since Larcher's time and of his own personal observations. Dreysel decides that in pregnancy the heart is enlarged in both ventricles and in capacity as well as in thickness of the walls; the hypertrophy is of the so-called "excentric" form. The left ventricle is more enlarged than the right. This hypertrophy is said to occur in all well nourished young mothers; it increases during the course of gestation, is at its

[1] A Manual of Pathology, 1889 edition, p. 810.

Hosted by Google

height at childbed, and disappears at once when delivery is completed. This hypertrophy is attributed by some writers to increased resistance in the peripheral circulation; by others to an increase of the mass of the circulating blood; by others, again, to the interpolation of the placental circulation. Dreysel himself attributes the hypertrophy to the plethora of pregnancy—a position which does not carry conviction to my mind, or even, as it would appear from his words, to his own; he seems to give it for lack of a better.

Now, if in scarlet fever we were to see first vomiting, then nervous disturbances, then albuminuria, then enlargement of the heart—what would be the conclusion in the case? Surely that there is some toxin circulating in the body. Why then in pregnancy should we fail to consider the conclusion which is drawn so readily and so correctly in cases where the presence of a poison is better known? Because we are possessed by the prejudice that pregnancy is a normal process, as no doubt it usually is. But what then? Do we not know that our bodies even in health are dying daily, hourly, momentarily. That we are saved from poisoning ourselves only by the unceasing vigilance of our excretory organs. That if this vigilance be relaxed, or the organs over-taxed, but for a day we feel "bilious," or we become "feverish," or in some other way we exhibit signs of intoxication by waste matters defectively excreted, or perhaps arrested at some stage before that of fitness for excretion. Now can it be in pregnancy that there is some circulating poison which sets up vomiting, albuminuria (which we know that other poisons do) and ultimately even eclampsy. Is there any evidence of such a poison? We must remember that even in Bright's disease, wherein we speak glibly of uræmia as if we knew all about it, we know precious little. The poison of uræmia is as yet undetected. All we can say is that it is not this or that; it is not urea, not uric acid, not kreatin, and so forth. Still it is slowly perverting the peripheral circulation, enlarging the heart, and leading on that series of changes which may ere long burst out suddenly as uræmia, as vomiting, headache, eclampsy, or coma. Such a series we can see in lead poisoning; the poison of lead acts the whole play for us; it embarrasses the peripheral circulation raises the arterial blood pressure, prevents excretion by overtaxing and laming the kidneys, and this leads to uræmia in its full manifestation. It would seem that two poisons at least are concerned, the one leading to convulsions, the other to coma. In some not infrequent cases the two acting together produce convulsions followed by coma.

The next question is whether, on consideration of this argument from analogy and on searching accordingly for such a poison in pregnancy, there is any direct evidence of a poison capable of causing peripheral resistance in the bloodvessels, vomiting, often severe, sometimes uncontrollable, albuminuria with damage to the kidney as it passes out or tries to pass out, and ultimately, perhaps, an appalling attack of uræmia? There is some such evidence: in the first place it is known that there is a toxin as yet unseparated in healthy urine. The kidney, like the bowel, is a means of escape for poisons formed in the course of degradation of our working tissues or by parisites. In 1881 Feltz and Ritter began to work at the subject of toxins in the urine, and wrote in that year a thesis entitled "Urémie Expérimentale." Their labours were taken up by Bouchard and others, and although the very poison itself defied detection, yet its presence was demonstrated by them beyond question. Healthy urine filtered and neutralised is poisonous to a rabbit in a mean dose of 40 c.c. per kilogramme of body weight. Thus the whole urine of twenty-four hours would kill 30 kilogrammes of rabbit; or to put it otherwise would kill the man himself in 52 hours supposing man to be as susceptible as rabbit and to have no time advantage in excretion. The symptoms produced by this toxin are myosis, even to the degree of punctiform pupil, accelerated respiration, somnolence, falling of temperature, and coma without convulsion or with light twitchings. At first diuresis is observed, until the attempts of the kidneys to get rid of the poison are overborne. In the rabbit towards the end exophthalmos and dilatation of the vessels of the ear are noted. Now what is this poison be it one or more? As I have said it has not been isolated and it is as yet indicated by negatives; it is not urea, it is not uric acid, it is not kreatinin, it is not potassium chloride which, though poisonous, and contributing to the very poisonous quality of the urine of herbivora, can be removed before the experiments are begun. Dr. Thudichum thinks that it lies in the colouring matters of the urine. On the whole it seems as yet most probable that the toxin, or one of several, is absorbed from the bowel, for it is less in amount in a fasting animal, in hibernation, and in the urine after sleep. As it is strengthened by fatigue, as is found when the urine after eight hours labour is used, "fatigue products" may form some part of it; on a day after great exertion the urine is more toxic. On the other hand moderate exercise seems to clear the body, or at any rate the urine, of the poison.

In the next place we inquire where this poison is formed. Is it formed in the kidney? Some experimenters regard the kidney as a mere filter; others regard it as a gland. There is every probability that both sides are right, the glomeruli being filters; the convoluted tubes being glandular in function. The glomeruli are dialysers; if their epithelium be stripped off it seems that their powers of retention, say of albumin, are weakened; and albumin then appears in the urine. But the albumin is not the toxin: merely to alter the venous pressure will produce albuminuria, as we have seen. But the circulation of certain toxins will do the same as that of diphtheria, scarlet fever, of the tubercle bacillus, or again as the products of ordinary putrefaction. Whether these agents in causing lesions of the elements of the kidney act directly or indirectly through the vaso-motor system or still more indirectly by impressing the heart or nerve centres (probably they injure the renal epithelium and allow the albumin to escape) we cannot tell. However these things may be, there is no doubt at any rate that the kidney, like the bowel, is often the channel of the escape of the toxins; and so long as the renal functions are intact, so long the toxin may escape, and usually does so escape, without doing any harm. But this brings us back to the inquiry where are the toxin or the toxins formed? We cannot penetrate so far as this, but we can go one step backward and show that the liver is at fault. The toxin itself, indeed, may be absorbed direct from the bowel, as such bodies are absorbed daily without harm to us; but the means of our impunity is the liver, which, besides its glycogenic functions and its urea-forming functions, is also charged with the neutralisation of the toxins which find their way into the circulation. The tendency to acute atrophy of the liver in pregnant women is well established. The liver may well be a large organ; in the fœtus it is relatively very large, a fact to which I shall return presently. If then for any reason this protective function of the liver be checked, or a larger quanty of toxin be turned into the blood than the liver can deal with, the excess will fall directly on the kidney, and probably will so injure its finer structures that albumin can leak through. More than this it may inflict serious and permanent damage on the kidney itself, not to mention other parts of the body to which it is injurious. My own working opinion is that all Bright's disease is toxic in origin. Uræmia then is a retention of these toxic bodies in the system, and here one word of warning may be spoken, namely, not to regard the mere aqueous element of the urine as a gauge of the elimination of toxines; free urinary discharge may be consistent with a poor content of matters in solution. In fact, if the patient be showing signs of poisoning, it may well be that the urine, whether aqueously abundant or not when injected into the test animal, may be found not more, but less, toxic than at an earlier date. Indeed, this is found to be the fact: when the urine is taken from a puerperal woman suffering from albuminuria and uræmia, and whose kidneys therefore are presumably overtaxed, this urine is found not more but less toxic to animals. Massieu[2] not only arrived at this result as others had done, but he went on to the logical consequence and showed that the serum of such a patient on the other hand is more toxic, and other authors have corroborated his statement. Tarnier and Chambrelent say that the toxic power of this serum is to ordinary blood serum as 3 to 6 c.c. per kilogramme is to 10 c.c., that is, from 3 to 6 c.c. will prove the equivalent of 10 c c. of normal serum; in other words, the serum of an eclamptic woman is always twice as poisonous as the normal serum, and sometimes is three times as poisonous. We have a familiar illustration of this in the fact that the fœtus is too often the test animal; in cases of puerperal albuminuria with symptoms of uræmia the fœtus is poisoned, it is either killed outright or is more or less seriously injured. Hence one great reason for hastening delivery. The serum of such a fœtus has also been found highly toxic, as we should expect; in two experiments it was as 4 c.c. to 10 c.c., in a

[2] De la Toxine de la Sérum.—Thèse de Bordeaux, 1893.

Hosted by Google

third as 6 c.c. to 10 c.c. As I have said just now it is well that the fœtus has a relatively large liver; its kidneys do little or no work till after birth and it is surrounded by fountains of toxins. The water of the amnion contains no toxins; but probably the placenta has some protective functions. In this direction we may find the mode of Colles' law; the syphilitic fœtus slowly distils its poison through the placenta, and the mother is slowly inured to the poison and gains immunity. If poisons be injected into a fœtus and the umbilical cord be tied no harm comes to the mother, but as soon as this ligature is removed the mother suffers at once. This Gusserow has shown conclusively.

To return to the puerperal woman in whom uræmia is established, do we find in her any effect of toxins in other parts of the body? More than one necropsy has been made from this point of view. Perhaps the most careful one was published in 1892 by W. Lindemann of Moscow[3]; the case is useful in this argument as it was not a case of eclampsy, but of persistent vomiting, a symptom which I would indicate as another evidence of a circulating toxin, and not of mere nervous reflex. Lindemann made a most minute investigation of the whole body, and if his observations are supported by other observers the evidences of auto-intoxication will become very strong. It is impossible to give Lindemann's results in full or even in abstract; but I may say in brief that he found those evidences of acute degenerative changes in the liver and kidney which are characteristic of toxic influence. The spleen was also enlarged as has been found in other cases of the kind; indeed, I believe I may say it is usually enlarged in eclampsy and in other deaths in pregnancy and it is vaguely attributed to a "need of compensation in the circulation." Neuritis was well marked in several tracts. The fœtus showed participation in the effects of poisoning and, if not actually killed outright, was not viable.

Now all these features bring the pregnant state into some comparison with the infections. Those who have had large midwifery experience are aware how often albumin, an early sign of a toxic condition of the system, is found in healthy pregnant women, or rather in women showing no other departure from health. I find its frequency variously estimated by sundry authors—namely, from 2 per cent. to 6 per cent. and even to 10 per cent. In these estimates, or in some of them, primiparas are indiscriminately mingled with multiparas; if I take primiparas alone, the percentage is as high as 5 per cent. to 6 per cent. Blot and Litymann, indeed, believe it would be found, if carefully sought for throughout, in 20 per cent. of all pregnant women and much higher in primiparas (Leishmann). I do not go fully into my authorities for these estimates, which would involve some comparison of their respective trustworthiness; it may be sufficient to say that albuminuria is found in a substantial percentage of pregnant women who show no other sign of ill health. As a rule, this albumin disappears within a day or two of delivery, though in primiparas it is longer delayed and is fraught with more danger to the kidneys so irritated. Casts do not seem to have any relation to the amount of albumin or to have any great prognostic value.

Another necropsy illustrative of my present argument was published by Stembo[4] last year. This was made also in a case of uncontrollable vomiting; and signs of extensive polyneuritis were discovered. Albumosuria is found even more often than albumin in these cases; but I will not enter into this part of the evidence, as the albumose may be absorbed from the amniotic fluid, as the lactose, also found in the urine of pregnant women, is derived from the milk. I will turn rather to another interesting point of the present argument—namely, the deterioration of heart diseases in pregnancy. All writers agree that pregnancy bears hardly on sufferers from heart disease; the harm is not altogether or even largely dependent on the strain of labour—it would rather seem that there is something in the pregnant state prejudicial to weak hearts, that in it the cardiac muscle is deteriorated. If this be so, there is no agent so well calculated to deteriorate it as a circulating toxin. Bar and Renon[5] in a case in which a woman died from mitral failure in pregnancy, examined the blood serum in search of the cause. They found the toxicity of her blood serum and also of the urine considerably increased. The kidneys were acting, therefore, better than the state of the heart would have suggested. Our next question will be, whence come this toxin? Is there a microbe of pregnancy, or is the poison generated by the changes incident to pregnancy? If the latter be the case is this poison generated in all cases; or is it peculiar to cases which have gone wrong in some way? Very careful search has been made for a microbe, and certain investigators believed that they have found the offensive parasite. Bar and Renon whom I have already referred to as workers in this field, found streptococci in one case of peurperal eclampsy, but in two subsequent cases they were unable to find any microbe. In all three cases the toxicity of the blood was very high. Leusden[6] made a minute bacteriological examination in two necropsies of puerperal eclampsia. He decided that there was no evidence of a bacterial origin for the toxins. He concluded that the cause of eclampsy is a toxin formed from the blood in the course of metabolism. There were no signs of placental changes. There was no evidence of embolism or of thrombosis to account for the symptoms, whether by travelling "giant cells" or liver cells, or clots. Any such changes found were obviously accidental. In 1892 Favre induced puerperal convulsions by injecting bacteria into pregnant animals, but this proves no more than that the nervous centres were already in a hypersensitive state, which we know to be the case in all pregnancies, a sensitiveness or heightened excitability due in my opinion to some circulating toxins. Here ends what I have to say on the pathology of the question. I will now briefly turn to the symptoms of pregnancy, or rather to some of them.

We know that toxins tend to expend their malignant power largely upon the nervous system; and in proportion, as the nervous system is developed their effects become the more perilous. This is the case in all the infections. Now, the abnormal excitability of the nervous system in pregnant women has been insisted upon by many obstetricians, by none more strongly than by Dr. Barnes. To the many nervousnesses of pregnancy I need not do more than allude, our own experience will supply the examples. We know, moreover, how liable puerperal women are to such nervous diseases as severe headache, chorea, and neuralgia of a peculiarly obstinate kind relieved at once on delivery. Chorea gravidarum, if it does not cease, is modified for the better on delivery. To the vomiting I need not again refer. Dyspnœa is described by many writers and referred to the reflex neuroses. Tetany again is not very uncommon in pregnancy. Neumann has recently reported two cases, and many moreare on record. To eclampsy I need not again refer. Again, it is more and more recognised that neuritis is no very rare sequence of pregnancy. Mobius has just recorded two more cases[7]; and, finally, insanity is but too well known as a result of child-bearing. If, again, we turn our eyes to other symptoms which may well be due to a toxin in the blood, we remember at once the liability of pregnant women to blood disorders, such as phlebitis and thrombosis of the vessels of the brain and other parts. The terrible susceptibility of pregnant or recently delivered women to septic poisoning is too painfully present to our minds; and it suggests that the blood in these cases is already in a state of unstable equilibrium; a state for which a pre-existing toxin therein might account. Finally, as in lead-poisoning and in Bright's disease, we find the red cells diminished both in number and in hæmoglobin value.

One word on the value, if any, of this toxin point of view to practitioners. I fear that I can say no more than this—that the more we know of the real nature of the morbid states with which we have to deal the better we shall be able to treat them. Of definite and immediate advantages I fear I have none to advance. But we are enabled to see more distinctly the reasonableness of certain measures which we have empirically learned to take in cases of danger. Especially does this theory of a circulating toxin in all pregnancies assure us of the usefulness of the precaution of promoting early delivery in cases which lend themselves to this treatment. Even in dangerous and persistent vomiting, if the mother's life be in danger we must bring about expulsion of the fœtus. In eclampsia this is a still more pressing step. We shall most carefully keep an eye on albuminuria, not regarding it as a mere mechanical accident, but as the signal of a danger essentially implicated in the process of pregnancy itself. Any other signs of a

Hosted by Google

toxic state must be minutely observed with a view to the prevention, if possible, of further mischief. As the toxin may, in part at any rate, be absorbed from the bowel, a patient should be carefully dieted from the time of any suspicious symptoms, such as Chaussier's symptoms of violent pain in the stomach—always a precursor of eclampsia. All substances likely to promote gastro-intestinal catarrh—that mother of poisons—should be forbidden. It may indeed be necessary to reduce the diet to milk, which we find to be the diet which lends itself least to the generation of toxins in the body. At the same time by the administration of such antiseptics as salicylate of bismuth, salol, benzo-naphthol, and occasional mercurials we shall try to keep the bowel as clean as possible. Again, knowing now the important part of the liver in neutralising toxins, whatever their source, we shall jealously watch the condition of this precious organ; and if necessary, by estimating the excretion of urea and so forth, we shall keep ourselves informed of its activity. The presence of albumin again will not be overlooked, but rather we shall be diligent in search for it from early periods of pregnancy, especially in primiparæ; and, not being bound by the mechanical hypothesis, we shall remember that albuminuria is by no means a constant forerunner or concomitant of eclampsia. If we have the opportunity of so doing we may test the toxicity of the urine on rabbits, but this is not of much direct help, as a free excretion of toxin is consistent with the retention of much more in a case in which the poison is very actively formed and to test the toxic co-efficient of the blood serum is not often convenient, even if we make the observation. Lapique, at a subsequent sitting of the Société de Biologie, reported that unfortunately he could not find that any diet controlled the toxo-genetic process, nor, indeed, could he find any law or concomitant variation in its oscillations. Happily, it seems beyond all doubt that in the last resort we can stop its formation at once by inducing premature labour, and in cases either of danger to life, or even of danger to an important organ such as the kidneys, we have this means in our hands. Chambrelent[8] stated that the toxic co-efficient of the urine in normal cases of pregnancy falls on delivery, almost at once, from 0·46 to 0·25.

In conclusion, I may be asked why these toxic accidents are prevalent in primiparas rather than in multiparas. Here is, so far as I know, the one argument of those who take the mechanical view of the causation of puerperal albuminuria and kidney disease. My reply to this difficulty is, I admit, a theoretical one. We know that the formation of the toxins is not peculiar to the primipara. On the contrary, the toxic co-efficient of the urine of the multiparous woman is no less than that of the primipara. Her immunity lies not in the prevention of the poisonous brew but in a protection of the system against its consequences. I believe that immunity is gained against the poison of pregnancy as it is against so many other toxins—as, for example, that of scarlet fever. Whether this lies in the brewing of an antitoxin, or in an education of the cells of the body, or, again, in a reinforcement of the capacities of the liver and kidneys enabling them to deal more summarily with the offending element, I cannot say. That primiparas do suffer in large proportion is well shown by Olshausen,[9] who reported that of 200 consecutive cases of eclampsia extending over five and a half years of his experience 74 per cent. were in primiparas. Of these, again, 25 5 were old primiparas. I repeat that the blood serum and urine are as hypertoxic in the multipara as in the primipara. We must surmise, then, that a protection is established during a first pregnancy of a like kind to that of a first attack of many infectious diseases.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.—The annual court of governors of the City of London Hospital for Diseases of the Chest was held on Feb. 18th, Mr. Julian Hill, the treasurer, presiding. The report showed that during the past year there were 939 in-patients under treatment; there were also 16,166 out-patients, who made 68,231 attendances. It had been found necessary to raise a loan as the expenditure had exceeded the income by £2430.

SOME SMALL-POX STATISTICS.

BY SIDNEY COUPLAND, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL.

(*Concluded from p. 513.*)

The types of small-pox.—There is yet another test that can be applied to the alleged influence of vaccination upon small-pox analogous to that derived from a comparison of death-rates. It is that which concerns the *type* of the disease—a study that is further of value as affording opportunity for noting the remarkable modification in course and character that is often exhibited. But this very modification enhances the difficulty of instituting an exact comparison in this respect between the vaccinated and unvaccinated. Small-pox manifests itself in many ways. The peculiar character of the exanthem, the definite stages of its evolution, and the extent of its distribution afford a ready means of classifying cases according to their severity. In no other infective disease is so precise a division possible. Nevertheless, these various types, based on the character of the rash, do not precisely correspond with degrees of severity or gravity. In a class apart stand the truly hæmorrhagic or "malignant" cases, resembling the malignant forms of other specific fevers, where the intensity of the intoxication is such as to cause profound changes in blood and tissue, leading to speedy death, generally before any characteristic papulation has appeared. Or the typical rash may be in abeyance and, so far as the skin is concerned, the only lesions be a wide-spread erythematous or finely morbilliform rash, associated with abundant petechial hæmorrhages. Such cases ought to be clearly distinguished from the other—not infrequent—variety of "hæmorrhagic small-pox," where the hæmorrhage takes place into vesicles or pustules, and where, too, hæmorrhage may occur from mucous membranes, as in the malignant cases. Yet there is this difference between the two forms—the truly malignant is invariably, the secondarily hæmorrhagic not always, fatal. It is not difficult to discriminate four categories based upon the character of the rash, although obviously there are transition forms, which may be placed in one or other group according to the judgment of the observer. These types are—(1) the confluent; (2) the coherent (or semi-confluent); (3) the discrete; and (4) the mild or "sparse," to which the term "varioloid" is sometimes applied—a term just as applicable to any of the other forms that fail to undergo the typical evolution. These abortive cases in the confluent series are characterised by an arrest of the process at the stage of maturation, the desiccation takes place rapidly, without the secondary septic fever intervening, and the abundant staining left after the separation of the scabs is not followed by any marked "pitting." In the coherent class these "formes frustes" exhibit a similar abrupt arrest in evolution, the pustules not developing to the full, whilst in the discrete and mild types the process may be, and very often is, cut short at the papular stage, maturation entirely failing. Now, in both classes of subjects—vaccinated and unvaccinated alike—I have seen this arrest of the stages of the variolous exanthem occur, but with far less frequency in the latter than in the former. It may almost be said to be the rule in the vaccinated and the exception in the unvaccinated, but the term "modified" is hardly applicable to every case if this phrase be solely restricted to the influence of vaccination. Conversely, the eruption in the majority of the unvaccinated goes through all its stages, but in the vaccinated this "unmodified" course is mainly restricted to adults. I am unable to give statistical expression to this experience, and must therefore ignore it here, treating each of the various classes as if it was in its individual components of uniform severity, whereas, had it been possible to have further analysed them in respect to the occurrence or not of secondary fever, the arrest or not of the rash at various periods of its evolution, and the duration of the acute stage, a most instructive comparison might have been obtained. The clinical records of well organised small-pox hospitals can, however, supply this deficiency.

In considering the question of the proportionate distribution of the types of small-pox it will not be necessary to limit the cases to those upon which the attack rates were calculated, and I will therefore include in the analysis all the cases of small-pox known to me to have occurred in the three districts,

Hosted by Google

excluding only those of which particulars as to age and type were not ascertained. This latter deduction made, there was a total of 3342 cases of small-pox—viz., Dewsbury, 1009, Leicester, 357, and Gloucester, 1976, which may be thus classified:—

TABLE IX.—*Types of Small-pox.*

—	Malignant and confluent.	Coherent and discrete.	Mild.	Total.
Dewsbury	272	466	281	1009
Leicester	96	134	127	357
Gloucester	852	619	505	1976
	1220	1209	913	3342

The greater proportionate severity of the cases in the Gloucester outbreak, already seen in its high mortality, is here again apparent, for in that place the "malignant and confluent" types furnished 43 per cent. of all attacked (there were actually seventy-three cases of *malignant* small-pox), at Dewsbury and at Leicester they supplied in each 27 per cent. On the other hand, at Leicester, where the mortality was exceptionally low, the "mild" cases were in excess of the proportions at either Dewsbury or Gloucester, being 35·6 per cent. of the whole number attacked, as compared with 27·8 and 25·6 per cent. in those towns respectively.

Age in relation to the type of small-pox.—Of the whole number 3342 persons attacked by small-pox 1031 (or about 31 per cent.) were under ten years of age, 1477 (or 42 per cent.) were at ages between ten and thirty years, and 894 (or 27 per cent.) were aged thirty years and upwards, figures which correspond with those previously given in respect to the excessive incidence of the disease upon young children. Even if allowance be made for a possibly greater liability on the part of the very young to suffer severely when attacked, it is yet remarkable how much above the ratio just given was that of the same age-period in the severer types of the disease. For of all the cases of "malignant and confluent" small-pox, 53 per cent. were in children under ten years of age, 27 per cent. in persons of from ten to thirty years, and 20 per cent. in those aged thirty years and upwards, whereas of "mild" small-pox only 12 per cent. are to be found in the youngest series, 57 per cent. in the next, and 31 per cent. in the oldest. These ratios of severity of attack, indeed, approximate more closely with the ratios of the vaccinated in these several age-periods, except that as age advances the proportion of the severer types amongst the vaccinated rises. For at ages under ten years the vaccinated were to the unvaccinated as 4 to 74, at ten to thirty years as 55 to 22, and at thirty years and upwards as 41 to 4. These ratios may be better contrasted when placed side by side in tabular form.

TABLE X. — *Proportionate (Percentage) Distribution of Small-pox Attacks.*

Age.	All classes.	Malignant and confluent.	Coherent and discrete.	Mild.	Vaccinated.	Unvaccinated.
Under 10 years	31	53	22	12	4	74
From 10 to 30 years	42	27	47	57	55	22
30 years and over...	27	20	31	31	41	4
	100	100	100	100	100	100

I propose now to consider the relative distribution of these types of small-pox in each of the three districts and at these several age-periods with more precise reference to their relationship to the vaccination condition of the attacked. For the sake of completeness it is necessary to deal with them from two points of view: first, to ascertain the proportionate distribution of these various types of the disease between the vaccinated and unvaccinated respectively; and second, to ascertain the proportion of the vaccinated and unvaccinated amongst the cases of each of the types of small-pox. In Tables XI. and XII. the actual numbers and the percentage rates are given for every place and age on these points, whilst Diagrams 1 and 2 illustrate the general results obtained by combining the figures derived from the three sources.

Proportionate distribution of types of small-pox between the vaccinated and unvaccinated (Table IX.).—It is impossible not to be struck by the fact that amongst the unvaccinated, at every period of life, there was a close correspondence between the proportions of the malignant and confluent attacks, the variations (on the whole series) not amounting to more than 6 per cent., the mean ratio of this type being 67 per cent.; and this correspondence is carried out also in respect to the other types of the disease amongst the unvaccinated, the mean for the mild cases being about 5 per cent. On the other hand, the vaccinated class shows less uniformity in the distribution, for the malignant and confluent cases range from 6 per cent. in subjects under ten years to 24 per cent. in those of thirty years and over, the mean being 17 per cent. The "mild" cases amongst the vaccinated form 72 per cent. of those of this class under ten, and diminish to 33 per cent. at ages thirty years and over, the mean being 41 per cent. Had these variations been merely accidental, and had vaccination no part in creating them, the distribution of the types would have been very different from what actually obtained. For of all the groups, the proportion of malignant and confluent cases was 36·5 per cent., of coherent and discrete 36·2, of mild 27·3 per cent., which would have yielded, had these proportions been equally maintained in each class, amongst the *vaccinated* (2056 persons) of malignant and confluent cases 751 instead of 354, of coherent and discrete 744 instead of 860, of mild 561 instead of 842; whilst the *unvaccinated* (1286 persons) should have yielded of malignant and confluent cases 469 instead of 866, of coherent and discrete 466 instead of 349, and of mild 351 instead of 71 cases.

The information supplied by Table XI. requires little to supplement it. In the age-period "under ten years" the very small figures of the vaccinated class rather diminish the value of the percentages, but it is at any rate of interest to note that at Leicester only two cases, and these of mild type, fall into this category, and that at Dewsbury and Gloucester together there were only five of malignant and confluent type out of 73 attacked, the percentage of mild cases being 74 and 65 for each of these places respectively. On the other hand, the proportion of mild attacks amongst the unvaccinated class was precisely the same at Dewsbury as at Leicester—namely, 9·3 per cent., and only half this figure at Gloucester, where, out of a total of 677 attacks, no fewer than 501 were of the malignant and confluent types. In the age-period "ten to thirty years" it is interesting to observe that the proportion of malignant and confluent cases amongst the vaccinated was much higher at Gloucester than elsewhere, and lowest at Leicester, which also yielded by far the highest ratio of mild attacks. On the other hand—and this again shows the comparative mildness of its outbreak—the proportion of malignant and confluent cases at Leicester amongst the unvaccinated was far below that which obtained either at Dewsbury or Gloucester. In the age-period "thirty years and upwards" the numbers of the unvaccinated are so few as to render the percentages of small value, nevertheless, there is the same predominance of severe cases in this class at each place. Amongst the vaccinated it will be observed that Gloucester again far exceeds Dewsbury or Leicester in the proportion of severe cases.

Proportionate distribution of the vaccinated and unvaccinated amongst the types of small-pox.—Viewing this question from the other side (Table XII.) it is seen that for the whole series the vaccinated were about 62 per cent. of the attacked, that amongst the malignant and confluent they constituted 29 per cent., amongst the coherent and discrete 71 per cent., and amongst the mild cases 92·2 per cent. The great preponderance of unvaccinated children in these communities (93 per cent. of all attacked under ten years) necessarily results in a large proportion of each type being of this class, yet in spite of the small numbers of the vaccinated at this age very nearly one-half of the "mild" attacks were in this category; although the differences between the three communities are very great, owing to these small numbers of the vaccinated attacks. In the other age-periods the smaller proportions of the unvaccinated do not affect the mean being considerably exceeded for the severe cases, and the ratio similarly lowered for the mild attacks, whilst as regards separate districts, the proportion of the vaccinated amongst the severe types is much higher at Gloucester than elsewhere. Thus, then, apart from

the question of manifest modification of the form of the disease, a primary vaccination does undoubtedly exert an appreciable influence in determining the type from which the patient suffers, an influence most marked in early life, but not entirely in abeyance even in advanced age.

In conclusion, I may perhaps be permitted to add that throughout these several inquiries every endeavour was made to deal with the question without bias, and in collating the information to compile the statistics without any preconceptions of their bearing on the main problem. The figures are small indeed compared with those which have been furnished from all quarters upon the question, but at any rate no pains have been wanting to avoid the fallacies which are liable to vitiate returns of this kind. Perhaps the point of chiefest importance in connexion with them is that they are based on small-pox outbreaks in comparatively "unvaccinated" communities, where there could seldom be any doubt as to the fact of non-vaccination or as to this being due to the subject being of delicate constitution. Moreover, on the other side it must not be forgotten that the class of the "vaccinated" is a heterogeneous one, comprising individuals in whom little or no trace of vaccination remained or where it had obviously been very imperfectly performed. I do not find myself able to offer any reliable data upon the attack-rates of the re-vaccinated, who formed, however, a very small contingent of those attacked by small-pox.

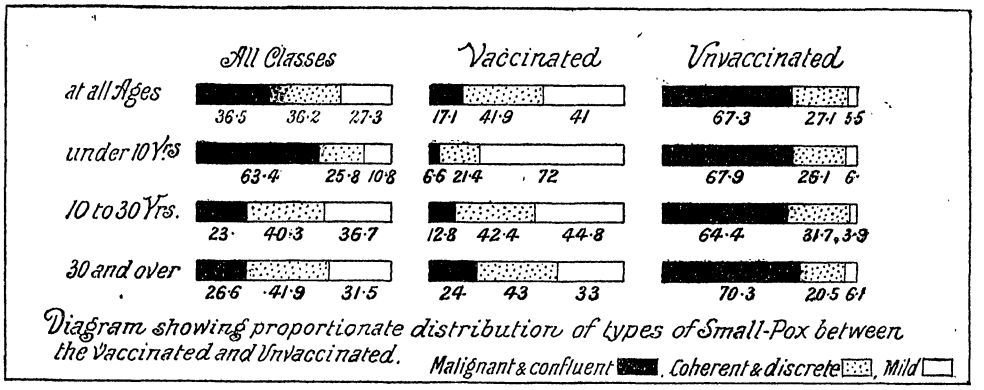

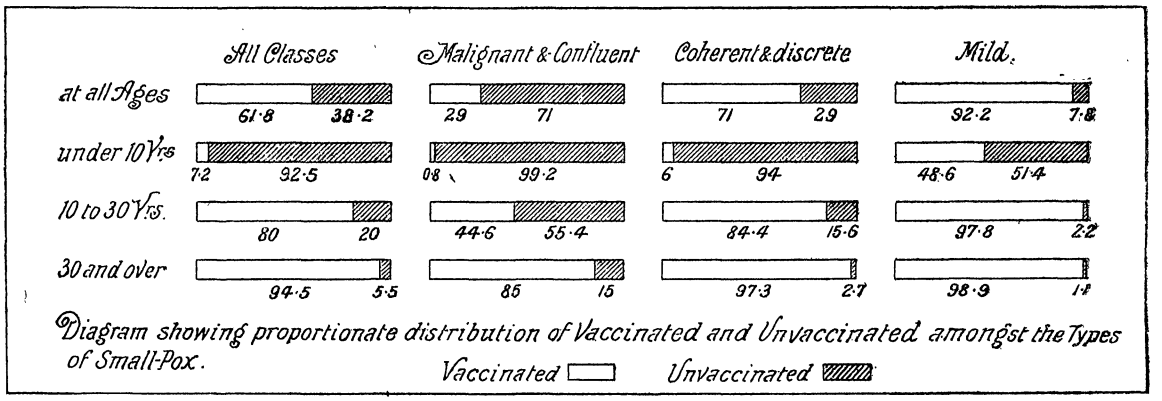

DIAGRAM 2.

Queen Anne-street, W.

CHRONIC INTERSTITIAL NEPHRITIS IN CHILDHOOD.[1]

BY LEONARD G. GUTHRIE, M.A., M.D. OXON., M.R.C.P. LOND.,

PHYSICIAN TO THE REGENT'S PARK HOSPITAL FOR PARALYSIS; PHYSICIAN TO OUT-PATIENTS AT THE PADDINGTON-GREEN CHILDREN'S HOSPITAL AND THE NORTH-WEST LONDON HOSPITAL.

WHEN an adult aged upwards of forty years complains of headache and vomiting, drowsiness, languor and wasting, and on examination we find him sallow, cachectic-looking, and emaciated, the pulse hard, the heart hypertrophied, the urine of low specific gravity and increased in quantity, with or without a trace of albumin, we do not usually hesitate to diagnose granular kidney, although there may never be a sign of dropsy. Then if he dies comatose after a series of convulsions or gets a large cerebral hæmorrhage, the course of the case is not unusual. It is too common to be worth recording. But it is otherwise when young children suffer from similar symptoms. It is true that granular kidney is no longer regarded as essentially a disease of old age, but all agree that it is excessively rare under twenty.

I have collected seven cases of children aged between five and fourteen years who succumbed to chronic interstitial nephritis. In all of these the diagnosis was confirmed by post-mortem examination. Two of these, a girl and boy aged twelve and fourteen years, are recorded by Dr. Dickinson.[2] Dr. Goodhart quotes two from Dr. Ashby of Manchester, both girls, aged ten years and eleven and three-quarter years respectively. He also mentions a boy aged six years who died from the complaint.[3] Dr. W. H. Barlow[4] has related very fully and completely the history of a girl aged five years in whom typically granular kidneys were found after death. Finally I have myself met with a little girl, aged seven years, who suffered from characteristic symptoms of granular kidney during life and in whom the lesions of interstitial nephritis were disclosed by post-mortem examination. A more

extended research into the literature of the subject would doubtless reveal additional numbers, but those collected are sufficient to show the general nature of the symptoms and physical signs which may be expected in the course of the disease. I shall supplement them by impressions drawn from other cases which, being imperfect, I shall not mention in detail.

In this paper the so-called granular kidney is regarded as the product of interstitial nephritis in its last stage. In some of the cases in childhood to which reference is made the kidneys in all respects answered to the classical description of small, red, granular or contracted kidney. In others, as in my own, they were only on their way to become granular or contracted. The process is, I believe, the same in all. It consists in small round cell infiltration of the renal stroma, apparently beginning in the cortex, and spreading in the form of bands towards the centre of the organ. It chiefly involves the glomeruli and blood-vessels at first. In time these bands of cellular infiltration become converted into fibroid tissue which contracts and thus causes peculiar distortion and shapelessness of the kidneys. The capsules gradually become adherent, and sometimes the inflammation spreads beyond into the perinephritic cellular tissue, and may involve the suprarenal capsules, perhaps thus causing definite symptoms resembling those of Addison's disease. The entire process is extremely gradual, and affects successive portions of the kidney until the whole is involved, and the organ becomes generally contracted, or granular. Patches of recent cellular infiltration may be seen side by side with contracting areas of fibrosis. The effects on the secreting structures of the kidney are secondary to infiltration, and subsequent contraction of their stroma. The tubules become narrowed or strangulated and may form small cysts. Their epithelium undergoes fatty or granular degeneration. The Malpighian tufts shrink, and are converted into hyaline or amorphous masses, whilst their capsules are thickened. Parenchymatous changes are always less apparent than interstitial. The walls of the blood-vessels share in the general enlargement which affects those of the arterioles throughout the body. I shall refer to this more fully in dealing with cardio-vascular hypertrophy. Finally, the entire process is extremely insidious and generally slow. The duration of the symptoms affords no clue to that of the disease. There are reasons for believing that interstitial nephritis may commence in early childhood, or even infancy, and not prove fatal for many years. The time at which it causes death will depend on the speed and the degree with which successive portions of the kidney become affected; and also, I believe, on the extent to which cardio-vascular compensation occurs and is maintained.[5]

PHYSICAL SIGNS AND SYMPTOMS.

The most striking physical signs which attend the disease are :—1. Wasting. 2. Dryness, absence of perspiration, coarseness, inelasticity, and pigmentation of the skin, together with anæmia. 3. High arterial tension and cardio-vascular hypertrophy.

The chief symptoms are :—1. Cerebral, including headache, vertigo, vomiting, and convulsions. Tetany and visual disturbances, such as amaurosis or diplopia, have been noted and also cerebral hæmorrhage in two cases.[6] 2. Gastro-intestinal, consisting of easily excited attacks of vomiting and diarrhœa, not necessarily uræmic. Sometimes there may be obstinate constipation or constipation alternating with diarrhœa, epigastric or abdominal pain. 3. Urinary symptoms including polyuria, often associated with thirst, and sometimes with enuresis. Low specific gravity of urine, albuminuria, and hæmaturia. 4. Pulmonary symptoms such as dyspnœa, bronchial catarrh, and those of pulmonary œdema have been noted. Asthma as in adults may possibly occur. 5. Cardiac symptoms, such as præcordial pain or distress with dyspnœa may arise. They do not appear to be so marked as in adults. 6. Dropsy is rarely met with in cases of interstitial nephritis. Yet sometimes slight general anasarca may occur, seldom lasting more than a day or two. It usually is noticed in connexion with an attack of headache or vomiting, and is associated with scanty, smoky, and albuminous urine containing blood casts. Such attacks might be considered to mark the onset of the mischief, but the general appearance and condition of the patient show that the disease is of long standing, although the dropsy and hæmaturia have been the first indication of illness.

Wasting.—The patients are generally stunted, undersized, and wizened. The wasting is usually of long standing and often dates from some illness in infancy or early childhood associated with vomiting, diarrhœa, and great prostration. Wasting, when of long standing, is apt to be regarded as constitutional, or as the patients' normal condition. Advice is not sought because they are thin, but because they easily take cold or bronchitis and suspicions of phthisis have been aroused, or on account of headaches with or without attacks of diarrhœa or vomiting. More rarely we see them because they are always thirsty, pass large quantities of urine and are supposed to be diabetics. (Diabetes, by the way, like "consumptive bowels," is more readily suspected by the public than by medical men.) With polyuria and thirst there may be incontinence of urine, and this is the first symptom which has attracted attention. Wasting is from the first associated with a peculiar dryness and deficient perspiration of the skin, which later on becomes inelastic, and when pinched up, tends to remain in folds and wrinkles. This inelasticity is a most unfavourable sign. Dr. Eustace Smith has drawn attention to the condition which he rightly regards as significant of renal mischief in infants and young children. It is also met with in adults who are suffering from interstitial nephritis. Commonly the gums and conjunctivæ are singularly pale, but there is general capillary congestion which produces a dusky flush in the face and masks the anæmia.

Pigmentation.—With dryness, coarseness, absence of perspiration, and eventually inelasticity of the skin there is often pigmentation or discolouration, varying from mere sallowness to marked bronzing usually general in distribution, sometimes intensified in patches. Pigmentation is a physical sign which, although alluded to in text-books, has not, I think, received the attention it deserves. Bartels says: "In this disease [granular nephritis] the skin not infrequently assumes a dirty faded colour." Dickinson mentions that one of his patients exhibited an appearance which he describes as "pallor luteus." Barlow was struck by the "brownish yellow" discolouration of the skin, contrasting with the steely whiteness of the conjunctivæ which his patient presented. My first patient, who died, looked dirty, though not actually so. Her general appearance was that of an anæmic person who had been much browned by the sun. Here and there the skin assumed a purplish hue due to capillary engorgement. Other cases seen since have led me to regard this pigmented appearance as a great aid in the diagnosis of interstitial nephritis. On several occasions I have been led by this alone to test the urine of children and usually it has been found in such cases to be slightly albuminous and of low specific gravity. Further examination has also brought to light other symptoms and signs of the disease. The pigmentation in many respects strongly resembles that of Addison's disease, but it has not been found to affect the mucous membrane, neither have the "sepia spots" and melanosis of old scars, characteristic of Addison's disease, been observed. It is usually more marked about the abdomen and flanks than elsewhere, but sometimes is seen to excess in the folds of the axillæ and groins. Within the last four years I have met with three girls, aged nine, ten, and eleven years respectively, who all showed marked pigmentation of the body generally. In two of them a diagnosis of Addison's disease had been actually given. But in all three it seems more likely that interstitial nephritis was the primary condition, for two of them had fairly well-marked signs of cardio-vascular hypertrophy and slight albuminuria, whilst the urine of the third is habitually of low specific gravity and its amount is considerably above normal. The duration of the pigmentation—eight, ten, and four years—the absence of perspiration and presence of a dry, coarse skin are also against the diagnosis of Addison's disease in all three cases. Two of these are at present under observation; the history of the third cannot, unfortunately, be traced. Such pigmentation occurs in adults also and may lead to confusion.

I have post-mortem notes on two women, both aged thirty-six years, who died in the North-West London Hospital. They were both under the care of my colleague, Dr. Harry Campbell. My notes state that both showed marked general umber-brown discolouration of the skin, not more

[5] The pathology as given above is not in accordance with the more modern views that granular kidney is the product of parenchymatous atrophy rather than of interstitial inflammation. A discussion as to the correctness of either theory would be out of place in a paper which deals with diagnosis and treatment rather than morbid anatomy.

[6] Filatoff records a third in a child aged eleven years. Emmet Holt, Diseases of Infancy, 1897, p. 621.

Hosted by Google

excessive about the neck, axillæ, and inguinal folds than elsewhere. Both bodies were much emaciated, but not dropsical. The kidneys in both instances showed most advanced granular degeneration. The suprarenal capsules appeared normal in one case, but in the other the right adrenal was firmly adherent to the under surface of the liver. In the latter case the heart showed no signs of hypertrophy, neither were the arteries thickened, but in the former cardio-vascular hypertrophy was very considerable. Dr. Campbell tells me in a letter concerning them: "The first case I was actually inclined to diagnose as Addison's disease on account of the pigmentation, anæmia, prostration, and vomiting (which latter was, as it turned out, uræmic). I did not suspect granular kidney in the second case until the albumin was discovered, for the cardio-vascular changes were not obtrusive. I can recall two other cases of granular kidney recently seen in which the pigmentation was well marked. These patients were well past the middle age, and there could be no mistake about the diagnosis."

I would draw attention to the fact that children often suffer from severe enteritis at the commencement of their troubles. I shall presently mention cases which seem to show that acute interstitial nephritis may occur in infancy with mainly gastro-intestinal symptoms, and shall suggest that this may end in the more chronic varieties of granular kidney.

The cause of pigmentation in interstitial nephritis is sometimes probably interference with the functions of the suprarenal bodies by the morbid processes affecting the adjoining kidneys. It is true that with the exception of Dr. Campbell's case to which I have alluded no mention is made of the suprarenal capsules in the fatal cases which I have collected, and the presumption is that they appeared healthy. But in my own fatal case there was considerable inflammatory matting noticed about the peri-nephritic cellular tissue. It is possible that although the adrenals themselves looked healthy yet their vessels and lymphatics may have been involved in the inflamed tissues around, and thus the organs may have been rendered functionless. Dr. Rolleston [7] suggests a similar explanation of cases of Addison's disease, in which the adrenals have been healthy, whilst the sympathetic or semilunar ganglia have been involved in adhesions or a new growth, such cases having been held to support the sympathetic origin of Addison's disease. Dr. Rolleston's explanation may account for pigmentation in some cases of interstitial nephritis; or it may be that general deterioration of the blood in interstitial nephritis tells on the adrenals as on other organs and interferes with their functions. In cases of long-standing exophthalmic goitre the skin often becomes deeply pigmented as in Addison's disease. In the museum of St. Bartholomew's Hospital there is a coloured picture of a female, labelled "Addison's and Graves's disease." One of the most marked degrees of pigmentation that I have ever seen was in a woman, aged about sixty years, whom I visited in consultation with Dr. Rountree of Camden Town. She was dying from heart failure consequent on Graves's disease of many years' duration. She died shortly afterwards, but unfortunately a post-mortem examination was not allowed. The causation of pigmentation in Graves's disease is as obscure as in interstitial nephritis, pregnancy, and, one may add, in Addison's disease itself. Morbid conditions of the abdominal sympathetic will not alone account for it because they are not constant. Perhaps when we have said that toxæmia is the result of disease affecting the thyroid gland, the suprarenals, and the kidneys, and that such toxæmia in some manner interferes with the disposal of pigment by the "carrier" cells, we have admitted as much as our present knowledge of the subject allows.

The causes of pigmentation cannot be fully discussed here; the point on which stress is laid is that pigmentation practically indistinguishable from that of Addison's disease is a most important diagnostic sign of interstitial nephritis in both old and young, although not existing invariably.

Cardio-vascular conditions.—In all the fatal cases but one marked hypertrophy of the heart was noted; in the remaining one the heart is said to have been found widely dilated after death. Probably the dilatation here was secondary to hypertrophy. In an unfinished case of Dr. Goodhart's it is stated that the heart and vessels were normal, and also in one of Dr. Campbell's cases to which I have alluded. Thickening of the vessels in the kidneys and elsewhere was observed in several of the fatal cases. Though it is not mentioned in all yet it is almost certain that the condition would have been found if looked for. Cardio-vascular hypertrophy is, therefore, in children as in adults, a most useful indication of interstitial nephritis. Increase of pulse-tension during life is not recorded except in my own cases, where it attracted attention from the first. Yet there can be little doubt that when the heart is found hypertrophied and the vessels thick after death there must have been high pulse-tension at one time or another during life. Possibly it escaped observation, as in most of the fatal cases the diagnosis of interstitial nephritis was not completed during life. One's estimation of the hardness of a pulse is apt to depend to some extent on the knowledge that albuminuria is present. If albumin is found the nicety of one's perception appears to be increased, and a pulse is recognised as hard which was previously not accounted so. I do not mean to imply by this that the high tension is imaginary, but that it may be unrecognised unless one is prepared to find it. In young children the pulse-tension may in some cases be difficult to gauge owing to the smallness of the vessel, but, as a rule there is no such difficulty. As regards the physical signs of cardiac hypertrophy, by the time children come under observation, increase in size of the left ventricle is usually obvious; but in earlier stages the hypertrophy is only manifest after repeated examination. It should be remembered that in young children the apex beat is normally nearer the nipple than in adults. Even when increase in cardiac dulness cannot be made out, the heaving, forcible impulse, dull, heavy first sound, and the accentuation or re-duplication of the second sound point to incipient hypertrophy. In later stages temporary bruits are often heard over various parts of the heart. Sometimes they are merely hæmic, but at others they suggest temporary incompetence of the various valves and indicate failure of cardiac compensation.

For practical purposes signs of cardio-vascular hypertrophy may be regarded as constant in children suffering from this disease. But there may be apparent exceptions to this rule. For instance, a heart which is naturally smaller than the average may become very considerably hypertrophied and yet remain well within the limits of normal weight and thickness. I have notes of a necropsy on an adult female whose heart weighed only three ounces. Except that the great vessels looked disproportionately large the organ seemed in every way healthy. Such a heart might have increased its bulk fourfold and yet would not have been regarded as hypertrophied. A similar explanation may apply to cases in which the walls of the vessels do not appear to be unduly thickened.

Absence of dropsy, its causation and connexion with cardio-vascular hypertrophy and high arterial tension.—In all the fatal cases of interstitial nephritis which I have mentioned, with one exception, dropsy was said to be entirely absent; in the exceptional case it only occurred shortly before death and was apparently limited in extent. In an adult one is quite prepared to suspect the existence of nephritis, although there may not be the slightest sign of anasarca. But in a child all will agree that the outward and visible sign of nephritis is dropsy, and if this sign is absent one does not readily think of nephritis, although the symptoms may be precisely similar to those of the adult. Dropsy was absent in all but one of these cases, and it is within the scope of this paper to inquire why. As to the causation of dropsy, it is sufficient to say that the recent researches of Dr. Starling [8] have done much to confirm the view that dropsy depends on (1) difference between intra-capillary and extra-capillary blood pressure; and (2) on increased permeability of the capillary walls. In cardiac dropsy it is probable that increase of intra-capillary blood pressure, due to cardiac incompetence and subsequent venous engorgement, is the prominent factor. In renal dropsy it seems likely that increased permeability of the capillary walls due to lowering of their vitality and nutrition by the circulation of impure blood is the primary cause; whilst if such permeability is increased it is obvious that any excess of intra-capillary pressure will favour transudation or dropsy, and that it will be further favoured by stagnation of blood within the capillaries. To counteract the effects of increased permeability of the capillary walls intra-capillary pressure must therefore be kept low. Intra-capillary blood pressure may be lowered by general constriction of arterioles, the

[7] Goulstonian Lectures (1895), THE LANCET, March 23rd and 30th, 1895.

[8] The Arris and Gale Lectures (1896), THE LANCET, May 9th, 16th, and 23rd, 1996.

Hosted by Google

result of which will be to deliver less blood in a given time to the capillary area than usual. But such constriction will produce an enormous increase of labour for the heart. If the heart fails to meet it and becomes incompetent or dilated, backward pressure must occur in the veins; this will spread to the capillaries, and, given the fact that the permeability of their walls is increased, one may expect increased transudation or dropsy. Therefore, constriction of the arterioles alone is not sufficient to lower intra-capillary pressure by reducing the blood supply unless the heart remains competent. But, supposing the heart by becoming hypertrophied is able to meet the increased labour thrown upon it by constriction of the arterioles in front, the result will be that the blood supply from the arterioles to the capillaries will be reduced in volume. Its velocity will also be increased, for Bayliss and Starling[9] have shown that the result of general constriction of arterioles is the equivalent of plethora, whilst Cohnheim has demonstrated that in plethora the velocity of the blood is largely increased. It seems reasonable to suppose that transudation through damaged capillary walls will be lessened by the delivery of smaller volumes of blood at a higher rate of speed than normal into the capillary area, and also that stagnation in the capillaries which must naturally favour the occurrence of dropsy will thereby be prevented. In interstitial nephritis constriction of arterioles and increased force of cardiac action undoubtedly exist, and it may be that the absence of dropsy in this disease is due to the increase in velocity and diminution in volume of blood delivered to the capillary area thus produced.

In other words, cardio-vascular hypertrophy and high arterial tension are the direct antagonists of dropsy.[10] The clinical evidence of this is (1) that the initial dropsy of renal disease tends to decrease *pari passu* with increase of pulse-tension and hypertrophy of the left ventricle;[11] (2) that if the arterial tension remains low dropsy increases (Sansom); and (3) if, whilst pulse tension remains high, the heart does not become hypertrophied but dilated with incompetent valves, dropsy is again the result.

But what are the causes of cardio-vascular hypertrophy itself? The left ventricle enlarges because it has increased work to do owing to obstruction in front. The obstruction must to some extent occur in the capillaries if it be true that their walls are damaged by the circulation of impure blood. This is Dickinson's view. But the late Sir George Johnson always held that the obstruction was due to spasmodic contraction of the muscular walls of the arterioles and not to capillary resistance. It is obvious that such spasmodic contraction would produce high arterial tension and throw increased work on the heart, which accordingly would become hypertrophied. But what is the evidence that the arterioles are in a state of spasmodic contraction in nephritis? It is (1) that high arterial tension can be lowered in early cases where it exists by nitrite of amyl (Sir W. Broadbent); and (2) also that the muscular walls of the arterioles are found hypertrophied after death. This hypermyotrophy can only depend on the constant exercise of the muscular function of arterioles, which is to contract. Discrepancy as to the existence of hypermyotrophy of the arterioles may be explained by the fact that the muscular coats of vessels require prolonged staining before showing their characteristic structure. (For this observation I am indebted to Dr. T. Savill.) Increase of the fibrous tissues of vessels, which is also present but less marked than that of the muscular coats, may perhaps depend on congestion of the vasa vasorum. Few at the present day accept the view of Gull and Sutton that granular kidney is merely a part of a general arterio-capillary fibrosis affecting viscera and vessels alike. On the other hand, it is not disputed that such general arterio-capillary fibrosis may occur as part of senile degeneration. There is, therefore, evidence which warrants the belief that high arterial tension is due largely to muscular contraction of the arterioles, and that this leads both to hypertrophy of the left ventricle and hypertrophy of the muscular arterioles themselves; whilst it has been maintained that muscular contraction of the arterioles combined with increased force of cardiac action will have the effect of delivering small quantities of blood at a higher rate of speed to the capillary area, and thus transudation through unduly permeable capillary walls or dropsy will be lessened and intra-capillary pressure reduced. Thus cardio-vascular hypertrophy is nature's method of relieving and preventing dropsy. When it fails to occur or to be maintained dropsy is the result.

Why is dropsy early and extreme in parenchymatous nephritis, whilst it is late and usually insignificant or absent in interstitial nephritis? I take it that these differences depend chiefly on the natures of the two morbid processes. In parenchymatous nephritis the secreting portions rather than the stroma of the organ are affected, and the whole at once rather than successive portions. This must lead to enormous accumulation of poisons in the blood with corresponding damage to, and increase of permeability of, the capillary walls. But this is not all. High arterial tension prevails as much in parenchymatous as in interstitial nephritis. But in the former the resulting strain on the heart occurs before it has time to acquire sufficient force to meet it. As Sir W. Broadbent has pointed out, the cardiac phenomena of acute parenchymatous nephritis are those of acute dilatation.[12] Hence the resultant dropsy in early parenchymatous nephritis is partly cardiac, as is the case in its later stages. In interstitial nephritis, on the other hand, the secreting structure is only involved slowly, secondarily, and by degrees. Elimination is carried on for a lengthened period whilst polyuria prevails. Yet the blood must be impure and the arterioles resist its passage by becoming constricted. But the resistance is gradual and insidious as is the rest of the morbid process. The heart has time to acquire sufficient strength and becomes by degrees hypertrophied in order to meet the increasing labour thrown upon it. Finally, as in parenchymatous nephritis, the heart gives way, for compensation cannot go on for ever, and dropsy of the true cardiac type is the result.

Summary.—1. Toxæmia is present in all forms of nephritis. 2. The poison irritates and lowers the nutrition, thereby increasing the permeability of the capillary walls. 3. It also causes spasmodic constriction of the arterioles either by direct irritation or through the vaso-motor centres. 4. The result of spasmodic constriction of the arterioles is: (*a*) to reduce the capillary blood supply; and (*b*) to produce hypermyotrophy of the arterioles and usually in time of the heart. 5. If the heart is able to meet the labour thrown upon it, the velocity of the blood stream into the capillaries is increased, whilst its volume is lessened by constriction of the arterioles. These conditions of the circulation will tend to lessen transudation through the capillary walls, lower intra-capillary blood pressure, and therefore control dropsy. 6. If the heart fails to meet the demand, whether in early or later stages of renal disease, dropsy is maintained in the one case and produced in the other.

THREE CASES ILLUSTRATING THE IMPORTANCE OF A MINOR POINT IN THE ANATOMY OF FEMORAL HERNIA.

BY LEONARD MOLLOY, M.A., M.D. DUB,
HONORARY SURGEON TO THE BLACKPOOL HOSPITAL.

CASE 1. — The patient was a woman, aged seventy years, suffering from abdominal distress, uncontrollable vomiting, and consequent prostration. In her right groin I found a tumour the size of a pigeon's egg, and this I learned had appeared three days previously during a ride over bad roads in a landau. From the symptoms and the position of the tumour I concluded I had to deal with a strangulated femoral hernia, although on palpation and percussion the swelling did not present quite the usual features. It was not clearly tympanitic and felt doughy and solid over the more prominent portion, but on grasping that part of it which lay deep over the femoral ring a slight impulse could be felt on coughing. Some doubt was cast upon the correctness of the diagnosis by

[12] Transactions of the Royal Medical and Chirurgical Society, 1892, p. 123.

Hosted by Google

one of the two gentlemen whom I asked to assist me, but feeling confident I was right I decided to chloroform the patient and, if taxis failed, to cut down on the tumour forthwith. On doing this latter the main part of the swelling was seen to consist of an enlarged lymphatic gland, and my doubtful colleague was still more inclined to think I was on the wrong track. However, on drawing the gland aside I was able to display a small, deeply congested knuckle of intestine tightly gripped in the femoral ring; this, after examination, was returned to the abdominal cavity, and the operation was completed in the usual way.

CASE 2.—A woman, aged fifty-three years, had an acutely tender swelling in her right groin, which had appeared a few days previously; that portion of the tumour which was nearest the femoral ring was tympanitic, had a slight impulse on coughing and all the characters of a hernia, but the more prominent and tender portion was felt to be a solid body. Owing to the extreme tenderness reduction of the hernia was impossible without an anæsthetic, but on administering chloroform the bulk of the swelling was made to disappear with a characteristic gurgle, leaving, however, a tumour the size of a walnut still in the groin. On passing the finger underneath and so behind this the dilated femoral canal could be distinctly felt. Rest in bed and the application of anodynes restored the patient to her normal condition.

CASE 3.—A man, while endeavouring to close a heavy sliding door which had jammed, felt a pain in his left groin and a tender swelling appeared there. I saw the patient four days afterwards. He had on the left side over the femoral ring a tumour the size of a large walnut, extremely tender, but the skin over it in nowise inflamed; it was not tympanitic, had no impulse on coughing, and to the touch it appeared solid. It could be lifted away from the deeper structures by pushing the finger behind it, and by this manœuvre the femoral canal could be explored and was found to be distinctly dilated, and on pressing the finger into it, when the patient coughed, a knuckle of intestine could be felt to press into it and to strike against the finger-tip. Rest in bed and the application of belladonna extract and glycerine caused the tenderness to disappear and the tumour to shrink. Twelve years previously this man had been operated upon for a strangulated hernia on the right side. From the appearance of the old operation wound I should judge this hernia to have been femoral.

The interest in the foregoing cases lies in the fact that the disturbing element in the diagnosis in each instance was the enlargement of that lymphatic gland which Quain[1] says is constantly placed in the crural ring, which Gray[2] states occasionally fills up the interval between the femoral vein and the inner wall of the sheath, and by which Ellis[3] says the same interval is filled. With reference to this point Erichsen[4] speaks of the canal as usually containing a gland or two, while Treves[5] draws attention to the fact that an enlarged gland over or about the hernial sac often complicates matters. What the lymph supply of the gland closing the inner compartment of the crural sheath is seems to be uncertain; the efferent vessels of some of the superficial inguinal glands are said to pass through it, but it seems probable that in Cases 1 and 2 the enlargement was due to the irritation set up by the presence of a hernia in the canal. In Case 3 I am unable to account for it, seeing there was no lesion in the region supplying either set of superficial inguinal glands, except by supposing that before I saw the patient the knuckle of intestine which I could feel at the abdominal end of the canal had come down during his violent effort to close the door and given rise to sufficient disturbance of the surrounding tissues to cause the gland to enlarge, but had subsequently spontaneously become reduced, or that as a result of the effort one of the deep muscles in the region supplying the gland had been injured.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

COMPLETE LATERAL DISLOCATION OF FOREARM.

BY EDWARD SUTCLIFF, M.D., C.M. ABERD.

THIS being, I believe, a rare form of injury, the following notes, jotted down at the time, of a case which occurred a short time back in my practice may be of some interest. A stonemason, a strong and muscular man, but of spare habit, slipped and fell heavily on his right elbow and forearm, the inside of the former striking the curbstone. He was brought to my surgery within a very few minutes of the occurrence of the accident and before any swelling of the injured joint had supervened. Owing to this and to the fact that he carried no superfluous flesh the diagnosis was remarkably easy and clear. On examination the forearm was found to be somewhat flexed and semi-pronate, extreme deformity being produced by the excessive widening of the joint. The internal condyle was very prominent, almost protruding through the tightly-stretched skin, and the whole contour of the posterior and inferior portion of the trochlear surface of the humerus could be distinctly mapped out, giving the impression that there was little but skin and fascia between the finger and the surface of the bone. On the outer side of the joint the margin of the great sigmoid cavity was well defined and the fingers could be well dipped into its hollow. On rotating the forearm, which could be readily done to a moderate extent, the head of the radius was felt revolving in the orbicular ligament. By the aid of chloroform, making extension round my knee, and manipulating the joint, reduction was obtained without much difficulty. I had an opportunity of examining the joint a few weeks since, it being then six months after the receipt of the injury, and I found it normal in every respect. Motion was perfect, and the patient declared that he felt no inconvenience whatever in the performance of his accustomed work.

A CASE OF ANGINA LUDOVICI OCCURRING IN THE ACUTE STAGE OF SYPHILIS.

BY P. CLENNELL FENWICK, M.B. LOND., M.R.C.S. ENG., L.R.C.S. LOND.,
LATE SURGEON TO THE NEW ZEALAND SHIPPING COMPANY.

A FIREMAN, aged forty-eight years, was suddenly seized with pain in the head and vomiting, his temperature being 105·6° F., falling that night to 99·8°. There was a well-marked syphilitic rash all over the abdomen and a hard chancre on the penis. The temperature continued hectic till the third day, when the patient was apparently nearly well, complaining only of numbness in the limbs and weakness in the legs. There were no signs of typhoid fever or any pulmonary trouble. On the morning of the ninth day I was called at 7 A.M. by the night watchman, who stated that the patient's face had begun to swell at 5 A.M. I found him almost unrecognisable, the face and neck forming one hard, swollen mass extending from the sternum to the malar bones. There was no fluctuation and no emphysematous crackling in the tissues. The jaw was fixed and the tongue was pressed against the roof of the mouth, both speech and swallowing being impossible. The pulse was 140 and the temperature normal. The neck was packed in ice and stimulants were administered as far as possible. At 9 A.M. the patient was cyanosed, and could scarcely breathe. Tracheotomy was performed with great difficulty owing to great swelling of the tissues and the rolling of the vessel. The operation afforded great relief, but an hour later the increased swelling of the tissues forced the tube out of the trachea, and it was with great difficulty replaced. This accident happened again, and it was then found impossible to replace the tube, but the loss of blood having apparently relieved the œdema and congestion of the

Hosted by Google

trachea and larynx the patient was able to breathe naturally, though with great difficulty. He finally grew weaker and died at midnight.

The question is, was this a true case of angina Ludovici? I have searched the literature on this subject as far as possible and can find no mention of syphilis as one of the causes of this disease. In this case it was so markedly present that I could not help attributing the angina to this cause. It was quite impossible to make the lateral incisions in the swelling, as some writers recommend, but the median incision for the tracheotomy relieved him greatly. No post-mortem examination was possible. There was no history of insect bite, or wound on the neck, nor had the patient been working in the docks. Any bacteriological examination was of course impossible owing to the absence of staining reagents and even of a microscope.

Harley-street, W.

A CASE OF QUADRUPLETS.

BY EDWIN T. GOODE, L.R.C.S., L.R.C.P. IREL.

THE rarity of the occurrence of quadruple births encourages me to bring before the profession a few details of a case I have just attended. It was unfortunate that I was not called in earlier to the case, but the patient resided in a village two miles away and her mother hoped to be able to manage without the aid of a medical man.

On Jan. 22nd, 1897, the woman gave birth to two children, her mother being in attendance, and as the "afterbirth" did not come away satisfactorily I was sent for the next morning. On my arrival fifteen hours after the birth of the first two children I found the mother considerably blanched from loss of blood, and on examination a bag of membranes presented, which on rupture was followed by the birth of the third child. Again examining a fourth child could be felt, and this was born in due course. There were three distinct placentæ and four cords. The presentations were—the first a vertex, the second a footling, and the last two vertices. The children were all stillborn at between the fifth and sixth months. The commencement of labour was caused by the mother falling down. She has made an uninterrupted recovery. It was her third confinement.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

POPLITEAL ANEURYSM; LIGATURE OF THE FEMORAL ARTERY; RECOVERY.

(Under the care of Mr. F. PAGE.)

SUCCESSFUL ligature of the femoral artery for the cure of popliteal aneurysm has been recorded so frequently that it requires an explanation when such a case is published at the present day. We publish this one as a means of attracting the attention of our readers to the remarks by Mr. Page on the change in treatment suggested in the work to which he refers. The result of ligation of the artery in Scarpa's triangle is recognised by the profession as so very satisfactory that some good reason for changing the practice must be given. One of our greatest authorities[1] says that "the return of pulsation in the sac after the operation for popliteal aneurysm is by no means of frequent occurrence, yet it has been met with in some instances." This confirms the opinion of Mr. Page and agrees with our experience. We do not think that there is anything like the tendency to abandon this operation to the extent which is suggested, nor do we think it likely that an operation so easily performed as this, and which gives such good results, will be given up without better reasons, for one which is more difficult and involves the application of a ligature at a spot where the presence of the aneurysm may cause serious inconvenience from its encroaching on the area of operation, and where the artery is more likely to be diseased and the anatomical structure of the parts makes the operation more difficult even to the skilled operator.

A man, aged thirty-six years, was admitted on Nov. 21st, 1895, suffering from a large right popliteal aneurysm of some four months' duration. The patient had served in the army and contracted syphilis in 1880. His arteries were very atheromatous and both the aortic and mitral valves were extensively diseased. He complained of severe pain in, and about, the knee. On Nov. 23rd the artery was tied at the apex of Scarpa's triangle with a catgut ligature. The wound healed by first intention. A portion of the skin over the inner side of the great toe sloughed. The patient was discharged cured in January. In June the patient died from heart disease; there was no recurrence of the aneurysm.

Remarks by Mr. PAGE.—On page 659 of the "New System of Surgery," edited by Mr. F. Treves, it is stated: "Failure to cure the aneurysm, or so-called recurrent pulsation, is frequent" after ligature of the femoral artery at the apex of Scarpa's triangle. With all respect I demur to this statement. Mr. Syme, in the days of the septic ligature, tied the artery at the apex of Scarpa's triangle twenty-two times, and in every case the patient was cured. In the Royal Infirmary at Newcastle-upon-Tyne during the last eleven years the femoral artery has been tied at the apex of Scarpa's triangle for popliteal aneurysm twelve times, and all the cases but one were cured. Gangrene occurred in one, but gangrene is due to conditions the opposite of those which give rise to recurrence. If recurrence were frequent one would expect to find the condition dealt with frequently in the various London hospitals, but that does not seem to be the case, judging from the hospital reports. On the contrary, it is altogether exceptional, so far as I can ascertain. I have heard of recurrence after ligature, but in most instances pressure had been previously employed and failed. Mr. Pearce Gould, who writes the article on Aneurysm in Mr. Treves' book, makes the further statement: "Ligature of the highest part of the popliteal artery has been recommended of late, and in practice has been found very successful." I should much like to know the precise grounds upon which the statement that this method of treating popliteal aneurysm has been very successful in practice is based. It would seem to be an unwise thing to depart from a well-tried, simple, and successful operation upon any other than the most substantial grounds.

Cases of Popliteal Aneurysm treated by Ligature of the Femoral Artery during the Years 1885–1895 at the Royal Infirmary, Newcastle-on-Tyne.

LONDON FEVER HOSPITAL.—The annual meeting of the London Fever Hospital was held on Feb. 19th at the Hotel Victoria, Lord Balfour of Burleigh presiding. The report showed that during the past year 769 patients were admitted, including 637 cases of scarlet fever, 65 of diphtheria, 23 of measles, and 14 of German measles. The accommodation had been so fully occupied that it was necessary to refuse 184 applications for admission.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Surgical Physiology of the Foot.

A MEETING of this society was held on Feb. 23rd, Dr. HOWSHIP DICKINSON, President, being in the chair.

Mr. T. S. ELLIS read a paper on some points in the Surgical Physiology of the Foot. He referred to the view on which he had for many years been insisting—that the plantar arch was formed, was maintained, and, when destroyed, might be restored by renewal, in specially active degree, of the functions of the foot—i.e., by muscular action. Till recently, however, he had been unable to fully explain why the plantar arch was so rarely over-formed as the result of excessive action in the case of stage dancers. Excessive formation did sometimes occur as a morbid condition, as seen in pes cavus or claw-foot. The principal object of the paper was to show that the two features of the deformity which gave the alternative names were due to a common cause. A model in wood with the essential features of the human foot was shown in which elastic cords imitated the muscles which support the arch and act as "formators" of it, and those which control its formation, and act as "limitors." It was shown by this model that the combined flexor brevis and adductor hallucis acted not only (as so-called flexors) to hold down the first phalanx of the great toe, but also as "limitors" of the arch. Removal of cords imitating these muscles produced immediately hollow- *and* claw-foot, and at the same time the head of the metatarsal bone projected into the sole, a condition which in the living subject gives rise to painful callosities. The exaggerated arch was most evident in the middle line, because it was there that the weakened flexor brevis muscle arose. He thought that the condition might arise from a growing boy having boots too short for him, so that he found it more comfortable to walk on tip-toe. In this way the short flexors which normally depressed the arch were relaxed and the bowstring action of the flexor longus was increased. The foot was permanently held in the equinus position and the calf muscles served more and more as ligaments rather than muscles and became wasted. In order to correct the condition a very pronounced lengthening of the tendo Achillis was required, often to the extent of two inches. In the stage dancer the short flexors were specially needed to keep the great toe in a straight line, and these counteracted the excessive influence of the long flexors in tending to increase the arch. The fleshy mass of hypertrophied sole muscle filled up the hollow of the sole and produced an appearance of flattening. To sum up, hollow- or claw-foot was due to persistent action of the long flexor, with failure of the short flexor and adductor, while flat foot was due to failure of muscular action in both groups. Mr. Ellis insisted that the position of the hanging foot at rest was one of inversion, and maintained that there was loss of power and undue strain in walking with the foot everted and urged that the military march should be reformed. He maintained that the small toes even when encased in boots were of great use to break the shock of contact with the ground and to protect their corresponding metatarsal bones from pressure. The position of rest for the great toe was extension, the hallux lying somewhat over the second toe. If it be packed beneath the second toe it moved in a plane for which the joints were not adapted, and grinding of the cartilage and constant irritation were the necessary result. The toe became rigid, and owing to muscular inactivity flat-foot often ensued.

Mr. BARWELL thought some of Mr. Ellis's conclusions were open to controversy. The model, although extremely ingenious, could hardly be taken as representing the actual conditions in the foot. The action of the flexor brevis, with its extensive attachment to bone, could be but inadequately represented by a cord stretched between two points. He had found no tendency to flat-foot in dancers. It was true that the sole was filled up by muscle, but the instep was always high, indicating a good plantar arch. He did not think that a short boot would make a boy walk on tip-toe, but that it would cause crowding of the toes just like a narrow-toed boot.

Mr. DAVIES-COLLEY dissented from the view that the flexor longus threw the foot outwards. With reference to the muscles tending to depress the arch he thought that the muscles attached to the dorsum, especially the tibialis anticus and peroneus tertius and the extensors, were as important as the sole muscles. In some cases of pes cavus he had removed a piece of the tendon of the extensor proprius hallucis and fixed it to the base of the first metatarsal bone.

Mr. ELLIS, in reply, said that the action of the flexor longus hallucis could be demonstrated to throw the ankle outwards by putting the toes together and rising on tiptoe. With regard to the other controverted points he saw no reason to depart from the conclusions to which his investigations had led him.

MEDICAL SOCIETY OF LONDON.

Traumatic Neurasthenia.—Value of the Cystoscope in the Early Diagnosis of Renal Conditions.

A MEETING of this society was held on Feb. 22nd, Mr. C. B. LOCKWOOD, Vice-President, being in the chair.

Mr. VICTOR HORSLEY read a paper on the subject of Traumatic Neurasthenia. He pointed out that the symptoms of traumatic neurasthenia were essentially the same as those of neurasthenia from overwork. The cases fell into two classes—(*a*) those in which the symptoms began acutely and were mixed with general symptoms of concussion, and in which there were possibly some associated small lesions; and (*b*) those which were sub-acute and came on after a distinct interval. In the first group one of the most striking symptoms was the irregular pyrexia which was almost always present. The rises of temperature were often sudden and might go as high as 111° F. In one such case the attacks of pyrexia were accompanied by delirium and hallucinations. The pyrexia differed from that due to coarse cerebral lesions in being at once controlled by sponging. Even after a patient had apparently recovered any nervous shock or excitement might again cause similar attacks of pyrexia. In the second group of cases the latent period was usually about a week, but might be two or three. The symptoms, as pointed out by Dr. Hughlings Jackson, were of two kinds, which often occurred together—viz., those due to diminished functional activity (general weakness, localised paralyses, and anæsthesiæ), and those due to over-action (contractures and pains). In traumatic cases the localised paralyses were usually on the left side and almost always affected the lower limb; but one unusual case was mentioned in which there was paralysis of the muscles of the chest on the left side. One of the most common sites of spasm was the tongue, which in functional hemiplegic cases was usually drawn over to the opposite side, a point of great importance in diagnosis. There were often also contractures of the limbs. Anæsthesia usually began in the upper limb on the post-axial border, a position in which it also occurred, as shown by Dr. Ormerod, in overworked sempstresses. The characteristic sites for pain were: (1) painful pressure sensations at the bregma; (2) shooting occipital pain along the supply of the second cervical root, often accompanied by a clicking sensation; (3) infra-mammary tenderness; (4) tenderness and pain made worse by movement or jarring at the dorso-lumbar junction; and (5) tenderness and aching over the sacrum and posterior superior iliac spine. The knee-jerks were much exaggerated at first, but later diminished and might even be lost. Ankle-clonus might also be present in neurasthenic cases. There was usually increased quantity of urine, with lowered specific gravity. He had never detected sugar or albumin. There was nearly always increased frequency of micturition, but he had never seen retention. Although it was usually easy to detect wilful malingering, it was always difficult to know how far there was unintentional exaggeration as one of the symptoms of the neurasthenia itself, and there was often room for much difference of opinion. In many of the cases recovery was ultimately complete, but there was a great tendency to relapse. The most obstinate symptoms were anæsthesia of the special senses, such as hemianopia, deafness, and loss of tactile localisation. In one case, in which after a blow on the occipital region a patient had left hemianæsthesia and left hemianopia, no lesion could be found when the patient ultimately died. Pain, especially the dorso-lumbar pain, was also very persistent. The most successful

Hosted by Google

treatment was on the lines of the Weir-Mitchell treatment: isolation, at any rate for the first month; massage, general and local, for six weeks, and over-feeding. Where this treatment could not be employed simple tonics might be given, but the improvement would be much slower. In conclusion Mr. Horsley urged that in all cases of this kind which came to litigation the medical men concerned should always have a consultation beforehand, so as to avoid an unseemly conflict of evidence in the witness box.—Mr. SPENCER WATSON remarked that these symptoms did not occur unless there was neurotic predisposition. He inquired if there were any special changes in the urine during the pyrexial stage.—Dr. CHURTON said that cases of this description were common among miners, and in most of them there had been previous blows on the back from falling coal. He confirmed the statement that the knee-jerks might be lost.

Mr. HURRY FENWICK brought forward a series of twenty-one cases of Nephrectomy with two deaths to demonstrate the value of the cystoscope in detecting early stages of malignant and tuberculous disease of the kidney. He gave two illustrative cases of malignant disease being removed six weeks and three months after the onset of profuse hæmaturia. The disease was localised by seeing through the cystoscope blood issue from one ureter. He referred to cases of calculous pyelitis in which the cystoscope showed pus issuing from one ureter. He advised nephrectomy for tubercle before the stage of sclerosing peri-nephritis had set in, and then only when the lower organs were free from the same disease. If the kidney was densely attached by a thick, firm layer of gelatinous adhesions (a characteristic of a later stage) it would be safer and better to leave it. He believed that those tuberculous kidneys in which the ureters were blocked with tubercle would give the best results in nephrectomy, for the obstructed ureter virtually confines the disease to the kidney in these cases for comparatively long periods of time. When there was at all extensive tuberculous disease of the bladder he thought supra-pubic cystotomy was of little service.—Mr. LOCKWOOD thought that general surgeons were getting to use the cystoscope habitually just as physicians used the ophthalmoscope. He mentioned cases showing its value in indicating the side of the renal disorder. He thought that he had seen cases of tuberculous disease of the bladder relieved by supra-pubic cystotomy. Mr. G. R. TURNER also believed that he had seen good result in one case in which there was a single ulcer, apparently tuberculous.—Mr. HORSLEY said that he had regretted operating on two cases of tuberculous disease of the bladder and thought it was generally inadvisable. He asked whether Mr. Hurry Fenwick found it necessary to make an abdominal incision and introduce his hand for purposes of exploration as recommended by Mr. Knowsley Thornton.—Mr. HURRY FENWICK, in reply, said that single ulcers of the bladder were rarely tuberculous. He had not seen any good from scraping and drainage in any cases that were at all extensive. He considered Mr. Knowsley Thornton's double incision unnecessary.

HARVEIAN SOCIETY OF LONDON.

The Dangers and Diagnosis of Breech Presentation and its Treatment by External Version towards the End of Pregnancy.

A MEETING of this society was held on Feb. 18th, Dr. MILSON, President, being in the chair.

Dr. HERBERT SPENCER read a paper on the Dangers and Diagnosis of Breech Presentation and its Treatment by External Version towards the End of Pregnancy. He stated that since the days of Hippocrates the dangers of birth by the breech or feet had been recognised. He gave statistics showing that from nearly one-fifth to nearly one-half of the children delivered in this manner were stillborn. He discussed the causes of the high rate of mortality and the injuries (fatal and non-fatal) to which the child was exposed in this mode of delivery, and he described in detail the method of diagnosing presentation of the breech by abdominal palpation. Dr. Spencer advocated the abdominal examination of all patients at the seventh month of pregnancy, and the treatment of breech presentation by external version at seven and a half months, followed by the wearing of an abdominal belt. He mentioned six cases which he had treated in this way, and in which the children were born as vertex presentations and survived, and twenty-six cases similarly treated in Dr. Pinard's clinic with one immediate infantile death, two other children subsequently succumbing, and he urged a further trial of this little operation, which was very easy, safe, and painless, and had few contra-indications.

Mr. H. C. PHILLIPS mentioned a case of breech presentation in which there were imperforate anus and hydrocephalus which rendered diagnosis of the presenting part difficult.

Dr. DUTCH suggested that in cases where the cord was short and twisted round the fœtus there might be a risk on manipulation of detaching the placenta, thus exposing the patient to the danger of accidental hæmorrhage.

Dr. COCK mentioned that he had twice performed the operation successfully at the eighth month. He had been led in each case to make an external examination and found that the presentation was a breech one and that the head was against the liver, and that as the uterus contracted the hard head compressed the tender liver against the ribs and caused the considerable pain for which his patients had consulted him. The external version had been of the easiest description and the subsequent presentation at birth had been of the head.

Dr. BOXALL pointed out that in estimating the mortality of breech presentation it was important to bear in mind that frequently some underlying condition existed which favoured presentation by the breech in preference to the vertex. Such, for instance, occurred in minor degrees of contraction of the pelvis, in placenta prævia, and in some cases of fibroid and ovarian tumours, which conditions in themselves tended to increase the mortality apart from the presentation. Dr. Boxall fully endorsed Dr. Spencer's opinion as to the value of systematic examination of the abdomen, not only in breech labours, but also in other obstetric cases, and considered that to obtain the full benefit of such examination it should be undertaken before examination *per vaginam*.

Dr. AMAND ROUTH emphasised Dr. Spencer's method of abdominal palpation by the flat of the hand instead of the finger tips. The hands and the abdominal wall must move together over the fœtus *in utero*. He had recently diagnosed at the eighth month a case of breech presentation with one if not both legs extended. He asked if Dr. Spencer would advise external cephalic version, and if so, how the extension of the legs could be overcome. He congratulated Dr. Spencer on his successful efforts to familiarise the profession with abdominal diagnosis and treatment.

Dr. HANDFIELD-JONES agreed with Dr. Spencer's main contentions, but thought that mortality percentages based on maternity returns were too high.

Dr. GOW quite agreed with Dr. Spencer's suggested method of treatment, although he did not believe that when properly conducted the mortality in breech deliveries was as high as that stated by Dr. Spencer. The chief practical difficulty would be to induce patients to present themselves for examination between the seventh and eighth months of their pregnancies.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.

The Climatic Treatment of Phthisis.

A MEETING of this society was held on Feb. 10th at Limmer's Hotel, Conduit street, W., Dr. MYRTLE being in the chair. Twenty-four new members were admitted to the society.

Dr. W. V. SNOW read a paper on the Climatic Treatment of Phthisis, in which he referred to the value of the climate of South Africa in the interior and the necessity of better accommodation and sanitation and food; the superiority of mountain climates; the value of a voyage up the Nile for the wealthy; the good results of sea voyages; the climate of New Zealand; the mistake so frequently made of sending patients in an advanced stage of the disease to Australia; and the possibility of carrying on the open-air treatment, both in winter and in summer, in England.

Dr. THEODORE WILLIAMS considered that the benefit which sea voyages ought to produce was largely lost on account of the want of exercise, which led patients to gravitate to the smoking-room, and that often became practically a drinking-room. He believed that results as good as, if not better than, those afforded by many foreign

Hosted by Google

places to which phthisical patients were sent might be obtained by the more thorough employment of the open-air treatment in English resorts.

Dr. BAGSHAWE spoke of the danger arising from subsoil moisture in connexion with some of the resorts in the South of France, where the presence of decaying vegetable matter constituted an additional danger. It was well, therefore, to advise patients to go to modern villas and hotels on the hillsides in those places.

Dr. HERON doubted if an exceptionally large number of bad cases were sent to English health resorts or of good ones abroad. A cold winter climate was undoubtedly the best for young patients who could take active exercise and lead an out-of-door life. He quoted the experience of Hudson Bay life in support of this. Patients, he thought, went to the Riviera, with its delightful climate, to slide down to the grave as quietly and comfortably as they could; he did not think that life there was calculated to cure tuberculosis.

Dr. LAING GORDON gave his experience of the disadvantages to be encountered in the South African resorts, and discouraged the sending of phthisical patients there haphazard and without proper instructions.

LIVERPOOL MEDICAL INSTITUTION.

Operation versus Glasses for Squint.—Litholapaxy in Children.—Tubo-ovarian Abscess,—Fibrinous Rhinitis.—Permanent Cure of Nasal Duct Obstruction.

A MEETING of this society was held on Feb. 11th, Dr. RICHARD CATON, President, being in the chair.

Mr. RICHARD WILLIAMS read a note on the Importance of Treating Squint by Means of Operation. He pointed out that the routine practice of ophthalmic surgeons was to give glasses in cases of squint; his practice was to correct any errors of refraction with glasses in squint cases, but he drew a marked distinction between giving glasses for errors in refraction and giving glasses for squint. He never ordered glasses for the squint itself, but always operated. As a defence of this practice he said that there were many cases of squint in which no errors of refraction could be found. To give glasses in these cases was, he considered useless. He further said that the annoyance of having to wear glasses was greater than the annoyance of a simple operation, which was sure to be successful.—Mr. SHEARS said that in young children with convergent squint, where one eye was markedly defective in vision and in fixation, the majority of surgeons were possibly over-cautious in refusing to operate under the age of six years for fear of divergence resulting. When, however, the squint was alternating, and the vision good in each eye, he would hesitate to operate even though the hypermetropia was very small in amount. The immediate operation would avoid the many inconveniences of spectacles, but he had sufficient faith in Donders' theory of squint to first try the effect of glasses.—Mr. EDGAR BROWNE said that to treat all cases of squint by operation was to disregard all the advance of the past few years. Squint was primarily an attempt on the part of the nervous system to compensate for a structural or functional defect in the peripheral sense organ. Cases of concomitant squint presented three stages: (1) the periodic, (2) a period when one eye was definitely selected for fixing and squint apparent but not necessarily permanent, and (3) when the squint had become the position of rest. Cases in the first stage must not be operated on. In the second stage operation might be performed, but many would not need it if sufficient care in treatment could be exercised. In the third all cases must be operated on.

Mr. R. W. MURRAY related five cases of Litholapaxy in Children, the ages of the patients ranging from two years and ten months to twelve years. The results had been extremely satisfactory, and he warmly advocated a crushing rather than a cutting operation for stone in children.—Dr. RAWDON said that his experience of litholapaxy in children was limited to two cases, both little girls, aged five and eight years respectively; both cases were highly successful. He had more experience in lateral lithotomy in children, and had performed the operation sixty-seven times with two deaths. He felt, however, that in a few years the operation recommended by Mr. Murray would come to be regarded as the best general operation for stone in children.—Mr. LARKIN said that he had for some years considered that litholapaxy was the true method of removing stone from the bladder, and that only exceptional circumstances could justify any other operation. It was not a difficult operation when the stone was of the size usually met with in this country and the parts were fairly normal.

Dr. J. E. GEMMELL read notes of a case of Double Tubo-ovarian Abscess in which he had performed abdominal section. The disease had commenced in the Fallopian tube; there was occlusion of the fimbriated end of the tube, as it was glued firmly to the ovary. There was a history of occasional discharge of pus from the uterus, pointing at an attempt at drainage through the uterus.

Dr. HUNT read notes of four cases of Fibrinous Rhinitis to illustrate its relation to diphtheria. In one patient it was followed in three weeks by an attack of true diphtheria; in another it came on a month after faucial diphtheria whilst the paralytic sequelæ were still present; in a third instance two persons living in the same house with the patient were subsequently attacked with diphtheria. He thought the disease was in most cases only a modified form of diphtheria in which the local symptoms were present without the systemic poisoning, for in over 50 per cent. of all cases the Löffler bacillus had been found in the membrane.

Mr. BICKERTON read a paper on the Permanent Relief of Nasal Duct Obstruction. He gave a historical sketch of the treatment of the affection from very early times down to the present date, and described a modification he had made in a certain form of style which could be worn by the patient permanently for the relief of the distressing symptoms.—Mr. SHEARS held the opinion that long-standing obstruction of the nasal duct was incapable of cure in the true sense of the word, but that in a fair proportion of cases treatment by probes (and especially by prolonged irrigation with antiseptics through a hollow tube) so far relieved the symptoms that the fluid in the sac became quite clear, and the running over of tears only took place when the eye was subjected to strong stimulation.—Mr. R. J. HAMILTON thought that there was no cure, only a relief, from the most distressing symptoms by the continuous use of these styles. A patient under his observation kept her nasal duct open by passing a probe herself about once a month, and had been doing so for about fifteen years. He thought many of these chronic cases might be taught this accomplishment without any risk.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

Removal of the Uterine Appendages.—Exhibition of Specimen.

A MEETING of this society was held on Feb. 17th, Dr. MUTCH, Vice-president, being in the chair.

Mr. CHICKEN opened a discussion on the Indication for and Results of Removal of the Uterine Appendages. He said that this operation should not be undertaken unless there is no possibility of otherwise curing the woman. He thought the conditions under which it might be performed were: (1) whenever such coarse disease exists in ovary or tube so as to destroy entirely their function; (2) where affected by malignant disease; (3) to induce an artificial menopause in certain cases; (4) as a means of preventing conception when the pelvis is contracted; and (5) in certain cases of fibroids of the uterus. He thought the operation should not be performed for simple inflammation of tube or ovary, and he expressed strong disapproval of Tait's dictum, which stated that both ovaries should be removed where only one was diseased. He thought hernia not infrequently followed the operation because the abdomen was opened through the linea alba; he recommended an incision, not median, but through the rectus muscle.—Dr. MICHIE advised the operation for all those cases where the tubes contained pus, as in this event resolution did not take place; also in hydro- and hæmato-salpinx and in tubal gestation the operation should be performed without delay. For the arrest of the growth of myoma of the uterus it should be performed, but in these cases care must be taken to remove all the ovarian tissue. He had undertaken this method of treatment for uterine myomata in about fifty cases, and in all except two had had a favourable result. It should be carried out for

Hosted by Google

some forms of infantile uterus where intense pain occurred at the menstrual periods. He further drew attention to the frequent presence of the alcoholic habit in persons who suffer from uterine disease and thought that this habit was responsible for some of the failures which were often attributed to the operation. — Dr. TRESIDDER thought there would be a general agreement that the operation was not only justifiable, but should be performed where coarse disease of the ovary or tube existed. He thought where the operation was done for nervous affections, such as hystero-epilepsy, little good resulted; even for uterine fibroids he thought it was still an open question what the nature of the results was. He certainly thought the results generally obtained were not so good as those of Dr. Michie, which gave 96 per cent. favourable. He differed from Dr. Michie that the menopause artificially produced presented no material distinction from that occurring physiologically, as he thought the nervous disturbance in artificial menopause was much more profound, dread of impending evil being a marked feature.—Miss GRAY drew attention to the fact that the effect of the operation was not immediate either in the production of the menopause or in its curative effect; disappointment was often the result of not being aware of this. — Dr. BLURTON also emphasised this fact. — Dr. ROTHERA related a case where the beneficial effects of waiting before resorting early to operation was exemplified, the fibroid sloughing and being expelled. He further related two cases where the operation was a failure. In one the patient was now bedridden; in the other, performed for menorrhagia, no benefit followed. He further thought that the induced menopause differed vastly in its nervous effects from the physiological.—Mr. O'MULLANE and Dr. BOLTON related cases.—Dr. MUTCH agreed with Dr. Michie that alcoholism was responsible for some of the failures of this operation.—Mr. CHICKEN and Dr. MICHIE replied.

Dr. MICHIE showed a Pregnant Uterus that he had removed ten days before affected with myoma which had become impacted in the pelvis. The patient made a good recovery. The operation was performed by the abdominal method and the entire organ was removed.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Porro's Operation.

A MEETING of this society was held on Feb. 11th, the President, Mr. RECKLESS, being in the chair.

Dr. SORLEY related notes of the following cases: (1) Abscess of the Liver; (2) Cancer of the Pleura and Lung; and (3) Concurrent Scarlet and Enteric Fever.—The PRESIDENT, Dr. BURGESS, Mr. LOCKWOOD, and Dr. RICHARDS discussed the cases.

Dr. KEELING related a successful case of Porro's Operation and showed the uterus and ovaries which had been removed. The particulars were as follows. The patient, thirty-five years of age and married for about three years, was a rather small, slim woman, but except being very deaf was in good health and not at all deformed. Her first child was born in January, 1895. Labour was normal and no peculiarity about the os externum or cervix was noticed. The term of her second pregnancy was completed in August, 1896, and on the 23rd of that month she fell in labour. During the previous week she had symptoms of eclampsia and four convulsive fits occurred three days before labour. Relief was obtained by purgatives and bromide and the convulsions ceased. On the day of labour pains began about 7 A.M. and continued through the day. In the afternoon the medical man, a skilful and experienced accoucheur, was summoned. On examination he could find absolutely no trace of the os or cervix. Dr. Martin of Sheffield was sent for, but his examination proved equally fruitless. Towards midnight Dr. Keeling was summoned and he also failed to find any external os. An anæsthetic was then given and the whole hand introduced into the vagina, and at last a dimple surrounded by a slight ridge was made out. This was believed—as it proved correctly—to indicate the position of the os and cervix, and an attempt was made to open the os with a sound, the uterus being steadied from above and pressed down towards the pelvis. This expedient apparently succeeded, and first the tip and then the whole of the forefinger was passed, but it was soon evident that an entrance had been made, not within the cervix, but behind it into the peritoneal cavity. In this emergency it was decided that the safety of the patient would be best consulted by Cæsarean section, and she was carefully moved for this purpose to the Jessop Hospital, a distance of four miles. Consent of the patient and husband being given and the staff assembled, the operation was commenced with the intention of its being limited to Cæsarean section by Sänger's method. The abdominal and uterine incisions were made in the usual way. The placenta was found immediately beneath the uterine wound, and as soon as it was reached the hand was slipped between it and the wall of the uterus and the child seized by the leg. Both child and placenta were extracted without difficulty. Hæmorrhage at this moment was free, but scarcely excessive. The cavity of the cervix was then opened into the vagina and the ovaries excised. Up to this point Cæsarean section only had been contemplated, but the atony of the uterus was so marked and the continuous oozing of blood so great that it was thought better to complete by Porro's method. The remainder of the broad ligament on each side was accordingly secured by fine catgut, then a strong double ligature of the same material was passed through the cervix, each half of which was tied separately, and then the two halves as a whole by another loop of ligature. On each side of the cervix one end of the ligature was left long for after use. The uterus was then cut away obliquely so as to form a front and back flap, the bottom of the cup-shaped wound was scraped, iodoform was freely applied, and the flaps were sewn together. The stump was then drawn into the lower angle of the abdominal wound and secured by the ligatures left for the purpose; these were passed through the parietal peritoneum, but not through the skin. An additional stitch between the parietal peritoneum and the stump was inserted on each side, and in closing the abdominal wound the lowest silkworm suture was also made to take a hold of the peritoneal covering of the stump. The rest of the abdominal wound was closed as in ovariotomy. No drainage was used at first, but a gauze chain was found useful at a later stage. Rigid antiseptic precautions were of course observed throughout. For a few hours after the operation the condition of the patient was very critical. She then rallied and afterwards made an excellent recovery. The temperature never rose higher than 101·2° F. and by the eleventh day it had fallen to normal. As the stump wasted a deep hole formed, from which the discharge was abundant and offensive; the rest of the abdominal wound healed straight away. Two ligatures from the broad ligament (each with a small slough) came away, one on the twenty-first and the other on the twenty-sixth day after operation. The thick ligature round the cervix was not again heard of. The deep sinus at the lower angle of the wound had completely closed seven weeks after the operation and the patient left the hospital a fortnight later. The cicatrix had remained firm, and there was at present no sign of hernial protrusion. Mother and child were quite well. After detailing the case Dr. Keeling briefly discussed the questions of complete occlusion of the os externum in labour, the justifiability of the operation which had been undertaken, the respective merits and applicability of Sänger's Cæsarean section, Porro's operation and laparo-elytrotomy, and defended the method of dealing with the stump which had been employed in this case.—The PRESIDENT and Mr. PYE-SMITH made remarks.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Rapid Absorption of Tuberculous Masses in the Abdomen.—Blockage of the Common Duct by a Gall Stone.—Cerebral Injury.—Implantation Cyst of the Iris.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Feb. 5th, Mr. J. W. TEALE, President, being in the chair.

Dr. CHURTON showed three cases of Rapid Absorption of Tuberculous Masses in the Abdomen. 1. A boy, aged ten years, was admitted into the Leeds Infirmary on Aug. 26th, 1896, with ascites. His parents were very poor. The treatment was by rest, good food, and one grain of iodoform with gentian extract every four hours; the abdomen was painted with tincture of steel. On Sept. 20th the fluid was all gone, but two thick masses remained, one extending from the left

Hosted by Google

costal margin to the umbilicus, and the other in the right lower epigastrium. On Nov. 12th the size of the mass (which then extended from the left costal margin to a point two and a half inches to the right of the umbilicus and was oblique and curved, with the convexity downwards) was 8 in. by 2 in. by (?) ¾ in. On Feb. 1st, 1897, there was only a very small area of thickening above and to the right of the umbilicus. 2. A woman aged thirty-seven years, was admitted on Aug. 4th, 1896. Her temperature during the first week averaged 98°F. in the morning and 102° in the evening. Similar treatment was followed out as in the first case with the addition of one ounce of quinia mixture (five grains) three times a day. On Sept. 7th the ascites had disappeared. The patient had never looked ill; the disease was localised in the abdomen. She had lived in a damp house on a farm and drank much unboiled milk. On the 12th the patient went home. On Oct. 25th the abdomen began again to enlarge. On Dec. 8th she was re-admitted. On the 12th she was tapped and 440 ounces of serum fluid were withdrawn. The former treatment was resumed. A mass, the size of two small closed hands, in the mid-abdomen was found. By Feb. 6th, 1897, the mass had gradually and entirely disappeared. She took two grains of iodoform and three grains of gentian extract every four hours, and one ounce of quinia mixture (three grains) three times a day during her stay in the hospital. 3. In a man lately under observation, less favourably placed and less healthy, the absoption of a similar mass occupied nearly a year.

The PRESIDENT described a case that had been under his care of a lady, aged seventy years, who after general malaise and colic for a fortnight was laid up with complete jaundice, which was diagnosed as a blockage of the common duct by a Gall Stone. After five weeks, as the general health was giving way, an operation was decided on after a consultation with Mr. Pridgin Teale. On the day it was to be performed the patient begged off, as she was certain some change had taken place and that the gall stone had changed its position. It was decided to wait, therefore, and there was a marked increase of bile in the motion. A fortnight later, after severe rigor, intense pain followed first by local and then general peritonitis set in, and death seemed imminent; but she rallied under opium and the third motion afterwards was full of bile. Unfortunately the one in which it is assumed that the gall stone passed was not examined owing to the critical state of the patient. From that time she made a steady but gradual recovery and is now quite well and walking about out of doors. There was complete blockage for eight weeks and three days.—In the lengthened discussion that took place and which turned on the indications for operative interference in such cases the following gentlemen joined:—Mr. PRIDGIN TEALE, Dr. BARRS, Dr. CHURTON, Dr. GRIFFITH, Dr. GORDON BLACK, and Mr. LITTLEWOOD.

Mr. E. SOLLY read the notes of a case of Cerebral Injury presenting certain unusual features. A lad aged nine years fell from a wall about 8 ft. high on to the ground falling probably on the back of the head. He was able to walk home a distance of about a-quarter of a mile without assistance but shortly afterwards became gradually drowsy. Some slight convulsive movements were noticed but unfortunately no definite observation was taken of them. The family medical attendant then arrived and finding the symptoms of coma developing, telegraphed to Mr. Solly to come and bring trephining instruments, as he supposed the case to be one of meningeal hæmorrhage. In the interval of about forty minutes before Mr. Solly's arrival the patient gradually began to show signs of returning consciousness, and all idea of immediate operation was negatived. The patient, after passing through a stage of "cerebral irritation" lasting a few days, made a gradual but steady recovery, and is now quite well and strong, exhibiting no sign of cerebral lesion whatever. Mr. Solly commented on the fact that the supervention of coma after an interval of consciousness following a head injury was generally taken as evidence of meningeal hæmorrhage, and for such trephining was generally held to be the proper treatment with a view of securing the damaged vessel. This case he considered worth quoting as showing that the symptom, at any rate in children, did not point to the absolute necessity of surgical interference.

Dr. WHITEHEAD read notes of a case of Implantation Cyst of the Iris in a man aged twenty-nine years, upon whom iridectomy had been performed in India five months previously. The cyst formed within a period of three months and caused glaucomatous symptoms. Tapping the cyst and removal of a portion of the cyst wall failing to afford relief the eyeball was enucleated. A microscopical examination showed that the cyst was lined with laminated epithelium, and originated in the implantation of a portion of corneal epithelium in the substance of the iris during the performance of the operation of iridectomy.

The following cases and specimens were shown:—

Mr. NUNNELEY: A Case of Acromegaly with Bi-temporal Hemianopsia and Incomplete External Ophthalmoplegia.

Mr. MAYO ROBSON: Patient from whom the whole of the upper jaw and the nose were removed a year previously for Rodent Ulcer.

Dr. BRAITHWAITE: Uterus removed entire for Fibroid Disease.

Dr. BRONNER and Dr. LOCKWOOD: A Case of Cerebral Abscess of aural origin operated on eighteen months previously.

Mr. WARD: (1) Sacculated Aneurysm-like Tumour on Saphena Vein; and (2) Part of Calcified Wall of an old Empyema.

Dr. BARRS: (1) Raynaud's Disease: and (2) Multiple Rheumatic Myositis.

Dr. MANTLE: Heart showing Ulcerative Endocarditis, the patient dying from Embolic Hemiplegia.

MIDLAND MEDICAL SOCIETY.

Exhibition of Cases and Specimens.—Auditory Hallucinations.

THE sixth ordinary meeting of this society was held on Feb. 17th, Dr. SHORT being in the chair.

Mr. PROSSER showed a woman, aged seventy years, who for many years had suffered from a Pulsating Tumour in front of the Right Outer Ear. The diagnosis of aneurysm of the internal carotid artery had been made and the right common carotid had been ligatured some time back. The pulsation disappeared after the operation and the swelling decreased, but before very long both re-appeared and have now been stationary for some years. At one time considerable hæmorrhagic oozing occurred from the swelling, but was controlled by the local application of styptics.

Mr. HEATON showed an infant, aged fourteen months, with a Swelling in the Left Side of the Perineum just in front of the anus. The left testis was absent from the scrotum, which latter was undeveloped on that side. The case was an illustration of the somewhat rare deformity of ectopia testis, as distinguished from undescended testis. He proposed to dissect up the organ from its abnormal position and fix it in the scrotum, an operation which he had done with success in a similar case two years ago.

Dr. GANNER showed a Pendulous Polypoid Tumour springing from the wall of the duodenum about five inches below the pylorus. It had dragged the peritoneal coat into the stalk in the form of a narrow funnel about half an inch in depth. The elongations of the tumour were probably due to the intestinal contractions. It was removed in the dissecting-room from the body of a man aged forty-nine years.

Dr. KAUFFMANN showed a Liver containing a solitary Retention Cyst near its Upper Surface. The cyst was limited by a layer of epithelium and the wall showed signs of dissepiments; the contents were about one and a half ounces of thin, blood-stained fluid. It was regarded as a retention cyst due to cicatricial obstruction of part of the bile-carrying apparatus.

Mr. PIETERSEN read a paper on Auditory Hallucinations. After a short review of the psychology of auditory hallucinations Mr. Pietersen referred to their occurrence in mental health and showed that the limit of health might be determined by their effect upon the conduct of the individual. A clinical review followed of auditory hallucinations, their characters, and mode of occurrence. The facial signs of obscure hallucinatory cases were referred to, and stress was laid on the impossibility of giving a definite prognosis in all cases of this sensory disorder.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Pressure in the Growing Pregnant Uterus.

A MEETING of this society was held on Feb. 10th, Dr. MILNE MURRAY and afterwards Dr. BARBOUR, in the absence of the President, being in the chair.

Hosted by Google

Dr. R. C. BUIST showed a Velamentous Placenta.

Dr. J. W. BALLANTYNE showed: (1) an Anencephalic Fœtus, and (2) a Congenital Fibroma from the Scalp of a new-born Infant, which was about the size of the thumb of the child and was excised a week after birth with a successful result. Microscopically it consisted of sebaceous glands and fibrous tissue.

Dr. MILNE MURRAY showed his modification of the Axis-traction Forceps with improvements in the method of detaching the traction rods and also in the position of the joint of the traction handle.

Dr. MILNE MURRAY also read a paper on Is there a Positive Pressure in the Growing Pregnant Uterus? It was suggested by a discussion at the December meeting of the society on the deviation of the pregnant and puerperal uterus. The physical relation of the growing pregnant uterus might be best realised by regarding it as a sac enclosed within a distensible capsule, which was composed of the abdominal walls, the diaphragm, and the pelvic floor. Assuming the intra-abdominal pressure to be neutral at the commencement of pregnancy, the uterus as it grew would require to push aside or lift up the viscera, and a gradual increase of the intra-abdominal pressure would result. This increase of pressure could only be obviated if the abdominal muscles underwent physiological enlargement to the same extent as the enlargement of the uterus. The anterior walls bulged obviously; and the question was, Did this bulging occur with the same tension as in ordinary circumstances, or during pregnancy was this bulging attended with increase of tension due to increased pressure behind them? That this tension was increased was evident by different facts: the fœtal head in all primiparæ and in many multiparæ was kept in position in the pelvis by the tension of the resisting abdominal muscles; the walls in the majority of cases became thinner as pregnancy advanced; the presence of striæ gravidarum or cracks; the discomfort due to even slight degrees of flatulence in the compressed intestines; the shallowness of the respiration showing the diaphragm was impeded in its action; and the projection of the pelvic floor. Before the commencement of pregnancy the cavity of the uterus was only a potential sac, its walls being in close apposition. With the arrival of the ovum it became an actual cavity, and by the time it had undergone sensible increase of its size the cavity was lined by a closed membranous sac in which its contents lay. Separation of the walls could only be effected by a pressure on the part of the ovum greater than that of the extra-uterine region. The only state by which the walls of the growing uterus could be in the condition of a flaccid sac devoid of positive internal pressure would be if the cavity of the abdomen were opened and the uterine walls grew in area at a rate greater than the development of its contents in bulk. But, as this consideration was absent, it seemed self-evident that a positive pressure must exist in the sac of the ovum, otherwise the growth of the sac against the abdominal pressure would be a physical impossibility. Until recently no one had had any doubt but that the contents of the pregnant uterus filled its cavity and that its walls were in a sense tight over them. Doubt had been raised because it has been observed that the walls of a pregnant uterus removed from the body were loose and flabby; but the walls of such a uterus had lost their vital tone and were, like other dead muscle, relaxed and lengthened. If living voluntary muscle was cut across its ends separated; if a dead muscle was divided no such gaping occurred. The living uterus might be tense while the dead was flaccid. The evidence that seemed to have had most effect in changing the opinion of some had been derived from the observation of frozen sections; but it was of paramount importance in estimating the value of any evidence derived from this source that the tissues were dead and that the muscles, external and internal, voluntary and involuntary, were devitalised and toneless, and a flaccid condition of the uterine sac might well be put down to post-mortem relaxation and to be no sure evidence of the condition which held in the living subject. Frozen sections had been of enormous importance in advancing the knowledge of the anatomy of the pelvic and abdominal organs, but there were limitations to their value. As Dr. Barbour had said: "Great care is required in carrying over into clinical work the results gained from frozen sections. It is always a more or less cogent criticism that in them we are dealing with the dead, not the living, body—with anatomy rather than with physiology; with the machinery rather than with its movements." When a body was being frozen it was most likely placed on its back surrounded by a mass of ice and salt, in which it lay for days or it might be weeks. A certain amount of the freezing mixture was in contact with the skin. There was thus on the outside of the skin, which was a porous septum, a fluid with a high endosmotic equivalent, and inside the skin there was a fluid, like the liquor amnii, with a low endosmotic equivalent. A comparatively rapid flow of fluid from the body must pass into the salt solution, and by the end of the process one was not surprised that the sac of the uterus was flaccid and collapsed. Dr. Murray also referred to the direct evidence of the fact that the growing uterine wall was drawn tight over its contents—or, in other words, that there was a positive intra-uterine pressure—from the condition of the uterus at a Porro's operation, from the result of puncturing the membranes, from the experimental incision of the sac of a rabbit's uterus, and from the tension of the anterior uterine segment with tilting of the os uteri. Dr. Murray illustrated some of the points in the physics of the paper by different experiments on models.

Dr. BARBOUR agreed in opinion with much of the paper, differing only with regard to the question of amount of pressure. The simple question of the weight of the contents of the uterus had to enter into the physics of the matter. The tone of the abdominal walls varied in different patients and at different times of pregnancy; these abdominal walls formed part of the capsule surrounding the uterus and thus varying pressure was exerted on it. He considered that the evidence derived from frozen sections was not fallacious in a high degree, there being little difference in the facts obtained from them and those observed in life.

Dr. R. C. BUIST alluded to the fact that in labour there was a spherical bag of membranes even if no pain was present; the uterine walls in a state of tonic contraction must exert pressure on its contents.

Dr. J. W. BALLANTYNE stated that the evidence obtained from frozen sections was valuable so far as it supported clinical evidence. He differed from Dr. Murray in his opinion of the conditions under which the frozen sections were made. He always wrapped the body in mackintosh, and after some degree of freezing put it into a zinc case and surrounded it with the ice mixture; the results obtained could thus only be affected to a slight degree by the weight of ice or exosmosis.

Dr. HAULTAIN, Dr. ARMOUR, Dr. HAIG FERGUSON, Dr. FORDYCE, and Dr. MCVAIL joined in the discussion.

Dr. MILNE MURRAY, in reply, stated that the results obtained by the study of frozen sections did not determine the small points of physics in the living body. He also alluded to the experiments on the horn of the pregnant uterus in rabbits, which on puncture showed a positive pressure of 1½ in., and to the fact that if the uterine wall happened to be incised over the site of the placenta this would protrude through the wound.

GLASGOW MEDICO-CHIRURGICAL SOCIETY.

General Paralysis of the Insane.—Paralysis of the External Rectus Muscle.—Treatment of Diphtheria by Antitoxin.

A MEETING of this society was held on Feb. 19th, Professor MCCALL ANDERSON being in the chair.

Dr. R. D. HOTCHKIS read notes of a case of General Paralysis of the Insane, and showed microscopic sections of the brain tissue. The patient, a young man aged twenty-five years, manifested at the outset of his illness expansive ideas and delusions, but soon after admission to the asylum he improved so much that this diagnosis was departed from. He gained two stones in weight, and though distinctly weak-minded and unable to follow a continuous train of thought he was free from the mental and paralytic phenomena characteristic of general paralysis. In this condition he remained for ten months and the diagnosis was that of mild dementia. Then he suddenly broke down, general restlessness rapidly passing into acute mania developed, with refusal to take food and general degradation of habits, which continued for six weeks and terminated in exhaustion. There were no congestive attacks and no paralysis, and he recognised his friends twelve hours before death. The post-mortem examination showed the distinctive changes of general paralysis.

Dr. LESLIE BUCHANAN related a case of a woman, aged thirty years, in whom Paralysis of the External Rectus Muscle

Hosted by Google

of the right eye developed without manifest cause and after persisting some weeks gradually disappeared. Shortly after this an identical experience occurred on the left side. There was no history of syphilis, rheumatism, or hysteria, and the patient has remained quite well and free from all evidence of nervous disease for a period of two years. It was argued that time had established a strong presumption against any organic disease of the central nervous system and that under the circumstances the recurring paralysis must be regarded as a hysterical or functional condition.—Dr. MAITLAND RAMSAY, in discussing the case, insisted upon the importance of recognising paralysis of any of the ocular muscles as frequently an early event in the evolution of structural disease in the central nervous system. The very fact that the paralysis is transitory makes its significance in this respect all the greater.—Professor MCCALL ANDERSON expressed his substantial agreement with this statement.

Dr. WALKER DOWNIE read a paper on the Conditions necessary for Success in the Treatment of Diphtheria by Antitoxin. He discussed these under four heads—viz.: (1) the use of fresh serum, (2) early administration, (3) full dosage, and (4) repetition of the dose as required. Time was often lost in waiting for the result of a bacteriological examination, and similarly the use of too small a dose frequently led to failure. He used 5 c.c. of serum as a first dose or double that quantity if there were evidences of marked toxæmia or of laryngeal obstruction. Dr. Downie also showed the Tonsils removed in consequence of obstinate Mycosis Tonsillaris and exhibited microscopic sections illustrating the keratosis of the tonsillar epithelium.

Reviews and Notices of Books.

Deformities: a Treatise on Orthopædic Surgery, intended for Practitioners and advanced Students. By A. H. TUBBY, M.S. Lond., F.R.C.S. Eng., Assistant Surgeon to, and in charge of the Orthopædic Department, Westminster Hospital; Surgeon to the National Orthopædic Hospital; Surgeon to Out-patients, Evelina Hospital for Sick Children, &c. Illustrated with 15 Plates and 302 Figures. 1896. London: Macmillan and Co. Pp. xxii. and 598. Price 17*s.*

ALTHOUGH it may be urged with a great deal of reason that there is no really natural bond uniting the morbid conditions which are classed as Deformities, yet custom and practical convenience amply justify the practice, and, indeed, several other lesions, such as tuberculous diseases of the bones and joints, might with propriety be included under the same name.

It is only within the last forty or fifty years that the practice of orthopædics has been established on a satisfactory scientific basis, and towards the progress which has been made of recent years all civilised countries have contributed. We are glad to see that Mr. Tubby takes adequate recognition of the very great work in orthopædics which has been done by American surgeons. In fact, it is hardly too much to say that the most striking advances which have been made lately in this department of surgery have emanated from the other side of the Atlantic.

In a volume containing almost 600 pages there is obviously a great deal of scope for controversial statement, but we have found surprisingly little with which we cannot agree. The descriptions are clear and are greatly assisted by the very numerous illustrations that accompany the text; these amount to more than 300 in all, and though of somewhat unequal merit they nearly always demonstrate very clearly the conditions they are intended to portray. The portion of the volume which is on the whole most distinctively the author's is the account which he gives of his work on the reparative processes which take place in tendons after tenotomy. The classical observations of Adams will always remain very valuable, but microscopic methods have in many ways so improved that the questions were well deserving of re-examination. Mr. Tubby has made an extensive series of experiments on the tendo Achillis in rabbits. Tenotomy was performed and the results were carefully examined after various intervals from three days to thirteen months. The conclusions at which he arrived may be summed up as follows:—First, the new tissue is formed by plasma cells, derived in part from the connective tissue spaces of the tendon and in part from the dilated vessels of the inflamed tendon-sheath; secondly, the leucocytes play only a subordinate part, merely forming a pabulum for the development of the plasma cells; thirdly, for rapid union and for subsequent smooth working of the regenerated tendon it is essential that the tendon-sheath be interfered with as little as possible; and fourthly, that tendon is not capable of perfect regeneration after division.

The section devoted to talipes is very complete and occupies over 180 pages. We concur with the author in the preference he expresses for the open operation for section of the sterno-mastoid for torticollis as opposed to subcutaneous tenotomy; with modern asepsis there is practically no increased risk of infection, and the diminution of danger of wounding important structures is very great. Coxa vara has an interesting chapter devoted to it, with some excellent reproductions of photographs. In the prophylaxis of lateral curvature Mr. Tubby insists that great care should be taken to adopt the seat and desk to the child who has to use them, and he points out that a foot-rest is of great importance. Failure in attending to this point, especially in music-stools, is undoubtedly responsible for no small number of the cases of scoliosis, for in all cases where the feet have no resting-place very awkward attitudes have to be adopted merely for the purpose of maintaining the balance. There are a few points to which we are inclined to take exception, but it must be acknowledged that they are all unimportant. On page 19 Petit's triangle is described as being bounded posteriorly by the outer edge of the erector spinæ instead of by the anterior border of the latissimus dorsi. The spelling "rhachitis" cannot be supported by any etymological argument, as the word certainly does not mean "inflammation of the spine." The word was really formed by conferring a pseudo-classical appearance on the English word rickets. In comparing the supra-trochanteric osteotomy (Adams's operation) with the infra-trochanteric method (Gant's operation) the author is inclined to prefer the former, as he considers that by the latter operation a "very ugly angle" is likely to be left, and that non-union is apt to follow. We are inclined to think that these objections are theoretical rather than deduced from the results of operations.

Notes of a hundred cases are given, coming for the most part from Mr. Tubby's own case-books; they add greatly to the interest of the work. A copious index completes the volume. After a careful consideration of this book we feel justified in expressing the opinion that it is one of the most satisfactory and useful works on orthopædics in the English language. The paper and printing are excellent.

Aristotle on Youth and Old Age, Life and Death, and Respiration. Translated, with Introduction and Notes, by W. OGLE, M.A., M.D. Oxon., F.R.C.P. Lond., sometime Fellow of Corpus Christi College, Oxford. Longmans, Green, and Co., London, New York, and Bombay. 1897. Pp. 135.

THE literary members of the medical profession owe a debt of gratitude to Dr. Ogle for his admirable translation of these three little-known tracts of Aristotle as being the thoughts and ideas of a scientific philosopher who, though inaccurate in many ways, yet dominated physiological thought for many centuries after his death. The translation is prefaced by an introduction of some sixty pages wherein Dr. Ogle gives a scholarly and most interesting account of

Hosted by Google

the general doctrine in physiology held by Aristotle himself, his predecessors and successors, practically down to the end of the eighteenth century. "Life," says Dr. Ogle, "is ascribed by Aristotle to the presence of a soul of whose activity it is the manifestation. There is a soul in all living things ..... not itself corporeal, but yet inseparable from the body." The word translated soul is ψυχὴ, and must be carefully distinguished from the other word also translated in many instances soul—namely, πνεῦμα. The first word ψυχὴ means the principle of life, and exists in every animal, including plants; the second word πνεῦμα is applied only to humanity, and, perhaps, would be always better translated spirit, which would avoid confusion. This soul was considered by Aristotle to have its seat in the heart, and heat or fire was the necessary agent of its existence, being "the material substratum in which the soul was incorporate and without which it could not exist." This fire had to be fed by some fuel, and this fuel was supplied by the food. But excess of heat is as fatal to life as loss of heat, and so some provision had to be found for keeping it within bounds. This provision Aristotle finds in respiration for such animals as have lungs and for other animals in the bathing of their gills or the general surface of the body in a medium colder than themselves. He is thus brought to deal with respiration, and to this he devotes the chief part of his treatise. Shortly, his theory of respiration is as follows. Excess of heat will put a fire out, for if the air be excluded from the embers in a chafing-dish the fire will go out because the air tempers the excess of heat, so that if this tempering be removed the fire is extinguished by its own excess. Dr. Ogle quotes as an illustration of this theory remaining to the present time the popular idea that the sun shining on a fire will put it out. Perhaps a still more striking illustration of the notion that refrigeration was necessary for perfect combustion will be found in the controversy which raged in the early years of this century about the relatives merits of the hot and cold blast in the Scotch iron works. When James Neilson, about 1825, was trying to introduce his new invention of the hot blast he met with the strongest opposition from the iron masters. They argued, with perfect truth, that the furnaces worked much better in winter than in summer, but when they proceeded to find reasons for this fact they went hopelessly astray. Of course, they said, it is colder in winter than in the summer, therefore the colder the air the better the furnace will work; so, arguing on this wholly erroneous theory, they proceeded at great expense to devise means for cooling the air before blowing it in.

To return to Aristotle. The heart was constantly getting hot and had to be cooled; by getting hot it expanded the lungs; when these expanded in rushed the cold air and by cooling the central heat kept it within due bounds. This idea lasted until the middle of the seventeenth century and was upset by Boyle and Haller, the former showing that an animal confined with a limited supply of air died even though this air was kept quite cold, and the latter demonstrating that an animal could live in air at a much higher temperature than that of its own blood.[1] Altogether, the book is a most interesting summary of the various steps by which our present views on the great principles of physiology have been reached, and Dr. Ogle is to be warmly congratulated on the clearness with which he has set them forth.

LIBRARY TABLE.

Sir James Y. Simpson. By EVE BLANTYRE SIMPSON. Famous Scots Series. Edinburgh and London: Oliphant, Anderson, and Ferrier. Post 8vo, pp. 160, price 1*s.* 6*d.*—This is a very interesting and well-written little book, and we congratulate the writer on the way in which she has avoided the pitfalls she mentions in her preface. It is scarcely possible, indeed, to say too much in praise of a man such as Simpson, but it would be easy to cavil at that praise as set forth by a daughter, who naturally starts with a bias in favour of the object of her laudation. There is nothing though in this book that might not have been written by anyone conversant with Simpson's life and work. The book opens with a charming account of Simpson's parentage and childhood. They were passed in a very humble sphere, for his father was the village baker in Bathgate, Linlithgowshire. He lost his mother when only nine years old, and his only sister took her place. His up-bringing was in many ways scarcely such as the modern scientific worker would approve of; many old customs still held sway in the country side. For instance, when a murrain was devastating the cattle his grandfather had buried a cow alive as a sacrifice to the devil, and on buying a new farm a small piece of ground—needless to say, the most unproductive-looking portion—was carefully walled off for the use of the same individual. To pass on. When fourteen years old Simpson entered as a student at Edinburgh University, winning a bursary of £10 per annum. We have not space here to record all his struggles and trials, fought against and overcome with the indomitable perseverance characteristic of his race, for those our readers must search the book itself. Simpson's work is known to all the world, but his personal attraction is not so known. We may quote the following passage, which shows the manner of man he was (pp. 151–2). The incident occurred while he was on a journey. "One bitter winter's morning the train came to a standstill, when snow blocked the way, and while all the passengers, chilled, cross, and hungry, fumed, Sir James, in a long seal-skin surtout a grateful patient had given him, walked up and down to warm himself, for, notwithstanding all his furs, he was cold. He found a third-class carriage of shivering, starved children crying with misery. He got the station master coaxed into making some tea, piled his rug and newspapers upon the little ones, incited others to help, inspired all into more hopeful views of life, till the fire of his presence thawed them into geniality, and when the delayed train reached Edinburgh it was commented on as being the first which had arrived that day not filled with enraged and grumbling passengers. 'It's all that man,' said the guard, pointing to Sir James, who was hurrying off. 'It's a mercy we a' like him and coont it a pleasure to aye find his belongings, or he'd never own a rug or a portmanteau.'" The end of a very noble life came quietly on May 6th, 1870, and he was buried in the new cemetery at Warriston, although a last resting place was offered in Westminster Abbey. We can recommend to our readers this little book, for it is full of interest and charm. There is an interesting specimen of old chemical nomenclature which occurs on pp. 57 and 61, where chloroform is called "*per*chloride of formyl."

A Guide to the Examination in Practical Chemistry for the Conjoint Board. By P. A. E. RICHARDS, F.I.C., F.C.S., Demonstrator of Chemistry and Public Health at the Charing-cross Hospital Medical School, Public Analyst to the parish of St. Martin-in-the-Fields. London: Baillière, Tindall, and Cox. 1896.—We entertain as a rule a strong objection to books dealing only with the synopsis of a given examination, but in this case we may modify that opinion, inasmuch as in the first and third parts of this little work we find a well-prepared and accurate system of procedure laid down for the guidance of the student in detecting simple salts, and in making ordinary chemical preparations. No practical value, except for passing the examination, can be attributed to the three or four pages dealing with

[1] Vide Introduction, p. 51.

Hosted by Google

organic analysis; but this is of course due to the fact that a few substances only have been included in the synopsis by the authorities who direct the examination at the Board. It seems to us that it would be far better, if any real knowledge of practical organic chemistry were required, that it should be fairly stated, and not limited to odds and ends, such as urea and sugar, oxalates, &c., the composition and properties of which must be studied in practical medicine and physiological chemistry and might well be omitted from this part of the course unless it is taught in some well-defined relation to chemical science. The book is certainly an able guide to the examination.

The Private Sanatoria for Consumptives. By Dr. ARTHUR VON JARUNTOWSKY of Posen. Translated by E. CLIFFORD BEALE, M.A., M.B. Cantab., F.R.C.P. Lond., Physician to the City of London Hospital for Diseases of the Chest, &c. The Rebman Publishing Company. Price 1*s.* 6*d.*—Dr. Beale has done a most useful piece of work by translating this pamphlet. It gives in 46 clearly printed pages the essence of the means used in some of the best-known sanatoria abroad for the treatment of phthisical patients. The value of such sanatoria is only just beginning to be fairly recognised in this country, and the possibilities of the successful development of similar institutions here are, with few exceptions, not recognised at all. In spite of the small size of the book it is full of facts of much usefulness.

Water and Its Purification. By SAMUEL RIDEAL, D.Sc. Lond. London: Crosby Lockwood and Son. 1897.—Dr. Rideal has written this compact volume at an opportune time. There are very few handbooks on this important subject that deal with the various phases of the question right up to the present time, and yet no question has received greater attention and discussion of late than that in connexion with the purity of water supplies. Despite its conveniently small size the book covers the whole ground of recent developments even as far as the now admitted worthlessness of the majority of domestic filters and the value of Dibdin's method of examining with minute exactness the insoluble matter in water, the recent application of which led a few months ago to an unfavourable opinion on the quality of the London supply and the function of the companies' filtering beds. The work is written with singular clearness and freedom from technicalities, the practical side of the question being treated with the same consideration as the theoretical side, including those questions affecting the methods of analysis for determining the fitness of waters for drinking purposes. The last chapter on the Analysis and Interpretation of Results is especially good, summing up the value of both bacteriological and chemical analysis without prejudice for or against the respective merits of these two methods. As a work dealing as clearly as it does with the various ramifications of such an important subject as water and its purification it may be warmly recommended. Local authorities and all those engaged in sanitary affairs, and others interested in water-supply, will read its pages with profit. We have noticed but one slip, and that is in connexion with the quality of Loch Katrine water. It has not, as is stated on page 117, any objectionable action upon lead, and no cases of lead poisoning have ever been traced to the drinking of this water, despite its great purity and softness. Curiously enough the author says as much some pages further on (137).

The Progress of Medical Chemistry. By J. L. W. THUDICHUM, M.D. Giessen, F.R.C.P. Lond. London: Baillière, Tindall, and Cox. 1896. Price 5*s.*—No more forcible argument in favour of the medical student possessing a sound knowledge of chemistry, and more especially of that portion of the subject bearing directly on physiology, pathology, and medical practice, could be advanced than that which is contained in the interesting chapters of the volume before us. The contribution appeals as plainly as anything can appeal for a closer study of and attention to the interesting and very important field of medical chemistry. As might be expected, the bulk of the work is devoted to the chemistry of the urine, but in Chapter xiii. (there are in all seventeen chapters) we come to the discussion of the chemical composition of the brain. This subject has been fiercely debated, and Dr. Thudichum, in recounting the history of the subject, makes some severe remarks upon the methods of the partisans of the protagon hypothesis. This is followed by a chapter on the new organo-therapy. Finally, there is a chapter on "A Shady Side of Biological Literature," in which the author, in a somewhat edifying way, refers to the "blunderings" and "forgeries" which he states characterised certain published results of research. Here also he animadverts on "cooked researches," which he defines as "compounds in which known data are skilfully blended with more or less new matter in such a manner as to make the whole appear as new," and upon "'trimmed researches' which are mostly new data of an inferior kind to which an appearance of greater precision is given by clipping or adding particularly to analytical figures to make them fall in with pre-conceived hypothesis," and so on. It is to be feared that Dr. Thudichum is in many cases correct in what he says in regard to this matter, and he supports it by citing some apparently notorious cases. We welcome the publication of investigations which belong to this really important section of medical science, and of published contributions of this sort there is not an abundance.

Handbook for the Bio-chemical Laboratory. By JOHN A. MANDEL, Professor of Chemistry at the New York College of Veterinary Surgeons. London: Chapman and Hall, Limited. 1896. Price 6*s.* 6*d.*—This is essentially a book for the laboratory bench, containing a description of the methods of preparation of physiological substances, while at the end of the volume will be found numerous tests for various pathological products arranged alphabetically. A book of reference of this kind has long been wanted, as hitherto the laboratory student was compelled to refer to more or less big and bulky works on physiology, in which the practical information and direction of testing he required to know are more or less scattered through the pages of the volumes. The present book facilitates this kind of reference and affords at once that requisite information concerning the processes of preparation of such important bodies as glycogen, inosite, fibrin, nuclein, ptyälin, protagon, urea, and many other physiological products. Those who are engaged in this important branch of study will readily appreciate the value of such a convenient publication.

The Manufacture of Aërated Beverages, Cordials, &c. By W. STEVENSON and R. HOWELL. Fourth Edition, revised and enlarged. Published by the authors at 95A, Southwark-street, S.E. 1896. Price 5*s.*—Primarily, this is a book of receipts and contains also some useful and sound information on the points to be observed for the production of a satisfactory temperance beverage. The book is evidently appreciated by the trade, since it has reached its fourth edition, and much new and valuable matter has been added.

JOURNALS AND REVIEWS.

The Quarterly Journal of Microscopical Science. Edited by E. RAY LANKESTER, F.R.S., ADAM SEDGWICK, F.R.S., and W. F. R. WELDON, F.R.S. Vol. XXXIX, Part 4. January, 1897. London: J. and A. Churchill. Pp. 202. Price 10*s.*—The present part concludes the thirty-ninth volume of this journal. It contains two original and highly interesting articles, the first by Lily Hine, on the Changes in the Cell Organs of Drosera Rotundifolia produced by Feeding with Egg Albumin; the second by J. T. Wilson, Professor of Anatomy,

Hosted by Google

and J. P. Hill, Demonstrator of Biology in Sydney University, Sydney, New South Wales. The author of the first paper quotes some of the observations of Darwin, Cohn, De Vries, and Gardiner on the effects of feeding the drosera and then proceeds to give the results of her own observations, which were partly performed in Scotland and partly carried out in the physiological laboratory, Oxford. She gives the formulæ for various fixing fluids she has found serviceable and describes in detail the structure of the glands. Well-executed drawings are given which show the microscopical structure presented by unfed leaves and by leaves examined at various periods, varying from one minute to a week, after being fed. The article concludes by stating that an appropriate stimulation of the gland cells of drosera by food leads to the using up of the basophile cytoplasm, which is ultimately represented by a very scanty eosinophilous plasm. The restoration of the cytoplasm is brought about by the nucleus absorbing food material, metabolising it, and then excreting it into the cytoplasm. The reasons that have led her to this conclusion are then given. The article of Professor Wilson and Mr. Hill on the Development and Succession of the Teeth in Perameles, or the Bandicoot, one of the Marsupials, as well as in the Dasyurus, Phascogale, Trichosurus and Macropus. The dentition of these animals has always been held to possess special interest, the authors observe, as they have been considered likely to afford important clues to the phylogenesis of the teeth in mammalia generally. On examination, however, the subject is found to present many difficulties which have led to great differences in the interpretation of the phenomena of dentition in the marsupials generally. After giving in full detail and with continuous criticism the views of other observers, the authors state they are satisfied that the permanent teeth of marsupials are the homologues of the permanent teeth of higher mammals, that the deciduous premolar is a true milk tooth and is not the sole representative of the series to which it belongs, since the so-called prelacteal teeth are in reality milk teeth which have undergone reduction and have well-nigh wholly disappeared under the operation of influences unfavourable to their development; finally, the lingually situated down-growths of the dental lamina by the sides of the developing teeth are not rudimentary enamel germs, but are portions of a quite indifferent "residual dental lamina." The article is illustrated by several plates and many drawings.

The Journal of Physiology. Edited by MICHAEL FOSTER, M.D. Lond., F.R.S., and J. N. LANGLEY, Sc.D., F.R.S. Vol. xxi., No. 1. London: C. J. Clay and Sons. February, 1897. Price 5s.—The articles contained in this number are:—1. The Oscillations of the Auricular Tonus in the Batrachian Heart, with a Theory on the Function of Sarcoplasma in Muscular Tissue: by Dr. Phil. Bottazzi, of the Physiological Laboratory, Florence. This is an endeavour to explain, amongst other phenomena, the reason of the superposition of two contraction curves caused by two stimuli following each other within a short space of time. The author holds that it is due to the sarcoplasm, which, being in its phase of contraction when the second stimulus comes into action, "supports" the doubly refractive substance during the second contraction, which accordingly rises higher. The evidence for this theory is given at length. 2. The second article is by Mr. C. B. Davenport and Mr. W. B. Cannon of Harvard College, on the Determination of the Direction and Rate of Movement of Organisms by Light. The problem which the authors of this article have attempted to solve is whether the migration of organisms towards or from a source of light is to be accounted for by differences in intensity of light along the path taken or by the direction of the incoming rays, and they believe the latter view to be correct. 3. On Reciprocal Action in the Retina as Studied by Means of Some Rotating Discs, by Dr. C. S. Sherrington, F.R.S. This paper is illustrated by many ingenious modifications of Maxwell's discs. 4. Ingestion and Excretion of Iron in Health, by Dr. Ralph Stockman, and Dr. E. D. W. Greig. The authors show that the amount of iron ingested and egested is very small and can be very accurately determined. 5. On the Mode of Absorption of Fats, by Mr. B. Moon and Mr. D. P. Rockwood.

The Journal of State Medicine. Vol. V., No. 2. London: Baillière, Tindall, and Cox. Price 2*s.*—The recent experiments in sewage treatment at Exeter form the subject of the first paper in this number of the journal. These experiments by Mr. Donald Cameron, the city surveyor of Exeter, were treated in full in our columns on Dec. 5th, 1896, under the heading of "The Utilisation of Micro-organisms in the Purification of Sewage." Dr. A. Campbell Munro contributes a paper on the Inter-Notification of Infectious Diseases among Local Authorities, in which he discusses the system at present in force in and around Glasgow. Dr. Munro advocates the extension of the system to the whole of Scotland and suggests as possible centres Glasgow, Edinburgh, Dundee, and Inverness. He thinks that until some such system as he sketches is adopted full advantage will not be taken of compulsory notification. Mr. A. B. McDonald, C.E., the city engineer of Glasgow, contributes a paper on Formulæ relating to Capacity, Velocity, Flow, and Discharge of Sewers.

To the *Veterinary Journal and Annals of Comparative Pathology* for February Mr. R. Stewart MacDougall, M.A., B.Sc., contributes an interesting paper on the Bacteria of the Soil, based on the experiments of Professor Nobbe and Dr. Hilltner. This article contains most valuable information as to the conditions necessary for the absorption of nitrogen from the soil and from the atmosphere. Short articles on Gangrenous Dermatitis and Veterinary Education in America, Extracts from Foreign Journals, Notes and News, and reports of the various veterinary societies make up the number.

The Veterinarian for February keeps up the high standard that we are led to expect for the articles in its columns. The first original paper, by Dr. Carlier of the Physiological Laboratory of the University of Edinburgh, gives the commencement of a description of the Pancreas of the Hedgehog during Hibernation. This part of the paper is devoted almost entirely to methods of preparation and to a discussion of the nature of certain portions of the pancreatic cells, but the paper promises to be of high scientific value. Veterinary-Major F. Smith contributes the first part of an interesting account of the Symptoms and Lesions of Anthrax in the Horse. Mr. Dollar has translated Nocard's case of Ulcerating Lymphangitis simulating Glanders-Farcy in the Horse, which appeared in the *Annales de l'Institut Pasteur* towards the end of last year. The interesting points in this case are—(1) the multiplicity and rapidity of formation of the abscesses; (2) the rapid cicatrisation of unhealthy-looking wounds; and (3) the absence of lesions in the lymphatic glands, especially as it was clear that infection took place through the lymphatics. A number of clinical cases are also given. Perhaps the most striking feature in this month's *Veterinarian* is the number of good abstracts included under the Month's Progress. Then follow reviews; an interesting biographical sketch of the veterinary officers of the Board of Agriculture, Mr. Cope and Mr. Duguid, accompanied by exceedingly good photographs of these gentlemen; a pass-list of examinations; and full accounts of the meetings of various veterinary societies and of the Royal College of Veterinary Surgeons. The activity displayed amongst members of the veterinary profession and amongst those who have the conduct of the education of these members gives promise of much valuable work.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 27, 1897.

ON Friday, the 19th inst., there was a large gathering in the theatre of the United Service Institution to listen to a paper read by General R. L. DASHWOOD on the health of our troops in India and at other foreign stations. The paramount subject for consideration at the present time, however, is that affecting the British army in India. The reading of General DASHWOOD'S address was followed by an animated discussion, and the figures which formed the basis of it were sufficiently startling to arrest attention. Some of the speeches were good and pertinent, and among them Sir DONALD STEWART'S; some struck us as either wide of the mark or involving erroneous or doubtful assumptions. There is probably no civilised nation in which there exists a state of things similar to that which obtains with our army in India at the present time. The returns of Continental armies do not show anything approaching the amount of venereal disease that prevails among our troops in that country; and we can quite understand that the extent of the evil is a matter of grave consideration to those responsible for the military efficiency of the British force serving there. It is very important, however, seeing that figures and statistical data are so apt to be misleading to those who are little accustomed to deal with them, that we should not allow ourselves to be diverted from the main point at issue by statistical discussions about figures, ratios, and decimal points. We advert to this because of the confusion that apparently exists in the minds of some writers and speakers. To take an elementary point as an illustration. An admission-rate does not mean that each admission represents a separate and different individual, nor is the ratio of 500 admissions per 1000 per annum the equivalent of 500 men, or half of a regiment 1000 strong, because the same man may be admitted more than once during the year with the same disease, and with the class of disease under consideration this was most probably the case. The public requires to be told authoritatively the exact figures representing the amount of inefficiency caused by these diseases in the British Army in India. We are glad to learn, therefore, from Lord GEORGE HAMILTON, the Secretary of State for India, that a Departmental Committee had been appointed under the presidency of Lord ONSLOW, of which Sir JAMES PEILE, Member of the Council of India, Surgeon-Major-General TAYLOR of the Army Medical Staff, and Surgeon-Colonel J. RICHARDSON, a retired officer of the Indian Medical Service, are the members, to inquire into, and report upon, the actual state of the army in India in this respect. The report of that committee may be confidently expected shortly, if it has not already been published, and there will then be no longer any room for cavil or doubt on the subject.

But statistics cannot, after all, give any adequate measure of the extent of an evil of this nature. An individual contracts small-pox, scarlet fever, or other infectious fever; he lives or dies, and there is an end of it. He is legally compelled to remain isolated during the attack and if he recovers he returns to his family or occupation when he is no longer a source of danger to others. But with a syphilitic infection the case is far otherwise and far worse. No statement about the quantity, or even the severe or virulent quality, of the poison covers the subject; a constitutional taint has been acquired of the most chronic and insidious kind, from which the patient may never recover, and in many cases the sequels of the infection, from its initial stage to its remotest consequences, make up a terrible medical history; nor is the individual sufferer the only victim of the infection, for it may, and frequently does, involve the innocent and the unborn. These facts are so well known to the medical profession that the bare statement of them amounts to a platitude. We endeavour to limit the spread of infectious fevers on the grounds of public health and public policy. Why should we not, then, deal with this disease as we do with other infectious diseases, in which the reasons for doing so are less numerous and far less imperative? As regards the cruel results of our negligence in India in this respect and the virulent nature of the poison, Mr. H. W. WILSON, M.P., and others interested in the subject, may determine these for themselves by a visit to Netley.

But it may be said that the compulsory Lock Hospital system as it was tried in India proved an inadequate measure and failed to accomplish all, or anything like all, that was expected from it. Still, we have now had proof that it did exercise a repressive influence, especially in checking the increasing prevalence of this disease. Without going into the exact measure of this influence in figures, in order to avoid entering upon any contentious matter, this fact remains and cannot be gainsaid. But we agree in thinking that the mere return to the cantonment lock hospital system as it was worked in the past would be an inadequate way of dealing with the evil. We do not at all desire to discount or minimise the difficulties in the way of dealing with the subject, but as far as India is concerned it calls for serious and honest consideration. We are confronted, let it be remembered, with two questions—the safety of the empire and the welfare of future generations. What is required to be done now is just that which an intelligent exercise of common sense—and it may be added common justice to our short service army in India—would dictate, namely, to ask those best acquainted with all the present conditions of that country to formulate some scheme after due inquiry by which they would propose to deal with the subject as a whole. We are glad to notice that there is a growing desire on the part of people who are not faddists to give the Government of India a free hand in this matter. Among the number of officials and others in that country—men of the highest character and capacity with general and local, as well as military and medical, experience to guide them—it seems ridiculous to

Hosted by Google

suppose that there are none who can be relied on to suggest measures for dealing with a growing evil the gravity of which they all recognise.

ALTHOUGH Lord CROMER'S annual report on the finances, administration, and condition of Egypt is published this year somewhat earlier than usual, it nevertheless contains the usual amount of interesting matter, expressed in his customary forcible and concise language. As a diplomatist the British Consul-General admittedly occupies the first rank, but no one can find fault with the lucidity and straightforwardness of his declarations; and in the present case it is not too much to say that within the moderate compass of twenty-seven pages everything of importance connected with our protectorate is clearly and adequately dealt with. Finance, being the foundation of all administration, naturally comes first, but we can only give a hasty glance at this portion of the subject. The system of furnishing the accounts hitherto in force, being calculated to cause misapprehension as to the amount of money at the disposal of the Treasury authorities, has been amended, and in future only the actual sum which the Egyptian Government is at liberty to employ will be shown as surplus. This change is, however, merely one of form. "The substantial facts connected with the financial situation of the Egyptian Treasury remain unchanged." According to the estimates for last year the probable excess of revenue over expenditure was set down at £E17,000 only, but as a matter of fact on Dec. 31st the savings under this head were found to amount to £E316,000. This, of course, would have been a handsome balance out of a total of ten millions, but, unfortunately, it did not in reality exist. The Soudan expenditure had not been included in the accounts, and there were, "moreover, further liabilities, amounting in all to about £E500,000" which will have to be made good. Instead of holding an available cash surplus the Egyptian Treasury is consequently in debt to the extent of £E780,000. It is true on the other hand, that the Commissioners of the Caisse de la Dette are in possession of upwards of £5,700,000 sterling, this enormous accumulation being solely due to the reforms that have been instituted under English guidance; but, as Lord CROMER has often explained, the funds controlled under international arrangement are practically out of reach so far as local needs are concerned. With the finances of the country in this condition it is vain to hope for sanitary reform on anything like an adequate scale. The Consul-General's arguments in this connexion are, unfortunately, irrefutable. Commencing by quoting ROGERS Pasha that—"There is but one satisfactory way to safeguard a country against cholera, and that is to put it in such a sanitary condition that, even if introduced, the disease will not find a favourable soil for its development," Lord CROMER goes on to observe—"There can be no doubt of the truth of these remarks. It is, however, the misfortune of the sanitary reformer that the sums of money required to execute his very necessary reforms are large. ..... Amongst the objects which most nearly concern the general welfare of Egypt it cannot be doubted that the re-conquest of some portion, at all events, of the Soudan takes a very high place. It is to the accomplishment of this object that the attention of the Egyptian Government must, for the time being, be mainly directed. More than this, the development of the system of irrigation should not be long delayed, more especially as the returns to be obtained from money spent on irrigation will certainly in the end provide funds for expenditure in other directions. No Government, and certainly not the semi-internationalized Government of Egypt, can afford to embark at once and at the same moment in a number of expensive and difficult operations. I do not doubt that the day of the Egyptian sanitary reformer will come, but under the circumstances to which I alluded above, I fear, though I say it with regret, that some little while must yet elapse before the question of improved sanitation in Egypt can be taken seriously in hand."

Although it has been found necessary on financial grounds to allow the larger issues connected with the improved sanitation of the country, including the sewerage of Cairo and other large towns, to stand aside for the moment, it must not be supposed that all sanitary progress is in abeyance. On the contrary, several minor improvements of considerable importance have been made. Until a few years ago the mosque latrines were allowed to drain into the nearest water-supply, but in 1892 a law was passed under which power was conferred on the Minister of the Interior to close all establishments of this description which were pronounced to be dangerous to public health. The number of mosques dealt with last year in virtue of this law was 167. Again, in January, 1894, a long-considered law was passed allowing the sanitary authorities to cause the transfer of cemeteries whenever the adoption of such a measure was deemed necessary for the public weal. In 1896 the number so transferred was 179. Needless to add that these reforms are of primary importance from a hygienic point of view, and although they both deal with subjects upon which Mahommedan opinion is naturally somewhat sensitive, it is extremely satisfactory to find them progressing steadily without exciting the slightest ill-will or opposition on the part of the population. In addition to the foregoing another highly important sanitary innovation is mentioned by Lord CROMER. In 1895 water of apparently good quality was found near Tantah at about seventy-five feet below the surface. This water has now been pronounced by a competent authority to be of the best possible quality for human consumption, being entirely free from bacteria of any kind. A well is consequently being sunk for the supply of the town, and it is hoped that the pumps will be erected, and the pipes for distribution laid, during the course of the ensuing summer. It is impossible to exaggerate the importance of this new departure, for no hygienic boon can surpass a pure and plentiful water-supply. Experiments regarding the subsoil water are also to be undertaken at Zagazig, as well as in several other towns, both of Upper and Lower Egypt. With regard to new constructions Lord CROMER informs us that during the year one hospital, five disinfecting stations, five slaughter-houses and a hygienic institute were erected. The alterations at the Kasr-el-Aini Hospital at Cairo are also approaching completion and will probably be finished next March. The total cost of this work is £E22,000, of which £E5800 were

Hosted by Google

expended in 1896. Further, we find that ten new dispensaries have been opened in the provinces and that up to the end of October 292,000 persons were successfully vaccinated, the lymph for 40,000 of them being obtained from the local vaccine institute.

On the whole Lord CROMER'S record indicates anything but hygienic stagnation and Egyptian sanitarians have no cause to be downhearted. Everything comes to the man who knows how to wait. The chief authority in the land is fully impressed with the importance of sanitary reform, and as soon as the requisite money is available it will doubtless be freely accorded.

LAST week ought not to be without its influence in the history of vaccination; indeed, it might not inaptly be termed "Vaccination week." On Feb. 16th an able paper by Mr. NOEL HUMPHREYS was read at the Royal Statistical Society on English Vaccination and Small-pox Statistics, and on Feb. 19th there was read at the Epidemiological Society a most exhaustive paper dealing with the Dissentients' Statements in the Report of the Royal Commission on Vaccination. The writer of this paper was Dr. MCVAIL, whose knowledge of, and methods of handling, small-pox questions are unsurpassed, and we should like to see a copy of this crushing reply to the anti-vaccinationists placed in the hands of every Member of Parliament and every public vaccinator. On the same day, too—but at an earlier hour—a discussion took place at the Society of Medical Officers of Health upon the paper which Dr. BOND of Gloucester recently read. These discussions should end in some practical good and in recommendations which will strengthen the hands of our legislators in guarding this country against the ravages of epidemic small-pox. Mr. HUMPHREYS has clearly but little respect for the recommendations of the Royal Commissioners, "who conclude a report teeming with evidence as to the value of vaccination by recommending a course of action which would practically make the compulsory clauses a dead letter without repealing them." He obviously sees that it is to re-vaccination we must look if there is to be any relaxation whatever as to primary vaccination in this country. The Epidemiological Society are evidently of a similar way of thinking, and they have passed a resolution which will, we imagine, be presented to Parliament, strongly advocating that if the recommendations of the Commission as to primary vaccination be adopted re-vaccination should be placed on practically the same footing. We expect, too, that the Society of Medical Officers of Health will have little doubt as to the necessity for advising re-vaccination. If the two societies here referred to are practically unanimous in their opinion as to re-vaccination the legislature will be incurring a very grave responsibility should it disregard such an expression.

At the present crisis—for it is a crisis—there is one object that the medical profession must keep steadily in view, and that is re-vaccination. If, as seems not unlikely, the recommendations of the Commission with regard to primary vaccination become law, and owing to postponements and general laxity there grows up all over the country, instead of, as at present, in a few centres only, a mass of unprotected infants, it is very necessary that some compensating influence should be at once introduced, and that influence must be re-vaccination carried out through the agency of our educational system. Re-vaccination is necessary to protect the public against small-pox, and it is the only course which will carry conviction to the minds of the less educated electorate. The masses who are influenced by such anti-vaccination clap-trap as was heard last week from Mr. MILNES at the Royal Statistical Society are unable to discriminate between vaccination and re-vaccination, and the arguments of the anti-vaccinationists obtain an easy ascendancy. So long as a large number of vaccinated persons are found in our small-pox hospitals, so long will the ignorant masses refuse to believe in the efficacy of vaccination, as illustrated by primary vaccination; but when by the use of re-vaccination at, say, ten years of age we prevent the primarily vaccinated from becoming inmates of our hospitals we shall then have furnished an argument which will be clearly understood by the people. If we fail to insist upon practically universal re-vaccination, while still allowing the conscience clause of the Commissioners to be operative, we shall, in spite of all our efforts as to isolation, bring primary vaccination more and more into discredit until the people who govern this country will be so discontented with it as to insist upon the complete removal of even the machinery of vaccination. The agitators who have led the anti-vaccination campaign are men of energy, of ability, and above all, of ambition, and they will continue their work. Let not, therefore, the medical profession be led away by any red herring of "sanitation," whether as an adjunct to, or a substitute for, re-vaccination. The anti-vaccinationists are but too anxious to lead us away on this scent, as was clearly evident at the debate on Feb. 16th on Mr. HUMPHREYS' paper. The point at issue now is the value of *re-vaccination*, and it is to be hoped that the medical profession will recognise and avoid the false trails laid by the anti-vaccinationists and their friends. Let us extend isolation accommodation by every means in our power, but let us at once limit its requirements within the bounds of practicability by a well-considered system of re-vaccination. No one who is familiar with the difficulties of sanitary administration can believe for one moment that isolation accommodation for small-pox alone can ever be provided in advance or at the time of an outbreak sufficient to cope with small-pox of the type which prevailed at Gloucester. It is this variation in type and infectivity which is the keynote to this question of isolation. At Leicester the type was mild and apparently not of a high order of infectivity, but even there, with the much-vaunted sanitary organisation and the defective hospital accommodation of that town, there was much chaos. The hospital apparently spread the disease, in spite of the fact that the town council pretended to have a perfect sanitary organisation. If the suggestions of the Commission that vaccination be performed indiscriminately by all medical men, and that the age of moderate compulsion be postponed is acted upon, we shall have a large number of children imperfectly protected with but one small mark. This it appears to us is inevitable, and we believe it would be the conscientious opinion of the vast majority of public vaccinators and vaccination officers throughout the country. Under these

Hosted by Google

circumstances there is but one effective course open, and that is to compensate for indifferent primary vaccination by a system of re-vaccination of children before they cease attending the elementary schools.

We are fully aware that the political and social exigencies of the situation must decide exactly what form legislation should take, but it is nevertheless the serious moral duty of the medical profession to state plainly and with no uncertain voice what is necessary to control small-pox and to prevent it from steadily reverting to what it was before the days of JENNER.

Annotations.

"Ne quid nimis."

THE NINTH INTERNATIONAL CONGRESS OF HYGIENE.

IT will be remembered that the Eighth International Congress of Hygiene and Demography, which met at Budapest in 1894, accepted the invitation of the Spanish delegation to hold the next Congress at Madrid in 1897. We regret to state, however, that it is almost certain that this Congress will be postponed. The most ardent partisans and efficient organisers of these congresses are undoubtedly the French sanitary reformers and notably the members of the Society of Public Medicine and Professional Hygiene. This society has consequently become a sort of international link between various organisations of sanitary reformers in different countries. The organisers of the Spanish Congress have therefore communicated with the French Society of Professional Hygiene and at first suggested that the Congress should be held this autumn. The date chosen clashed, however, with the period of the medical examinations held in France. As the students who obtain their diplomas are exempted from full military service the examinations take place earlier than was formerly the case, so that the candidates may know the result before the usual time for joining their regiments. Were the Congress to be held at the date first mentioned none of the French medical men engaged on the examination boards could attend. Many of the most distinguished and prominent French delegates would have to be absent. This difficulty was explained to the Spanish organisers, and they were requested, if possible, to alter the date. Their reply went a good deal further than the altering of the date, for they pointed out that Spain was at the present moment suffering terribly from the strain caused by two great colonial wars. At the same time, the Spanish press alluded to the Congress in very doubtful terms, and it seemed as if, at least for the moment, the task of holding the Congress was beyond the power and capacity of its organisers. There was also this difficulty, that the climate of Madrid is too hot in summer and far from agreeable in winter. The choice of suitable seasons is limited to the spring and late autumn. In the face of these hesitations and difficulties the French have proposed to their Spanish colleagues that the Congress should be postponed till Easter next year. At no time of the year is Spain so pleasant and so interesting as at Easter, and to postpone the Congress till that date would involve a delay of not more than about six months. To this it may be objected that, though Spain is near to France, it is far removed from most other countries, and as the Easter holidays are of short duration many delegates of the more distant nationalities may not have time to go so far. Then, again, it is unfortunately not at all certain that the political situation in Spain will have very materially improved by Easter, 1898. In that event, there is reason to fear that the Congress may collapse altogether. Luckily, we may take it as certain that though no vote has been given, no invitation issued, and no opinion expressed save in private conversations, the Congress will meet in Paris during the Universal Exhibition of 1900. A great European war alone would prevent this happy consummation. At the same time this would imply a lapse of six years between the holding of the seventh and eighth congresses, and such a delay cannot be viewed as otherwise than most injurious to the cause of international sanitary progress. It confirms once again the opinion we energetically expressed during the International Congresses of Hygiene held in London in 1891 and in Budapest in 1894. We then maintained that the congresses had become utterly unmanageable. It was possible to control the earlier congresses. Some 500 delegates, representing about twenty nationalities, can be suitably entertained and their discussions brought to a practical issue. Now, however, that these congresses are attended by something like 3000 delegates, the number of towns in Europe that possess adequate halls or assembly rooms and sufficient wealth and accommodation to receive hospitably and with credit to themselves so vast a gathering is very limited. It will not be surprising if, in their present distress, our Spanish colleagues find the task beyond their strength. But it is precisely in such countries as Spain, where sanitary reform has not made much progress, that the leading hygienists of the world should gather together and, by their presence, stimulate the movement. This, however, can only be done when alterations have been introduced in the management of the congresses which will reduce the expense and the number of delegates.

ITALY AND THE PLAGUE.

OUR Romec orrespondent writes:—Touched at many points by Indian traffic—abounding in *entrepôts* of travel between the great British dependency and Europe—Italy is, more than any other Continental Power, exposed to the risk of contagion from the pestis bubonica; but what is she doing in self-defence? Holding meetings of her Consiglio Superiore di Sanità; giving hospitality to the International Conference at Venice; issuing orders for the prohibition of suspected ships from her ports; and little or nothing more. Compare her inaction or inertia with the conduct of France, which is much less exposed to the danger, and what do we find? At the Pasteur Institute in Paris there are already 100 horses "immunised" and capable of furnishing the "serum anti-pestiferum" in ample quantity Italy, on the other hand, has no such precautionary energy to show. Not that her medical men are idle in the matter. They are constantly appealing to the Government to initiate the French example and enlightening the public as to the safeguard it may possess in presence of the danger. But, as usual, the profession in Italy is far ahead of the administrative or municipal authorities, and has to gain the ear of one or other only by informing the public and raising the *vox populi* for sound hygiene. Italian medical schools number no more able pathologist and sanitarian than Dr. Guido Banti, Professor of Pathological Anatomy in the "Istituto di Studi Superiori" of Florence, and in a communication addressed not so much *ad clerum* as *ad populum* he puts the country in possession of facts to which the State cannot long be indifferent. Sero-therapy, he maintains, can cope successfully with the plague if properly and opportunely applied; nor is the "serum anti-pestiferum" difficult to be had. Inject under the skin of a horse a certain quantity of pestiferous culture and at the point of inoculation the tissues get presently inflamed. For some days the animal is in fever, but this having run its course it gets well again. Repeat the injection with a greate

Hosted by Google

quantity of the culture and the same phenomena are presented once more. Still repeating it, we find the blood of the animal has acquired special properties. It is bled and the blood is allowed to coagulate in vessels, separating into two parts the red coagulum and a liquid, transparent and yellowish, which is the serum wanted. This is a veritable antitoxin for the plague. Inoculate a few milligrammes of it in a rat and then infect the animal with the "cultura pestifera." Its health is unimpaired. Infect with the same culture another rat which previously has not been treated with the serum and it dies invariably. Take a rat already suffering from the plague and inoculate it with the serum and it almost invariably recovers. Such, briefly stated, is the practice of Yersin, who in twenty-six subjects ill from the plague has achieved by it twenty-four cures—the two who died having been treated too late. In a disease which numbers 90 per cent. of fatalities the Yersin practice is, indeed, a boon which Professor Banti and his brethren do well to bring before the lay public with a view to its being pressed upon the State. Thanks to the same enlightened action of the profession the public are taking a less superstitious view of sanitary cordons and such protective measures. In the recent epidemics of cholera, says Professor Banti, those measures were useless if not positively harmful. But plague is different from cholera, as in this connexion he proceeds to show. In 1815 it appeared at Noia in the Abbruzzi, and a military cordon was at once drawn around the city and rigorously maintained. "Il male si spense ove era nato" (The disease was extinguished where it was born). Again, in 1878-79 the plague ravaged the provinces of Astrakhan in Russia, and again the same measures, severely enforced, circumscribed and choked it. Why so? Because, replies Professor Banti, the bacilli of plague are extremely delicate bacteria, dying easily and easily losing their virulence, not holding out against desiccation—in a word, "they are micro-organisms even more fragile than the vibrios of cholera." Rigidly practised, therefore, such measures can protect the country from the intrusion of plague. Again, even if it has effected an entrance, Italy (though in a less degree than France) is not the Italy of "sixty years since"; she has shared in the modern movement of hygiene, public and personal, and is *pro tanto* protected against a malady which, under insanitary conditions, reaps its thousands. For plague propagates itself neither through the air nor the water and the bacteria which produce it are easily destructible—they can, for instance, be prevented from contaminating the soil, that indispensable condition for the development of plague. A truce, then, to the fumigations, inspired by panic, at frontier stations. Suspected cases, at once isolated, but not in "lazzaretti," and subjected for a few days to medical surveillance, are excluded from all possibility of diffusing the contagion; and if the malady declares itself in its true colours there is always the "serum anti-pestiferum" to combat it. But no time must be lost by the State in providing the protective measures, on the one hand, and the antitoxin, in sufficient quantity, on the other. It has had ample warning from medical authority already. All the greater must be its responsibility if, in the light of such warning, it adheres to its favourite maxim, "inertia sapientia," from which Italy has suffered so heavily in the past.

CORONER AND MEDICAL MAN.

IN THE LANCET of Feb. 20th we had occasion to comment upon a regrettable incident that occurred at an inquest, and from the reports before us we considered that the action of the medical man was consistent with both the spirit and the letter of the law. It is now our duty to draw attention to a conflict between a coroner and medical man in which other issues were raised. An inquest was recently held at Grays by the deputy coroner touching the death of an infant aged five months. Deceased had suffered from "discharge from the head during the few days previous to its death." On Feb. 5th the child was left in bed by the mother apparently asleep. The bedclothes were clear of the face. Shortly afterwards it was noticed that something was wrong and Dr. Snell was sent for, but before his arrival the child was dead. The report of the inquest relates that Dr. Snell stated in his evidence that "he had not the slightest information as to whether the child died a natural death or the reverse; and at the request of the father he made a post-mortem examination and found the cause of death to be asphyxia." When asked the cause of death Dr. Snell refused to answer on the ground that the coroner had not issued an order for a post-mortem examination, and that he should not divulge the secrets obtained by a necropsy privately paid for by the parents. That an inquest was necessary in this case there can be no doubt. That a necropsy was desirable seems probable, but upon the coroner was cast the duty to determine these points. We have frequently asserted that where the cause of death cannot be determined beyond reasonable doubt from the general and medical evidence a post-mortem examination should be made. The coroner, acting within his discretion, thought it was not called for and declined to make an order. In the first place Dr. Snell was clearly in the wrong. From his own evidence it is obvious that he could not give a certificate of the cause of death, and hence it follows that the body passed into the possession of the coroner, and to make a necropsy without an order was a mistake. The fourth section of the 6 and 7 Will., c. 89, provides that "no fee or remuneration shall be paid to any medical practitioner for the performance of any post-mortem examination which may be instituted without the previous direction of the coroner." It is obvious that Dr. Snell could not legally claim a fee for what he had done without official authority. Could he then be compelled to state the result of his examination? The question is open to argument, but on the whole we are of opinion that, bound by his oath to give in evidence concerning the death "the truth, the *whole truth*, and nothing but the truth," he could not on the ground of professional secrecy decline to divulge the knowledge he had acquired at the post-mortem examination. We are glad to learn that a more conciliatory attitude was assumed towards the close of the inquest and that the coroner eventually made the order claimed by Dr. Snell. It is not our desire to criticise unduly the procedure adopted by coroners, who have frequently a difficult duty to perform, being exposed to the charge of carelessness and parsimony on the one hand and to undue prodigality with the ratepayers' money on the other. After an impartial consideration of the facts we cannot escape the conclusion that Dr. Snell, finding he had overstepped the line of prudence in making a post-mortem examination without an order from the coroner, might have avoided a conflict by timely compromise.

AN UNPLEASANT MISTAKE.

To fondly nurture an egg which only results in the hatching of an ungrateful and venomous reptile is a favourite figure in the pages of fiction and romance, but the figure was almost literally realised in the circumstances of a legal action reported this week. A woman ate what she thought were sweets, when they proved to be those "eggs" which incubate rapidly into a "Pharaoh's serpent" on applying a light. It appears that the plaintiff, a confectioner, purchased from the defendants a number of farthing packets, one of which she sold to a child. The child, however, brought it back, as luckily her father had tasted the contents of the packet and wisely expressed the opinion that they were nasty. The lady confectioner, however, anxious to show

Hosted by Google

that she sold innocuous things, ate one herself, regarding it as a sweet, with the result that she was taken very ill and was medically attended for several weeks. This was the ground of the action, and very justifiable ground too. Unless the confectioner's business was of a mixed kind it is inconceivable that sulpho-cyanide of mercury pills, of which the "eggs" are composed, should be sent to a dealer who sells sweets. Judge Lushington decided that the negligence was on the part of the defendant and not of the plaintiff, and he gave judgment for the latter for the full amount claimed (£50). Sulpho-cyanide of mercury does not appear to be a very powerful poison, and the quantity in each "egg" is stated to be somewhat over a grain. Its poisonous properties may be referred to the mercury rather than to the cyanogen in its composition. On applying a light, however, the vapours given off are very decidedly mercurial, which fact alone suggests that some measure of restriction should be imposed upon the sale of these apparently innocent "eggs."

PROCEDURE UNDER THE SALE OF FOOD AND DRUGS ACT, 1875.

HOPES have been held out that when a number of matters of greater (?) importance than the health of the people shall have been satisfactorily disposed of, the attention of Parliament will be directed to a revision of the laws dealing with the adulteration of food, which have been practically untouched for over twenty years. The Act of 1875 is in many respects open to amendment, especially as to the inadequacy of the penalties for repeated offences, which, as experience has amply shown, instead of acting as deterrents, too often amount to no more than a small tax on enormous illicit profits, and the difficulties often found in obtaining convictions or in reaching the real offender, while instances of hardship are not altogether unknown. But the most serious defect is undoubtedly in the procedure enjoined for obtaining samples, which is uncertain and haphazard, and, indeed, demoralising to all parties. A consciously fraudulent dealer soon learns to recognise as a suspicious customer an inspector, policeman, or other officer or servant of the sanitary authority, and even a woman or child put forward by the inspector waiting outside. The probability of such person being served with an adulterated article is small, although a large business may be done in such goods under other circumstances, and the subterfuges, or, in plain language, the lies, to which a clever and successful inspector is driven to resort are by no means creditable to the law, while often serving to evoke sympathy with the accused, whom an astute counsel may easily represent as the victim of a mean conspiracy. The procedure, too, is applicable to the retail trade only and cannot be brought to bear on the wholesale dealer or manufacturer, who does not sell his goods in small quantities and to all customers over the counter; the only way in which such offenders can be reached being by a further action entered against him by the retailer, and not even then when the latter was a party to the fraud by buying at a price he knew to be incompatible with the purity of the article and of course without a warranty. We would call the attention of those on whom the drafting of a new Bill may devolve to the procedure under the Italian Public Health Act, although we have reason to believe that its provisions are by no means as strictly enforced as they are wisely designed, though this is doubtless the fault of the local authorities and their officials, and not of the able framers of a comprehensive and highly scientific piece of legislation By it the medical officer of health, accompanied, if he prefer, by the public analyst, is empowered to enter any shop, warehouse, or factory, wholesale or retail, for the preparation or sale of any articles of food or drugs, and at his leisure to inspect the entire stock, selecting and taking samples, with prescribed precautions for identification, for examination or analysis. Every element of chance and possibility of evasion is thus precluded, everything is open and fair to all parties, and the opportunity afforded of reaching the wholesale dealer directly is really a protection to the small tradesman, who is as often deserving of pity as of blame.

"SEAMEN'S HOSPITALS."

THE litigation concerning the testamentary intentions of Mr. W. F. Waller of Gravesend, under which a bequest for "Seamen's hospitals" was made to the acting Lord Mayor, is now at an end, and the bank shares—the subject of the bequest—have been transferred to his lordship. The will gives the Lord Mayor absolute discretion in deciding what is a "seamen's hospital," the only condition imposed by the testator being that the money should be applied "for the benefit of such hospitals or hospital for seamen in some or one of the cities or counties which border on the River Thames in England, as he may think fit." The legacy, after payment of legacy duty, will amount to about £9250. Any hospitals for seamen claiming to come within the words of the bequest should send in particulars of their claim to the City Solicitor.

THE PATHOLOGY AND THERAPEUTICS OF SCURVY.

IN our issue of Feb. 13th we referred to Dr. Nansen's experiences with regard to scurvy. Not a single case occurred during the whole time that the expedition was away although the food necessarily consisted very largely of preserved meats. Dr. Torup, Professor of Physiology at the University of Christiania, was of opinion that if meat was badly preserved certain poisons allied to the ptomaines were produced which caused scurvy and consequently great care was exercised in preparing food-stuffs for Dr. Nansen's expedition, with the result already stated. Especially interesting in this connexion is the article recently published by Dr. A. E. Wright, Professor of Pathology at the Army Medical School, Netley. He points out that our knowledge of scurvy is incomplete, inasmuch as it does not furnish us with any explanation of the fact that a regimen consisting entirely of preserved meats and cereals, or of either of these separately, induces the symptoms of scurvy. According to Dr. Nansen's experience, however, this statement must be modified, the word "improperly" being inserted before "preserved." Dr. Wright refers to experiments made by Walther under Schmiedeberg's directions. These experimenters had in view the object of determining the effect of administering mineral acids to animals. The results varied with different animals. In the herbivora there is no special provision for the neutralisation of acids, and consequently rabbits speedily succumb to "acid intoxication" when free acids are administered. This is in conformity with the fact that these animals, so long as they feed exclusively upon herbage, have no need for any such provision, seeing that they are feeding upon alkaline food-stuffs which continually replenish the blood with alkaline salts. In the carnivora there exists a very effectual provision for neutralising acid by means of the waste ammonia of the body, and consequently a dog, for example, bears up perfectly well against even a considerable acid ingestion. Contrary to what happens in the rabbit, the ingested acid does not in the dog either rob the blood of its alkaline salts or diminish its coagulability. Man occupies with respect to his power of neutralising acid a position which is intermediate between that of the dog and the rabbit. He is, therefore, able to bear up without

Hosted by Google

injury against a moderate degree of acid intoxication. If he is plied with acids beyond a certain point the alkalinity and coagulability of his blood will diminish and will finally succumb to the acid intoxication. Dr. Wright suggests that our next step, after we have thoroughly digested these facts, must be to consider carefully what would inevitably happen if this process of setting off the alkalies of our vegetable food against the acids of our animal food were to be forcibly interrupted by the omission of all fresh vegetables and fruits from our dietary. It is obvious to reflection that under these conditions we should inevitably lapse into a condition of acid intoxication. But, again, experience shows that it is precisely under these conditions that we lapse into a condition of scurvy. We may, therefore, at least provisionally conclude that scurvy is a condition of acid intoxication. This theory is supported by therapeutical considerations—namely, the successful treatment of scurvy by fresh vegetables and lime juice. But the recent experiences of Arctic explorers add another important fact—namely, the treatment and prophylaxis of scurvy by administration of blood or of fresh meat with the blood in it. We have consequently to examine this new and important clinical fact and to see whether it can be explained upon the theory that scurvy is an acid intoxication. Dr. Wright does not hesitate to reply to this question with an emphatic affirmative, for he shows that not only is blood an alkaline food-stuff, but that it is comparable in its yield of alkaline salts to lemon and orange juice. We thus see, says Dr. Wright, that the acid intoxication theory of scurvy furnishes us with a complete explanation of the fact that these explorers remained perfectly free from scurvy although they fed on an exclusively animal dietary, for those who have heard or read Dr. Nansen's lectures will remember that bear's blood and fresh flesh were frequently partaken of. This, however, was not constantly the case, and no doubt Dr. Torup's theory and the consequent care expended in preserving the meats had much to do with the immunity from scurvy enjoyed by Dr. Nansen and his companions.

PREVENTIVE MEDICINE AND GEOGRAPHY IN THE "NINETEENTH CENTURY."

THE question as to the expediency or desirability from a professional standpoint of a medical man writing upon medical subjects in the lay journals is a question which must be decided individually and with due regard perhaps to the exact nature of the subject treated of. The diffusion, however, of obsolete opinions or of opinions averse to the best considered practices of the present time cannot be a matter of indifference to the medical profession, nor can errors of elementary geography be altogether ignored in discussions relative to the distribution or progress of any given disease. In the current number of the *Nineteenth Century* is an article on Plague to which the writer must have devoted considerable labour. We read, however, with some astonishment the following sentence: "In China the plague raged from Singapore to Shanghai and Hong-Kong from 1892 to 1896, whence it is supposed to have been carried in bales of cotton to Bombay, where the present outbreak is assuming such grave proportions." As to the conveyance of plague through the agency of cotton bales we may have something to say in another issue, but the position of Singapore is a question which has much disturbed us. We had no notion that this port had been removed to China or that the Chinese frontier had been so extended as to embrace it. Under considerations as to the distribution of plague amongst animals we are told that the cat seems rarely to suffer—an exemption for which its "natural cleanliness" is offered as an explanation. Quarantine, Dr. Lubbock tells us, undoubtedly prevents the importation of plague; but surely numerous instances could be given to show that quarantine has in the past frequently failed in such prevention. The most remarkable portion of the article is, however, that which relates to preventive measures. Most of us have read how in the great plague of London the invaded houses were shut up and the healthy confined with the sick, but it was hardly to be expected that a medical man, even through a lay journal, should in these days advise "isolation of the affected person by closure of the house in which he lives, or, if this is impossible, by placing every suspected case in a special and isolated hospital." It will be noted that the closure of the affected house is the procedure to which preference is given. Science, we are told, "has within recent years taught us the nature of plague." Has it? Dr. Lubbock reposes but little faith in Yersin's serum treatment, since he observes that "medical treatment appears to have little, if any, influence upon the progress of the disease."

A CRUSADE AGAINST DIRTY HOUSES IN BRIGHTON.

UNDER the ægis of the Brighton town council Dr. Newsholme is commencing a new and rigorous crusade—this time against dirty and overcrowded houses. To this cause he attributes the excessive death-rates of certain wards, four of them being 23·2, 22·1, 19·4, and 18·7 respectively, as against 13·9 only in the rest of the borough. Especially is this noticed in the mortality from phthisis, chest complaints, and measles. Dr. Newsholme makes allowances for the accompanying poverty and excessive drinking, and goes on to point out that his present powers of reaching the former evils are dilatory, the compliance temporary and partial, and the evil recurrent. A considerable portion of the offenders are foreigners and he asks for special by-laws. He gives, chapter and verse, the ground for his grumbles—the offending streets and areas and individual cases. He wishes to bring these sub-let houses to the level of common lodging-houses, and he desires to have all the powers under section 90 of the Public Health Act, 1875, which the corporation does not possess under private Acts, for dealing with houses let in lodgings. These, he says, will enable them to reach and partially remedy some of the evils they cannot reach by sanitary inspections. He speaks of the all-round improvement of the last nine years in structural arrangements and adds that these new by-laws are needed to get at the evils for which the tenants are responsible.

A REMARKABLE CASE.

THE *Morning Post* of the 22nd inst. records under the above heading a case with regard to which an inquest was held by Dr. Wynn Westcott. The facts were then stated to have been as follows The patient's husband went to work at 7.30 A.M., his wife then appearing to be in her usual health. When he came back to breakfast at 9 o'clock he found his wife lying dead on the bed, and the body of a child on the floor. Although there was a woman in the next room no sound was heard during his absence. The husband gave evidence that he had no idea his wife was pregnant and, also, that he did not think she knew it herself. On this the coroner remarked that the case was the most remarkable on record. We may say that the woman's death was due to hæmorrhage, and that the child, who is described as having been fully developed, died from suffocation. The case is an interesting and remarkable one, but is far from being unprecedented. As regards unconsciousness of advanced pregnancy in *unmarried* women, though their statements must obviously be accepted

Hosted by Google

with reserve, it seems to have been established that when intercourse has taken place under such circumstances the occurrence of pregnancy appears to the woman to be impossible and she may naturally and in good faith attribute her symptoms to disease rather than to pregnancy. Coming now to the case of a married woman, the probability of her remaining unconscious of her condition in advanced pregnancy is much less, but there is also generally more reason for accepting her statement as true. That a married woman may remain ignorant of her condition up to the time of full term labour is established by Dr. Tanner's case, quoted by Guy and Ferrier, of a woman, aged forty-two years, and three years married, who menstruated scantily for five or six months, and then menstruation ceased for nine months. She was taken in labour and delivered of a mature female child by instruments. Both parents are said to have been anxious to have children, but the woman had no idea she was pregnant and could scarcely believe not only the fact of the pregnancy, but that she had been in labour for ten hours. Another case, the Hawkins divorce case, also quoted by Guy and Ferrier, shows that those about the patient, even her husband sleeping with her till within five minutes of her delivery, may remain ignorant of the pregnancy. In that case the Lord Chancellor was convinced that the petitioner (the husband) had remained ignorant of his wife's condition even in the circumstances above stated. Presumably, in the case on which an inquest has just been held, the husband had been sleeping with his wife till within an hour or so, of her confinement, yet he said he had no idea of her condition, and there seems no reason, such as might have been present in the Hawkins case, for doubting the truth of his statement. The present case is, therefore, extremely interesting; it establishes still more clearly than before the possibility of ignorance of pregnancy existing on the part both of the woman and of her husband up till the very last moment.

MEDICAL POLITICS IN AUSTRIA.

OUR readers will have noticed in the letters of our Vienna correspondent how many of the questions which agitate the profession in England do so as much or more in countries where it is more severely regulated by law than is the case here. Not the least interesting part of his communication in THE LANCET of Feb. 20th is the account of the Austrian medical chambers, which are nineteen in number and scattered through all parts of that country. They cannot be called medical councils. At least, they do not discharge the functions in regard to medical education and registration which our General Medical Council discharges. But they have considerable powers of an ethical kind. Each medical man is required to report himself, with various particulars, to the chamber of the particular district in which he resides. The chambers are not bound too closely or hampered, as our General Medical Council sometimes seems to be, by the hard terms of an Act of Parliament, but can discuss matters relating to the general interests of the profession. They are expected to uphold its privileges, and the courts of law are entitled to ask them for the expression of opinion. Questions of honour and ethics are not decided by the chamber, but by a council of honour composed of from three to seven members. To crown all, the principle of Direct Representation is in full force. The chambers are elected by the medical men of the province or district. It is complained that the powers of the chambers are limited. But there is a power of imposing fines not exceeding £20 on medical men for professional misbehaviour which might well be a very valuable means of bringing erring brethren to better ways, and more merciful than the system of erasure. We have remarked in a previous number on the grave evils in Austria connected with a wholesale State system of insurance against sickness. Such a system means inevitably a cheap system of medical attendance. Hitherto in Germany and in Austria the system has been confined to the working-class; but it is proposed to extend it to employers and tradesmen. So strong is the feeling against such action by the Government that an unprecedentedly large meeting of medical men from all parts of Vienna, numbering a thousand, has been held to protest against it. It is pitiable when a strong Government, which is exacting in its educational demands, interferes in the domain of private practice and caters for those who are quite capable of taking care of themselves. The system threatens to ruin private practice altogether, and we sincerely urge our brethren in Austria to resist it in every possible way. But it is not the State alone that injures the profession. Its own members are scarcely less to blame for joining medical associations which confound the poor and the well-to-do and use methods of low competition which are as inconsistent with the welfare of the patient as with the dignity of the medical practitioner. Dr. Scholz referred to cases in which the practitioner received a penny a visit. Surely the end of such methods must be the rapid degradation of the profession. When Dr. Scholz recommends as a remedy the employment of every man by the State he probably means that the poor for whom the State provides attendance should have a choice of the medical men. Apart from the poor, the more free medical practice is from State control, and the more private and personal the relation between the medical man and his patient the better. The evils so vividly described are to be met by strong organisation in the profession and by a powerful and united protest from all the organisations of the profession to the Government.

THE ENDEMIC FEVER OF THE MEDITERRANEAN.

WE have received a copy of a paper by Surgeon-Captain M. L. Hughes, of the Army Medical Staff, which was read before the Royal Medical and Chirurgical Society in April last and reprinted from the volume of the society's Transactions. As the subject is one of considerable interest, about which a good deal has been written from time to time, we may very briefly call attention to it. The first accurate description of the fever of the Mediterranean, says the writer, was published by Dr. Marston while serving as an army surgeon in Malta in 1861, and since that time it has been written upon by numerous medical officers and others, ending with the discovery in 1887 by Surgeon-Major Bruce of a causal micro-organism. The disease has a wider geography than that implied in its name, for there is reason to believe that the same fever exists on the borders of the Red Sea and probably elsewhere. Surgeon-Captain Hughes describes its symptomatology under three separate groups, the malignant or fatal type, the undulatory, and the intermittent type. He points out its special symptoms, its differential diagnosis from typhoid and other forms of fever, its pathological anatomy, founded on the reports of sixty post-mortem examinations at thirteen of which he was present, and its bacteriology, based upon thirteen cases in which a micro-organism was found by him similar to that described by Surgeon-Major Bruce. The fever commonly runs a very variable but protracted course, and is often complicated with, or followed by, various nervous, rheumatic, or glandular affections, and does not respond to any specific treatment. In fatal cases there is no lesion of Peyer's glands to be discovered. It is often curiously localised to certain rooms in buildings or to certain households and seems greatly to depend upon causes of insanitation—fæcal contamination of soil and air, with warmth and moisture and a drying soil, and insufficient superficial space

Hosted by Google

or ventilation. Change from an enervating Mediterranean climate to this country is generally necessary and always desirable during the warm weather in severe or protracted cases, although it may be preferable for certain cases to remain in the Mediterranean during the winter months in order to avoid the cold of this country at that season.

THE CROONIAN LECTURER AT THE ROYAL SOCIETY.

THE Council of the Royal Society has invited Dr. Sherrington, F.R.S., Holt Professor of Physiology in University College, Liverpool, to deliver its Croonian Lecture this year. The lecture will be given in April and the subject will be the Spinal Cord and Reflex Actions. The official recognition thus extended to Professor Sherrington's work is of a particularly complimentary character inasmuch as it is the custom of the society to invite a foreign *savant* to deliver the Croonian Lecture.

STIVEN *v.* WELSFORD.

WITH reference to our article upon this interesting case it has been represented to us that we have done the defendant an injustice by making it appear as though he had forced the matter into court and had been vindictive in his method of defence. We do not think that any passages in our article bear out such constructions, but we are happy to say that we had no intention of making either suggestion. We are informed that Dr. Welsford was from the first willing to refer differences between Dr. Stiven and himself to medical arbitration, feeling that the issues could be better dealt with by a scientific tribunal.

AFFECTIONS OF THE CAUDA EQUINA.

IN a recent number of the *Archives de Neurologie* there is an abstract of an important lecture on this subject by Professor Raymond. The lecture appeared at length in the *Nouvelle Iconographie de la Salpêtrière*. It commences with a reference to the anatomical relations of the nerves of the cauda and to the muscles and sensory areas which are supplied by them, and two cases are related in which the symptoms briefly were a paralysis, incomplete and limited to certain regions, a similarly circumscribed cutaneous impairment, and interference with micturition and defecation. Certain additional phenomena are also referred to, such as trophic disturbances, sexual impairment, modification of the reflexes, and altered electrical reactions. In regard to sensory changes in such cases the pain is usually situated in the sacral region, radiating into the lower limbs. It is intermittent as a rule, but has not usually the shooting character of the pains of tabes. The anæsthesia is constant, circumscribed, usually symmetrical, and as a rule involves the vesical and rectal mucous membranes and the perineal and pudendal regions, or it may also affect the lower limbs in different ways. Its distribution in the limbs gives an indication as to the roots which are implicated in the disease. Various forms of paræsthesiæ are also present. The motor troubles comprise paralysis and atrophy of certain groups of muscles in the lower limbs, the distribution of the paralysis indicating the nerves affected. Incoördination is unusual as a symptom, although slight unsteadiness is not uncommon. Genito-urinary troubles are always present—i.e., incontinence or retention of urine, and also sexual incompetence. The affections of the cauda equina are either tumours or inflammation. The latter may be of the substance of the conus or nerves or of the meninges, and may be either idiopathic or the result of traumatism, and the treatment to be pursued is either medical or surgical. The medical treatment will be determined by the general conditions affecting inflammations of the spinal cord, and if the diagnosis of tumour can be definitely or even probably determined surgical interference may be successful. More than one case is now on record in which a tumour has been removed from this region. The lecture forms an excellent *résumé* of the symptomatology of this condition, and the two cases related are interesting and illustrative.

THE QUEEN'S COMMEMORATION IN BRISTOL.

BRISTOL is setting a good example in the art of fitly commemorating the notable reign of Her Majesty. At an influential meeting on Monday, presided over by the Mayor, Mr. R. H. Symes, it was proposed, on the motion of Mr. Joseph Storrs Fry, seconded by Sir Charles D. Cave, as a fitting expression of thankfulness for the national benefits accruing from Her Majesty's reign, and as a memorial of her greatness, her worth, and of the services she has rendered to the Empire, to establish a convalescent home for the benefit of the patients of the Bristol Royal Infirmary, and the Bristol General Hospital, at a cost of £50,000, half to be reserved for endowment. A committee was appointed to carry out the undertaking, and some substantial sums were announced at the meeting. No purpose could be more in harmony with the genius of the year. A good convalescent home is now an essential complement of a good hospital, and, as Mr. Fry said, relieves its funds. It is an economical way of treating patients that are advanced in recovery. Besides, it gives them an immense impulse in the recovery of hope and health. The suggestion united men of all political and religious parties in Bristol, and we hope ere long to report its brilliant success.

THE INFLUENCE OF SMALL-POX HOSPITALS.

THE current number of *Public Health* contains an interesting abstract by Dr. Meredith Young on the Local Government Board (Medical Officers') Report, 1894-5. Dr. Young, in dealing with the question of small-pox, points out that though the thesis of the aerial convection of this disease is regarded by the "bulk of authorities" as a settled question there are many still unconvinced, and he draws attention to the experience of Hastings in 1894, where the facts observed form yet another illustration of the danger of placing these hospitals near to human habitations. It was found in that instance that out of thirty-six cases which occurred within 500 yards of the Hastings Small-pox Pavilion the percentage of small-pox attacks to population varied as follows:—

	Attacks.
Within 100 yards circle	4·2 per cent. of population.
,, 100 to 200 yards zone ...	2·7 ,, ,, ,,
,, 200 ,, 300 ,, ,, ...	1·9 ,, ,, ,,
,, 300 ,, 400 ,, ,, ...	0·9 ,, ,, ,,
,, 400 ,, 500 ,, ,, ...	0·2 ,, ,, ,,
Total within 500 yards circle ...	1·3 ,, ,, ,,

Dr. Young adds that the diffusion of small-pox occurred apart altogether from any communication of contagion by infected persons or things, as a most painstaking inquiry showed.

EUCAINE AS A LOCAL ANÆSTHETIC.

EUCAINE, which is, according to Professor Charteris, a "methyl ester of a benzoylated oxypiperidine, carbooxylic acid," possesses some undeniable advantages over cocaine. It is capable of synthetic manufacture and so is cheaper; and it does not possess the mydriatic effect of cocaine. Whether, however, it deserves all the encomium lavished upon it in respect to its greater safety appears open to doubt. Professor Ponchet, in a paper read before the Société de Thérapeutique on Jan. 27th, asserts that eucaine is a powerful cardiac depressant, and in some instances produces sudden death without warning. Injection of 2 milligrammes into a frog caused slowing and irregular action of the heart,

Hosted by Google

while a like dose of cocaine produced no effect. He regards eucaine as inferior clinically and as far more dangerous than cocaine. Upon the other hand, Professor Charteris and Dr. MacLennan recently communicated to the Royal Society of Edinburgh a paper dealing with the physiological action of eucaine, which gives that body a more favourable aspect. Solutions were injected hypodermically into guinea-pigs. A lethal dose of eucaine was found to be 0·09 gramme (per kilogramme of body weight), that of cocaine being 0·068. The phenomena of dying under eucaine showed less head rotation, less opisthotonos, less salivation, and less difficulty of breathing; the symptoms, moreover, took longer to develop than was the case with cocaine, while larger quantities than of the latter were required to produce toxic effects. The influence upon the heart is not mentioned. It must be confessed that we do not at present possess sufficient knowledge of the physiological and clinical behaviour of eucaine to pronounce a definite opinion upon it.

THE "YORKSHIRE POST," "THE LANCET," AND THE LEEDS INFIRMARY.

THE *Yorkshire Post* is certainly one of the best informed and most readable papers in England, but in its criticism of our Special Commissioner's article upon the Leeds Infirmary —the sixth article in the series entitled "Hospital Abuse"[1]—it has done us scant justice. Our Commissioner has sought to collect impartially all the available information bearing upon the subject. For instance, in his first article on Manchester he set forth the arguments adduced by the consultants of that town and by the visiting staff of the hospitals. This practically constituted an indictment of the general practitioners. Then in the subsequent articles he gave the opinion of the general practitioners, which in its turn constituted an indictment of the hospitals and of the consultants. Now at Leeds the principal feature which distinguishes that town from other towns is the influence and powerful organisation of the Workpeople's Hospital Fund. Naturally our Commissioner gave us as fully and as forcibly as possible the arguments and the opinions of this important organisation. Thereupon the *Yorkshire Post*, in a leading article, attacks THE LANCET. If we were to attack the *Yorkshire Post* because of the opinions expressed by a Liberal leader whose speech was reported in the columns of that paper the position would be the same. Our Commissioner seeks to describe all views that bear upon the question of hospital abuse; that does not mean that he approves or that we approve of these views. Such views are held, they exercise a certain influence, and we record the fact. That is all. The *Yorkshire Post* would not refuse to publish one of Mr. Gladstone's speeches, though it is opposed to the political opinions of that statesman. We cannot hope to solve the problem of hospital abuse unless we hear all sides of the question. The *Yorkshire Post* has every right to attack the opinions of the friends and advocates of the Leeds Workpeople's Hospital Fund, but it is not justified in fastening these views upon our Commissioner as if they were his views and his opinions.

THE RE-ENDOWMENT OF GUY'S HOSPITAL.

THE interim report of the Re-endowment and Sustentation Funds in connexion with Guy's Hospital, which has just been issued, shows that the amount received on the re-endowment fund account up to Sept. 30th, 1896, was £161,907 19*s.* 4*d.* Of this sum, £18,826 16*s.* 8*d.* was devoted to the repayment of a loan to the hospital, and the sum of £142,981 2*s.* 8*d.*, less £6364 1*s.* 3*d.*, the expenses of the appeal and of the festival, has been invested in approved securities. The amount received on sustentation fund account up to Sept. 30th, including £13,932 11*s.* 3*d.*, the balance transferred from the old special appeal fund of 1886, was £34,417 11*s.* Of this total certain items amounting to £6965 1*s.* have been transferred to the re-endowment fund. The sum taken from the sustentation fund since its inception to supplement the deficiency in the ordinary income of the hospital was £11,206 13*s.* 10*d.* The appeal has been necessitated by reason of the growing depression in agriculture, the endowment of Thomas Guy, which from 1725 to 1886 provided for all the financial requirements of the charity, having fallen in 1895 to about one-half of its previous value. The treasurer states that of the £500,000 asked for only about one-third has as yet been forthcoming and 150 beds still remain closed.

THE LATE M. BLONDIN.

IT is but a just tribute to M. Blondin on the part of the press to devote a few columns to his unprecedented feats as an acrobat. There was a pluckiness about him which wel became one with his muscles and his nerves, and which was strikingly manifest at both ends of his life—in his childhood, when at nine years of age he was left as an orphan and resolved to look out for himself; and in his advanced age, when, after losing his money, he had to begin the world afresh and repeat the achievements which caused the spectator to hold his breath. His actual feats, including the crossing of the Falls of Niagara, with a man or a lion in his care, or blindfolded, or on stilts, are likely to remain long unrivalled, and perhaps properly so. Meantime they are a record in the region of physiology of simply marvellous command and coördination—of feet with the sensibility of hands and of a brain working with equal perfection in its way. Possibly the most striking thing was the long continuance of his remarkable powers. It is one thing to do such feats at twenty and another to retain the power at seventy or more. And yet so lately as 1896, when he must have been seventy-two years of age, we read that he performed in Belfast. This is the more remarkable, as fully ten years ago, after it is understood, reverses in fortune, Blondin showed unmistakeable indications of physical degeneration. We may question the ethics of such a use of fine nerves and limbs, but we can scarcely question the heroism of the man in battling with life according to his methods and his faculties.

CORTICAL EPILEPSY SURGICALLY TREATED.

Dr. WEISSGERBER has published in the *Münchener Medicinishe Wochenschrift* a paper in which are given the details of two cases of epilepsy with localised fits which were treated surgically. An abstract of the paper appears in the last number of the *Neurologisches Centralblatt*. The first case was that of a boy, aged ten years, who at the age of one and a half years had sustained a compound fracture of the skull. Several pieces of bone came away before the wound healed. In June, 1891, and in August of the same year the two first attacks, characterised by movement of the left upper and lower extremities, took place, and these were succeeded by recurrences taking place every eight or ten days and lasting for two or three minutes at a time. An operation was carried out dealing with the site of the old scar. A defect was found in the bone and adhesion of bone, dura mater, and brain. These were all removed or separated, even part of the cortex being taken away. Rapid healing took place and the boy remained for two years without an attack, and he has remained since April, 1894, quite free from fits and in a satisfactory mental condition. The second case was that of a man aged

[1] THE LANCET, Feb. 13th, 1897.

Hosted by Google

twenty-eight years, who at the age of ten years had received a blow on the head which was followed by prolonged suppuration. A few weeks after the accident there were cramps in the right arm and afterwards weakness of that and of the corresponding leg, with headache. A year later all these symptoms disappeared. At the age of seventeen years Jacksonian attacks became established, commencing in the right side, but affecting also the opposite one, and the scar on the head simultaneously became painful. The attacks occurred frequently, and finally operation was undertaken. There was found a considerable defect in the skull and underneath this a cyst containing clear fluid. Some of the bone was taken away, the dura mater was separated, and the cyst wall with part of the brain substance removed. The attacks remained in abeyance for four weeks and then recurred about once in five weeks, but the patient had at the time of writing been quite free from them for more than eighteen months.

BELGIAN GUARDIANS CLAIM MEDICAL RELIEF FOR THEMSELVES.

THE effrontery—not to say dishonesty—with which well-to-do people continue to obtain medical attendance for little or nothing is, of course, not confined to this country. Indeed, in many parts of the Continent matters are probably even worse than with us. Thus, the medical practitioners residing in a certain district in Belgium have recently drawn up a list of persons who have the right to gratuitous attendance, but who are quite able to pay for it. The very modest demand that such people should no longer be authorised to laim the services of the district medical officer has met with a refusal and the grievance is now being discussed in the political journals. From the correspondence published we learn that for the last twelve years the medical men in the district have had grave cause of complaint regarding the medical attendance on the poor — for which a fixed yearly salary is paid — inasmuch as the list of "poor" has been drawn up so as to include nearly all the well-to-do people in the place, including shopkeepers, farmers, and most of the guardians of the poor and communal councillors themselves (!) which is said by the writer to be definitely illegal, as, of course, it ought to be. No wonder that there should be some difficulty about getting the list revised. It appears that the whole of the local profession is now determined to make a stand against this injustice.

THOMSEN'S DISEASE.

AT a recent meeting of the Berliner Gesellschaft für Psychiatrie und Nervenkrankheiten, of which an account appears in the *Neurologisches Centralblatt*, Dr. Pelizaeus showed an interesting example of this peculiar disease, offering, however, some marked differences from the usual type. The patient was twenty-seven years of age and had come from a healthy family. His trouble began at the age of sixteen years, and now his muscles showed considerable departure from the normal. There was not the universal over-development of those which is met with in most cases of myotonia, for some of them actually showed an atrophic condition, as the deltoid and the muscles of the ball of the thumb on both sides. If the patient extended the arm or hand he could in a comparatively short time flex them again, but if he first flexed them extension required both time and considerable effort. There were also symptoms of some bulbar affection, his articulation having a nasal character, and on an attempt to blow out a light air came through the nose and there was a marked tendency to choke, especially in swallowing liquids. The affection seemed to be a progressive one, and a sister of the patient, aged twenty-one years, was similarly affected. In the discussion which followed, Professor Jolly mentioned a case of muscular atrophy which he had shown at the society, which afterwards became one of Thomsen's disease; and Professor Remak mentioned a case published by Professor Hoffmann in which there was neuritis of the median nerve, possibly from the severe pressure of the contracting muscles. There seems to have been a general agreement that the case shown was really one of Thomsen s disease.

CHEAPENING THE CARRIAGE-RATES FOR CIDER.

THE first great step towards the revival of the cider industry has been accomplished in the promise of the railway company serving the Herefordshire district to convey cider at a cheap and special rate. This should give a distinct impetus to the revival of a once important industry, since the high cost of distribution is a powerful factor against success. It is hoped that the same proportionally low scale of rates will be conceded also by other companies. The whole movement is not a fad, but one of national importance as tending to promote the availability and use of an undoubtedly refreshing and wholesome beverage, and we congratulate Mr. Radcliffe Cooke on the evident progress he is making towards this end.

A SUBLIMELY RIDICULOUS STATEMENT.

"THE sublime and the ridiculous," says the *Medical Press and Circular*, "seem to be curiously illustrated in the regulations, written and unwritten, which belong to the Royal College of Physicians, London." Our contemporary then proceeds to state that no Fellow or Member of the College is permitted to publish anything on syphilis, understanding that "only recently a Fellow of the College was severely taken to task by the President for having so far offended against the traditions of the College as to publish an important communication upon the forbidden subject." Were it not that the rest of the article is peppered over with such adjectives as "grandmotherly," "narrow," "illiberal," "fatuous," and "ignoble," we should have supposed the *Medical Press and Circular* to be poking fun at the profession. But thus to abuse the College on false grounds would be carrying fun to such an indecent length that we are forced to believe that our contemporary has been made the victim of a hoax by one of its contributors. If so, the hoax is all the more cruelly opportune because on Tuesday last the Royal College of Physicians of London appointed a strong committee to inquire into the working of the Contagious Diseases Acts in India, and a knowledge of syphilis will be expected of each gentleman selected to serve. The present President of the College has sat on two such Commissions previously, and, as a further reason why Dr. Wilks should not "take seriously to task" any Fellow or Member of the College for dealing with the subject, we may remind our readers that he himself published a lecture on syphilis—and a very admirable discourse, too—in our columns in 1867. This lecture was delivered to the students of Guy's Hospital, and the very first sentence lays down the obvious truth that constitutional syphilis must be regarded as, "strictly speaking, a medical disease." How does the *Medical Press and Circular* think that diseases of the nervous system, for instance, are to be treated if the subject of syphilis may not be mentioned by the physician? We hope that our contemporary will see the fitness of expressing some regret for its misapplied abuse of the Royal College of Physicians of London.

A COPY of the memorial to be presented to the Royal College of Physicians of London by the Hospital Reform Association has been sent to us by the honorary secretary of the association and lies for signature in our offices.

OWING to some misapprehension we are asked to state that the memoir contained in the volume of "Essays and Addresses by Sir John Russell Reynolds," recently published, was written by Dr. Squire Sprigge.

THE anonymous benefactor who has undertaken to re-build and extend the University College Hospital in Gower-street, London, at a cost of £100,000 is now formally stated to be Sir J. Blundell Maple.

LORD LISTER, who was introduced by Lord Watson and Lord Playfair, on Tuesday last took the oath and his seat in the House of Lords on his elevation to the peerage.

THE two vacancies in the Executive Committee of the General Medical Council have been filled by the appointment of Mr. Brudenell Carter and Dr. Glover.

WE understand that Surgeon-Major Horace Pinching has been appointed Medical Officer to Mr. Rennell Rodd's Mission to King Menelik.

THE Duke of Bedford has accepted the office of President of University College Hospital.

THE INTERNATIONAL SANITARY CONFERENCE.

SPEAKING of the International Conference at Venice in THE LANCET of the 13th instant we alluded to the different standpoints from which the delegates from this Government and their Continental *confrères* would probably regard the question of quarantine and international precautionary sanitary requirements. We pointed out that if our experience had taught us to lean with more confidence on sanitary preparedness than on strict measures of quarantine, sanitation, nevertheless, in its broadest and best sense, was necessarily of slow growth, and meant time and money, and that Continental nations with the enemy at their door very naturally sought to close the door and endeavour to exclude the foe by those severely restrictive measures of quarantine on the efficacy of which they relied; and we added that we hoped all the delegates would approach the discussion of the questions to be considered by them in a dispassionate and eminently conciliatory and reasonable spirit. If that were done we confidently believed that some practical line of action would be the result of their deliberations. It is very gratifying, therefore, to find that this spirit appears to have animated the members of the conference in all the proceedings which have so far taken place.

The opening sitting was held at the Royal Palace at the western end of the Piazza San Marco on the afternoon of February 16th, when some fifty delegates, representing all the principal Powers, were present. Surgeon-Colonel Richardson appeared on behalf of the Indian Government pending the arrival of Surgeon-Major-General Cleghorn from India. The opening day's proceedings were mainly of a formal and complimentary character. Count Lützow, Austrian Minister at Dresden, after returning thanks for the delegates to Count Bonin Longare, Under-Secretary of State for Foreign Affairs, for his welcome in the name of the King of Italy, proposed Count Bonin as President, which was unanimously agreed to.

The subsequent progress of the proceedings of the conference from day to day has been satisfactory, and considerable advance has been made towards the settlement of several vexed questions. Without taking up all the points stated to have been raised for discussion, which would prove a tedious and impossible task, we must content ourselves with touching upon the more salient of them. First, then, as regards the ratification of the Paris Convention of 1894, Mr. Herbert, the diplomatic representative of Great Britain, announced the readiness of the English Government to ratify the Convention with three reservations, the details of which he stated to the Conference. The announcement made a most favourable impression upon the Conference and is regarded as an earnest of British goodwill towards the cause of international sanitation.

The reports which have appeared in the *Times*, from their special correspondent at Venice, have been particularly full and interesting, and we cannot do better than follow the account of the proceedings of the Conference that have been published in the columns of that journal. Judging from a week's proceedings the present Sanitary Conference, says the *Times* correspondent, is a decided improvement on its predecessor as regards the conciliatory spirit of all the delegates. The Austrians and French in particular have manifested towards England and the Indian Government a degree of consideration which is warmly appreciated and reciprocated. Count von Lützow and M. Barrère, the Austrian and French diplomatic representatives, have shown themselves especially anxious to promote a good understanding, while the technical authorities, such as Professor Proust, Professor Brouardel, and Dr. Thorne Thorne, have been no whit behind the diplomatists. The issue of the present conference is civilisation *versus* plague rather than theoretical prophylaxis *versus* commerce, as has been the case on some previous occasions. The action of the English Government with regard to the ratification of the Paris Convention has stimulated these friendly feelings and enhanced the probability of the Conference being thoroughly successful. The only obstacle to the application of the Paris Convention is Turkey, which country is without a diplomatic representative at Venice. Since the provisions of the Convention would affect Turkish territory more than that of any other country the ratification of the Convention by the Porte is almost a *sine quâ non* of its efficacy. Energetic efforts are being made to obtain a reply from the Porte, and the Conference will probably sit until such reply is forthcoming. In the event of a refusal measures of sanitary or commercial coercion might be devised.

Surgeon-Major-General Cleghorn, the representative of the Indian Government, joined the Conference on the 20th inst., and his arrival brought up the total number of delegates to sixty-five. The delegate from India gave a detailed description of the precautionary sanitary measures in force at Bombay and Karachi since October last, and his observations are stated to have created a favourable impression. He was able to assure the Conference that there was a rigorous individual examination of all pilgrims on shore before embarkation and of passengers on board their vessels before starting. The work was executed by a large staff of male and female medical practitioners, twenty of whom were engaged on the steamer which brought him from Bombay to Brindisi. The impression entertained by the most competent authorities is that the danger of the introduction of plague into Europe has been greatly exaggerated, and the probability of its conveyance by merchandise very small; indeed, the probability of plague being transmitted from India is much less than in the case of epidemic cholera.

Two sub-committees have been organised to consider the means for combating the plague outside Europe and to concert measures of defence in Europe respectively, and these bodies have already passed in review a number of propositions of a more or less technical character with regard to some of which practical conclusions have been agreed upon.

THE BARKER PRIZE.—The Royal College of Surgeons in Ireland announces that a Barker Prize of £26 5*s.* is offered for competition and is open to any student whose name is on the anatomical class list of any school in the United Kingdom. The prize is offered for a dissection of the region in front of the sterno-mastoid above the cricoid, with special relation to lateral pharyngotomy, the removal of tonsillar tumours and of infiltrated glands in cancer of the tongue. The preparation must be sent to the curator of the museums, Royal College of Surgeons in Ireland, before June 1st, 1897, marked with a *nom de plume* and accompanied by a sealed envelope bearing outside the same signature and containing within (*a*) the full name of the competitor, and (*b*) a declaration that the work of the preparation has been carried out by himself; the printed form necessary for this declaration can be obtained from the curator. The dissections are to be mounted in vessels fitted with glass covers, but the covers must not be sealed down. The cost and risk of transport must be borne by the student. The prize will not be awarded unless sufficient merit is shown.

The Lancet Special Commission
ON
THE METROPOLITAN WATER-SUPPLY.

II.[1]

WEST MIDDLESEX WATERWORKS COMPANY.

IN the early part of the present century an engineer named Dodd projected some new waterworks to supply the West-end of London, and in the year 1806 an Act was passed to allow the scheme to be carried out. Hammersmith, Kensington, Paddington, and part of Marylebone were to be supplied, and Mr. Dodd's original plan was to make the works at Hammersmith, but later he wished to have them at Poole's Creek, near Fulham. The shareholders of the company disapproved of the change of plan. Mr. Dodd left their service, and in 1807 a new engineer was employed and the works were constructed at Hammersmith as originally proposed. Wooden pipes were at first used for the conveyance of the water and stone ones were afterwards adopted, but as these proved unsatisfactory cast-iron pipes were substituted in the following year. In 1809 land was bought on Campden-hill and a reservoir capable of holding over 3,500,000 gallons was constructed there. This was done with the intention of supplying parts of the district of Marylebone, but difficulties were placed in the way of this extension. The original Act of Parliament authorised the company to supply "certain parishes and places as well as parts adjacent." The company construed the expression "parts adjacent" to mean the whole of Paddington and Marylebone, but the select vestry of Marylebone objected to the pavements being taken up for laying the pipes. In 1810 the company obtained an extension of their authorised area of supply and this difficulty was therefore overcome. In 1825 a reservoir was built on Barrow-hill, near Primrose-hill. It was constructed to contain 4,750,000 gallons of water and was situated at an elevation of 190 ft. above ordnance datum. This reservoir was supplied from Hammersmith. In 1838 subsiding reservoirs were made at Barnes and the water from them was taken to the engines at Hammersmith through a pipe laid in the bed of the river. An Act of 1852 (15 and 16 Vict., cap. 159) provided that water for the supply of London should not be taken from the tidal portion of the Thames. The West Middlesex Company selected Hampton for their new station, the intake was removed, and engines were put up to pump water to the subsiding reservoirs at Barnes. These works were completed in the year 1855. Filter beds were made at Barnes and the reservoirs at Barrow-hill and Kensington were covered over. In 1860 the filtering area was enlarged and the pumping power increased. In 1866 the company obtained leave to supply parts of Hampstead, Hendon, Willesden, and part of Acton, in the county of Middlesex, and a reservoir was made near the Finchley-road 323 ft. above ordnance datum. Afterwards a second 36-in. conduit was laid across the Thames from Barnes to Hammersmith, and a covered reservoir was constructed at Willesden. In some of the districts a constant supply of water was given in 1872. In 1886 the Thames Conservancy entered into an agreement by which the company was allowed to take from the river 4,500,000 gallons of water in addition to the 20 000,000 gallons which they had previously taken. In 1896 large reservoirs were completed at Barne Elms and two others were begun.

FIG. 1.

The Reservoirs and Filter Beds of the Company at Barnes.

General description.—The West Middlesex Waterworks Company's area of supply includes Hammersmith, Earl's Court, the Regent's-park district, Portland Town, Kilburn, Child's-hill, Willesden, and extends as far north as Hendon. The district supplied by the company is bounded on the west by the Grand Junction district, on the south partly by the Chelsea district and by the Thames, and on the east by the New River Company's area of supply. The company's stations are—Hampton, intake; Barnes and Barn Elms, reservoirs and filter-beds; Hammersmith, pumping station; Campden-hill, reservoir; Barrow-hill, pumping station and reservoir; Kidderpore, reservoir; Willesden, pumping station and reservoir; and Shoot-Up hill, reservoir.

Hampton.—The intake is at Hampton from the Thames.

[1] No. I. was published in THE LANCET of Feb. 20th, 1897.

Hosted by Google

The unfiltered water is pumped through mains which pass through Twickenham, cross under the Thames at Richmond, then run through Mortlake and Barnes, where the storage reservoirs and filter-beds are situated. From Barnes the filtered water crosses the Thames to Hammersmith and is pumped thence to the district in the immediate neighbourhood and the reservoirs at Campden-hill (Kensington), Barrow-hill (Primrose-hill), and to Willesden. There are also reservoirs at Kidderpore (Hampstead) and Shoot-Up-hill, and these are supplied by pumping from Barrow-hill and Willesden.

Source of water.—The whole of the water supplied by the company is taken from the Thames at Hampton. The water first passes through a coarse-meshed iron screen placed in front of an intake bay. The bars of the screen are placed ¾ in. apart. The width of the inlet is about 30 ft. and the height of the Thames is regulated by the Thames Conservancy, so that the water does not fall to a lower level than 2 ft. from the top of the pipes. There are two mains each 48 in. in diameter. The water first passes into a screen-house.

Screen-house.—The water passes through two screens of galvanised iron, of which the meshes are ¼ in. These screens prevent small leaves and other débris from passing in. They are arranged so that they can be drawn up to be cleaned; the cleaning is done with a broom, always once a day, and more frequently if necessary. From the screen-house the water passes in two 48-in. mains to a circular shaft 20 ft. in diameter, from which the water is distributed to the various engine wells.

Engine-house.—There is one of Simpson's horizontal engines, which is capable of pumping 24,000,000 gallons of water a day to Barnes. The steam is generated by five Cornish boilers. The second engine-house contains two vertical Worthington engines, each of which is capable of pumping 16,000,000 gallons a day to Barnes. The steam for these engines is supplied by four Lancashire boilers, and the arrangements are such that any of the engines can be worked by either set of boilers. There are no subsidence reservoirs or filter-beds at Hampton, but the water, after passing through the screens which have been described, is pumped direct to Barnes.

Course of the mains.—Two 36-in. iron pipes convey the water along the high road to Richmond. At Richmond they go under the river a few yards below the bridge and then along the high road to Barnes. There is a connexion with the Southwark Company's mains opposite the Black Horse public house at Marsh Gate, near Richmond.

Barnes and Barn Elms.—The subsidence reservoirs and filter-beds are all situated at Barnes, where the company possess one hundred and ninety-six acres of ground near the banks of the river. (See Fig. 1.)

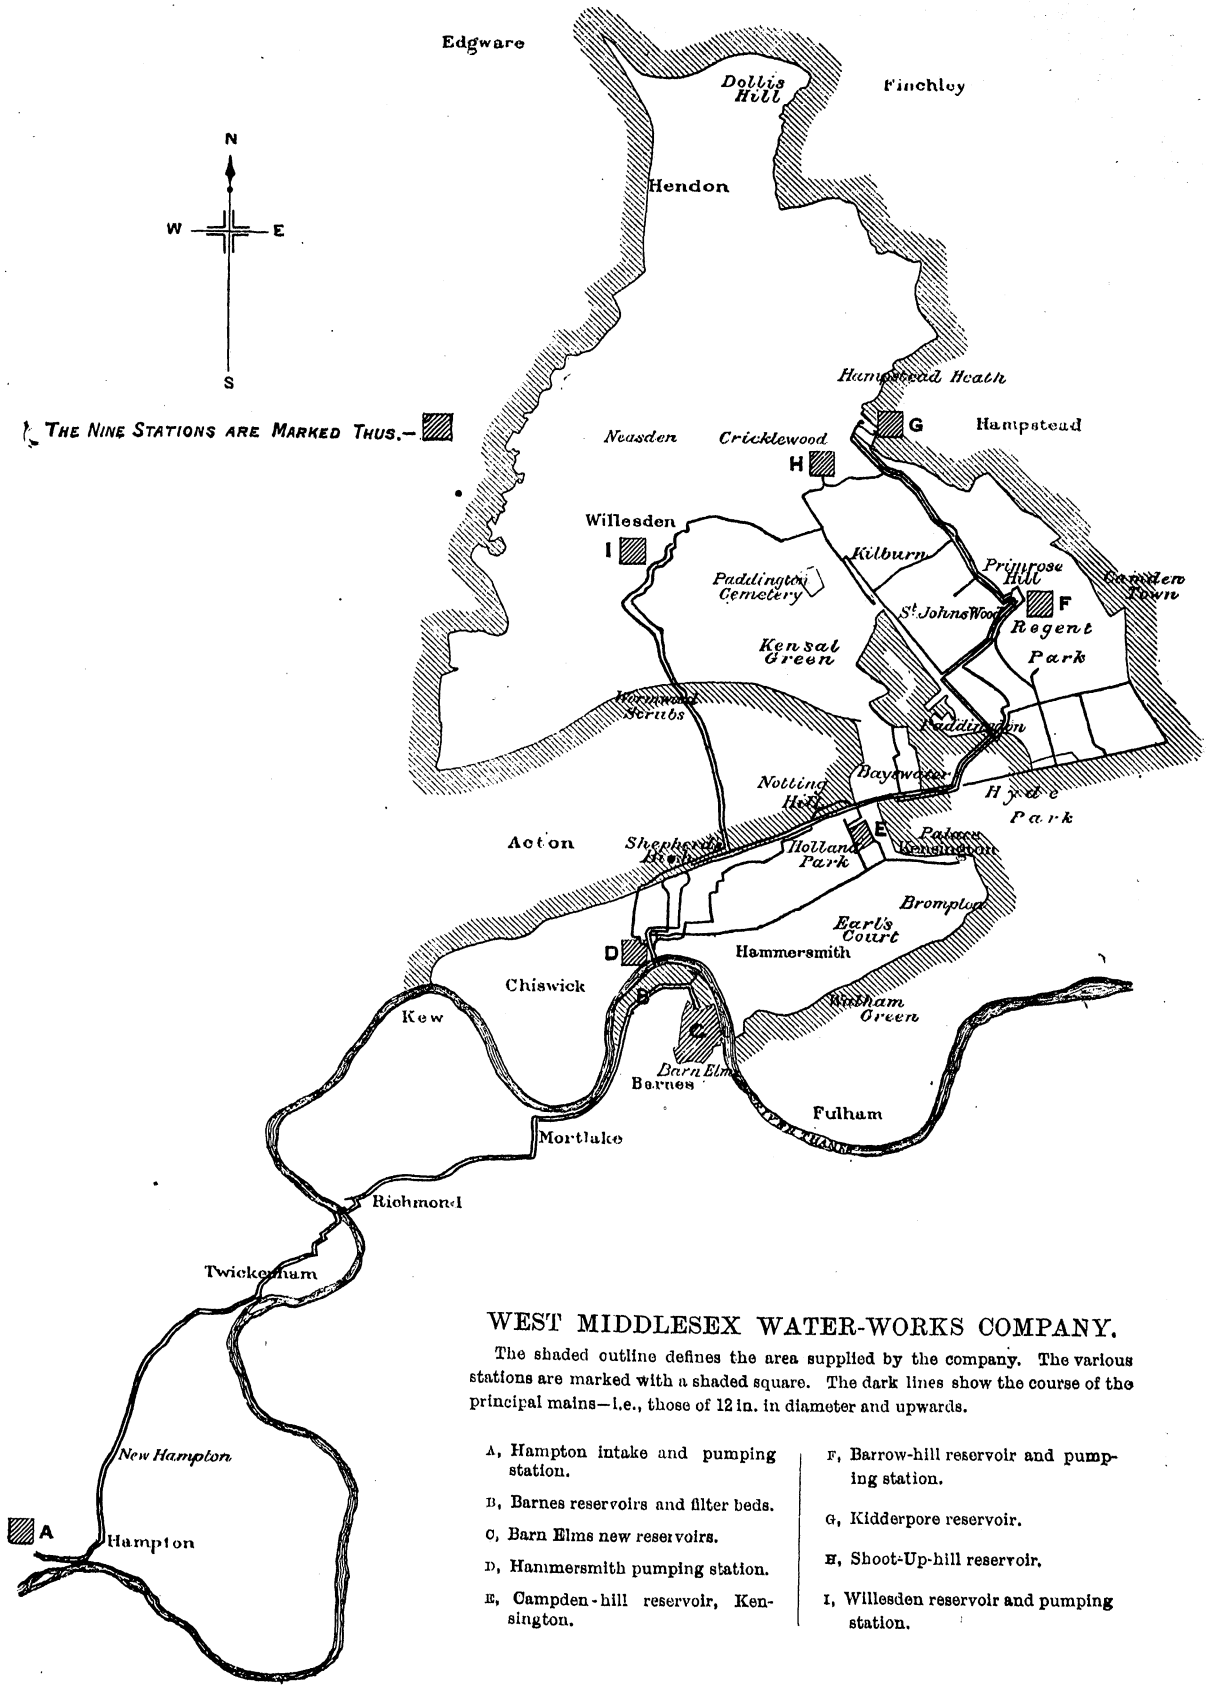
Subsiding reservoirs.—There are now in use six subsiding reservoirs. Into the first reservoir the water passes through a bell-mouthed opening, and the water flows out after the manner of a miniature fountain. This arrangement was devised by the late Dr. Tidy to ensure that the water should become aerated as much as possible. The area of this reservoir is seventeen acres and it is capable of storing 57,000,000 gallons of water. From the first reservoir the water passes to the second, which is at a lower level, the fall being 4 ft. 6 in. Some of the water falls over in the form of a cascade, but the greater part passes through a tunnel. The second reservoir has an area of about five and a half acres and a storage capacity of 17,750,000 gallons. The third reservoir is at the same level as the first, has an area of about seven acres, and a storage capacity of 18,750,000 gallons. A caretaker's cottage is situated between these three reservoirs. A fourth reservoir, situated near Hammersmith Bridge, has an area of about seven and a half acres and a storage capacity of 24,000,000 gallons. Two other large reservoirs have just been completed at Barn Elms. These have an area of about fifty acres and are capable of containing 167,000,000 gallons of water. The slopes forming the sides of the new reservoirs are lined with concrete and brick at the upper part, and at the top of the slope is a flat berme and a breast wall. This arrangement is designed to prevent the water from being blown over in windy weather.

Filter beds.—The filter beds are situated between the Lonsdale-road and the river and between the third and fourth reservoirs. The number of the filter beds is eleven and their total area fifteen acres. Nos. 1, 2, and 3 have an area of one and one-third acres; No. 4 has an area of two and a quarter acres; No. 5 has an area of one and three-quarter acres; Nos. 6a and 6b have an area of one acre each; No. 7, 8, 9, and 10 have an area of one and one-sixteenth of an acre each; and No. 11 has an area of one acre. The filtering material consists of 2 ft. 6 in. of sand resting on 1 ft. of ballast. The only difference in the arrangement of the filters is that for the collection of the filtered water. The greater number of them have earthenware collecting drains, placed at intervals of 30 ft., to conduct the water to the central collecting channel. Four of the filters (Nos. 7, 8, 9, and 10) rest on square earthenware tiles, which are placed quite close together. The remaining filter (No. 11) is floored with stones and has no collecting channel except the central one. The size of the ballast varies from about ⅛ in. up to 2 in., the smaller ones being placed at the top and the larger ones at the bottom. The rate at which filtration is carried on is on an average one and one-third gallons per square foot per hour. After filtration the water passes under the Thames in two 36-in. iron pipes to Hammersmith pumping station. The pipes can be seen in the bed of the Thames at low water, and it is proposed shortly to construct a tunnel in the clay under the Thames and to run the pipes in this.

Hammersmith.—The chief pumping station is at Hammersmith, whence the water is distributed into the district, to the reservoir on Campden-hill, and the subsidiary pumping stations at Barrow-hill and Harlesden. From Barrow-hill the water is pumped to Kidderpore and to Shoot-Up-hill, if required. From Willesden it is re-pumped for the supply of Shoot-Up-hill reservoir. At Hammersmith there are four Cornish engines capable of pumping 14,000,000 gallons into the district daily. There are three compound beam engines capable of pumping 13,500,000 gallons a day. There is also a compound Worthington engine which can pump 5,500,000 gallons a day, and two triple expansion Worthington engines capable of pumping 3,500,000 gallons. The steam is generated by thirty-two Cornish boilers.

Campden-hill, Kensington.—The reservoir is situated at an elevation of 120 ft. above ordnance datum on the eastern slope of Campden-hill rather below that of the Grand Junction Company, which is situated on the other side of the road, (and is marked by the tower which is a conspicuous object from a distance) The reservoir is built of brick, and is not covered with earth at the top. It is capable of holding 3,762,000 gallons of water, which is pumped here from Hammersmith. One 21-in. main from Hammersmith passes down the South side of the Company's property. The overflow from the reservoir passes into a brick drain of about 2 ft. by 1½ ft. There is a house for the assistant engineer and a cottage for the turncock here.

Barrow-hill.—The company's station on Barrow-hill is next the open space on Primrose-hill. The height above ordnance datum is 190 ft. There is a covered reservoir built on arches capable of holding 4,750,000 gallons of water. As to engines, there is a single cylinder beam engine capable of pumping 1,200,000 gallons daily, a single cylinder horizontal engine capable of pumping 1,750,000 gallons, and a compound horizontal fly-wheel engine capable of pumping 2,930,000 gallons daily. The engines are worked by six Cornish boilers. The assistant engineer's house and two cottages are situated at Barrow-hill.



Shoot-Up-hill.—On the plateau at the highest point of Shoot-Up-hill is a reservoir built on arches. It is 250 ft. above ordnance datum and is capable of holding 6,000,000 gallons of water. Water can be supplied to this reservoir either from Willesden or from Barrow-hill (Primrose-hill). The quantity of water taken is regulated by a 16-in. screw cock situated at the bottom of the hill. This reservoir formerly belonged to the Grand Junction Company.

Kidderpore.—At an elevation of 323 ft. above ordnance datum there is a reservoir capable of holding 2,500,000 gallons. The reservoir is covered in with brick arches and the roof is not earthed over. A caretaker's cottage is situated here.

Willesden.—At Willesden there is a pumping station and a reservoir. There are two compound horizontal fly-wheel engines capable of pumping 2,000,000 gallons each daily. The steam is generated by two Cornish boilers. The water is pumped to Shoot-Up-hill. The reservoir which is situated 190 ft. above ordnance datum and is covered by strong brick arches and earth, is capable of holding 2,500,000 gallons.

Length of pipes.—In 1895 16,708 yards of new pipes, ranging from 3 in. to 48 in. in diameter, were laid. In 1896

the length was 16,723 yards. The total length of pipes on Dec. 31st, 1896, was 480 miles.

Number of hydrants.—The number of hydrants erected in 1895 was 156, and in 1896 was 204. The total number on Dec. 31st, 1896, was 942.

Communication with other companies' mains.—Filtered water—Grand Junction: (1) at the junction of Edgware-road and Bayswater-road; and (2) at Kilburn. New River: (1) at the junction of Tottenham-court-road with Oxford-street; and (2) at the junction of Tottenham-court-road with Euston-road. Unfiltered water—Southwark and Vauxhall: at Marsh-gate, near Richmond.

Houses under constant supply.—The number of houses receiving constant supply on Dec. 31st, 1894, was 50 985; on Dec. 31st, 1895, 55,933; and on Dec. 31st, 1896, 64,701.

Total number of houses supplied.—The total number of houses supplied on Dec. 31st, 1894, was 78,486; in December, 1895, 79,644; and in December, 1896, 80,697.

Percentage of houses under constant supply.—On Dec. 31st, 1896, the percentage of houses under constant supply was 80.

Average daily supply.—In 1895 the average daily supply per head was 35·66 gallons. In June the maximum was attained, the amount per head being 40·59 gallons, and the minimum occurred in the month of February the amount per head being 31·52 gallons. In the year 1896 the average daily supply was 34·5 gallons. The maximum supply was given in July and amounted to 39·8 gallons per head. The minimum supply was given in December and amounted to 31·3 gallons per head.

Area of Supply.

The Act of 1852 authorises the West Middlesex Company to supply the following places:—

Partly supplied.—Chelsea (St. Luke, west of the boundary defined in the Act[2]), Chiswick (St. Nicholas), Ealing (St. Mary), Fulham (All Saints), Hammersmith (St. Paul), Kensington, (St. Mary Abbott), Paddington, Soho (St. Anne), St. Marylebone, St. Pancras (south of Fig-lane), Westminster (St. Margaret), and so much as lies within the town of Kensington.

Not supplied.—Barnes (St. Mary), Battersea (St. Mary), Bloomsbury (St. George), Brentford (Old), Brentford (New), Hanwell (St. Mary), Heston, Hounslow, Isleworth, Kew (St. Anne), Mortlake, Putney (St. Mary), Richmond (St. Mary Magdalene), Strand (St. Mary-le-), St. Clement Danes, St. Giles-in-the-Fields, St. Paul (Covent-garden), Westminster (St. James), and Wandsworth (St. Mary).

The Act of 1866 authorises the supply of Willesden, which is wholly supplied. Partly supplied: Acton (north of Great Western Railway), Hendon, and St. John (Hampstead).

New Works in Progress and Projected.

Reservoirs.—At Barn Elms two large reservoirs are in course of construction and will be completed in the early spring. They are situated near to the new ones described and are constructed on the same plan. They will be capable of storing 133,000,000 gallons of water.

Tunnel under the Thames at Hammersmith.—It is proposed to make a tunnel under the Thames between Barnes and Hammersmith for the conveyance of the mains which carry the filtered water under the Thames.

ERRATUM.—By an obvious error the word "Chelsea" was written for "Lambeth" in the description of the map on page 543 of THE LANCET in last week's issue. The map is perfectly correct.

---

[2] Section 32 of the West Middlesex Waterworks Act, 1852, is so framed as to enable the Chelsea Company to exact a penalty from the West Middlesex Company in the event of the latter supplying within a certain defined part of the eastern portion of the parish of Chelsea.

THE ANTI-TOBACCO LEAGUE AND JUVENILE SMOKING.—The members of the English Anti-Tobacco Society and Anti-Narcotic League met recently in Manchester to the number of about a score. A letter of apology for absence was read from Mr. S. Smith, M.P., in which he said that he thought there would be no chance of passing the Bill suggested by the League to prevent juvenile smoking, but if any member liked to introduce it he would be glad to put his name to the back of the Bill. Dr. Martin of Manchester read a paper on Juvenile Smoking, in which he dealt with the injurious physical effects of the habit.

ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1895.[1]

[CONCLUDING NOTICE.[2]]

AMONG the diseases that were unduly prevalent during the year 1895 among the troops stationed in the colonies may be mentioned enteric fever at Bermuda, malarial fever at Mauritius, and venereal diseases in the Straits Settlements. At Bermuda in an average strength of 1447 enteric fever caused 107 admissions and 20 deaths, equal to ratios of 73·9 and 13·82 per 1000, considerably higher than the average rates for the previous nine years. The disease appeared early in June at Warwick Camp, being conveyed thence, it is believed, to other stations in the command. At St. George's, where the drains were defective and the drainage works had been suspended owing to the great heat, the disease seems to have partaken of the nature of a severe outbreak, for there were 46 admissions to the station hospital there and 13 deaths. There should not be any great difficulty, with proper attention to water-supply and to the prevention of the leakage of sewage from drains and cesspits into the soil, in preventing the frequent recurrence of those outbreaks of enteric fever in Bermuda. We suspect, from what we have heard, that much of the disease of the digestive system at this station is attributable to food and cooking; the supply of food is not sufficiently good and varied; it is also apt to become tainted in such a hot, moist climate and the cooking is far from the best imaginable.

The Mauritius is a very unhealthy station owing to malarial fevers. Happily, the average strength (657) is small. Enteric fever caused 15 admissions and 6 deaths during 1895, but malarial fevers were the greatest cause of sickness. There were 460 admissions and 3 deaths—equal to ratios of 700·1 and 4·57 per 1000 respectively. The cases were returned as follows: ague 294, remittent fever 159, and malarial cachexia 7; 2 of the deaths were due to remittent fever and 1 to malarial cachexia. The invaliding-rate was also a heavy one. For very many years past the Mauritius has been a most unhealthy station as regards malaria—a very marked change in this respect having taken place since the severe and fatal epidemic of malarial fever that occurred over a quarter of a century ago at the time when Sir Henry Barkly was governor. Port Louis is particularly bad in this respect, and will continue so, it is feared, until extensive works are undertaken for subsoil drainage. Curepipe, in the uplands, is far healthier, and the troops are as far as possible quartered at this and other stations in the island.

As regards the Straits Settlements the amount of venereal disease among the troops is deplorable. Including all its forms the admissions amounted to 853, the number constantly sick to 62·55, more than half the admissions and constantly sick from all causes. The admission ratio was 623·5 per 1000 in 1895, which is higher by 257·6 than the corresponding rate of the previous year and above the average rate by 210·0. A good deal of this increase, it should be remarked, was attributable to a battalion having arrived during the year from India, bringing the disease with it. The reports of the medical officers make no allusion to anything else affecting the health of the troops.

As regards India our comments and remarks must be brief. Enteric fever caused 1544 admissions into hospital, 383 deaths, and the constant sickness of 219 77 men, being in the ratios of 22·6, 5 61, and 3·22 per 1000 respectively. This disease was rife among the troops, by the way, on the route to and from Chitral. A good deal is being said at the present time about the large prevalence of venereal diseases in India. Taking all forms together, the ratio of admission amounts to 536·9 per 1000, which is more than that of the preceding year by 25 2, and in excess of the average rate by 127·6, while for constantly sick the ratio was 46·31, representing a loss of 3164·84 men to the efficient strength of the force from these diseases, higher than the rate in 1894 by 3·17, and above the average by 14·39. The reports of several medical officers dwell upon the virulent type of the disease,

[2] The first and second notices appeared in THE LANCET of Jan. 30th, and Feb. 13th, respectively.

Hosted by Google

the severity of the constitutional infection, and the very serious extent and nature of the inefficiency to which it gives rise.

Passing on to the appendices to the report we come to that on the progress of hygiene for the year 1896, by Surgeon-Colonel J. L. Notter, the Professor of Military Hygiene at the Army Medical School, Netley, which summarises and reviews the chief points of hygiene that have attracted attention during the past year. The information contained in these articles is considerable and must obviously be valuable and very useful to medical officers. All kinds of subjects bearing on sanitation are touched upon, and under the head of special points of hygiene Ehrlich's test and the so-called serum diagnosis for enteric fever are briefly described.

Under the head of a list of operations performed at the Royal Victoria Hospital, Netley, during 1896 we find an epitome of the surgery at that institution, with some excellent comments and remarks on the cases from the Professor of Military Surgery and the late assistant professor at Netley. The cases of abscess of the liver are well worth reading—indeed, the whole report is instructive. The highly important and successful case of ligature of the common iliac artery by laparotomy for diffuse aneurysm of the external iliac and common femoral vessels, the details of which were published in THE LANCET of Jan. 25th, 1896, is alluded to, together with that of a death from chloroform published in THE LANCET of Sept. 26th, 1896.

The report on the Ashanti Expedition, 1895-96, by Surgeon-Major-General W. Taylor, M.D., late Principal Medical Officer of the expedition, strikes us as uncommonly good. The material is well arranged, the description and remarks are to the point, lucidly expressed, and of an eminently practical character. Surgeon-Major-General Taylor begins his report by saying that the experience gained in the Ashanti Expedition of 1874 was of the greatest assistance in planning the medical part of the present one, and rendered it comparatively easy to decide on what lines the arrangements should be made in view of the prevention and treatment of disease. He lays down in general terms what were the preventive measures followed; they were, in our opinion, wise and good, and, what is more, they were eminently successful. As regards the selection of men we quite concur in thinking that men who have been previously exposed to and suffered from malarious disease should not be sent on such an expedition. Touching clothing, he remarks that drill is neither as cool nor as warm as serge; putties, such as worn in India, are, without doubt, more comfortable and suitable than leggings or gaiters. With regard to the issue of a spirit ration, his remarks are very judicious and sensible; used, as everything else containing a potency for good or evil must be, with care and discretion it is good. The Pasteur Chamberland filters sent out to the expedition were not a success. Their construction was defective and they did not deliver more than an average of five or six gallons in the field. Ice was found of the very greatest service for hospital use. Quinine was issued prophylactically, but, like Surgeon-General Sir A. D. Home's experience in the last expedition, was not found to be of much, if any, good; officers and men who had taken the drug for weeks (as much as 300 grs.) were apparently as liable to fever as those who had not taken any. Arsenic was found to be of service in cutting short ague and remittent fevers. It was given in very bold doses—as much as forty minims or one drachm of liquor arsenicalis were given for a dose without, it is stated, any bad result, provided the precaution were taken of giving a cupful of milk, barley water, or soup immediately beforehand. There are a great many excellent hints and practical observations in the report which may be very usefully read. Not only companies and sections, but individuals, were looked after by officers personally, who saw that each man rubbed himself down and changed into dry underclothing at the end of each march; that he had his tea, cocoa, or soup before starting and immediately on arrival in camp, and that he drank no water that had not been boiled. That the expedition was, from a hygienic and medical point of view, well designed and admirably carried out is the opinion both here and on the Continent.

There is a very good report by Surgeon-Captain H. N. Thompson on the cholera camp at Kokrail, Lucknow, from July 31st to Aug. 27th, 1894. It will be remembered that the severe outbreak was traced to the use of Macnamara's filters. Surgeon-Captain Thompson says that the weak link in the chain of evidence for the truth of the filter theory is that the epidemic decreased immediately after the water-supply was changed, even though it was still passed through the filters, and it also decreased simultaneously in the neighbouring city and district. If the filters were breeding the microbes why did they not, he asks, continue to do so?

Dr. A. E. Wright, the Professor of Pathology at Netley, has an elaborate and well-reasoned paper on the Pathology and Therapeutics of Scurvy, in which he works out the view that all the symptoms of scurvy are perfectly consistent with the theory that the disease consists essentially in an acid intoxication. The article is an acutely and exhaustively reasoned one and will repay careful perusal.

BUBONIC PLAGUE IN INDIA.

WE are glad to begin our report and chronicle this week by the statement that there is at length, according to telegraphic intelligence from Bombay of the 23rd inst., sign of improvement in the epidemic, the mortality tables for Bombay during the preceding six days showing a distinct decrease as compared with the past few weeks.

According to the official returns telegraphed to the Secretary of State for India, in continuation of those already published, it appears that the deaths from all causes in Bombay city for the week ending Feb. 19th were 1772 and the reported deaths from plague 843. The disease continues to show greatest activity in northern portions of the city. Two new hospitals are being prepared. Poona city returns show no increase; one indigenous case occurred in the cantonment during the week. In Coorla, Bandora, Bhiwandi, and the rest of the Thana district the cases have somewhat increased in numbers, but the disease has not spread to fresh places. In Karachi the deaths from plague for the week ending Feb. 19th have been 235; the disease has shown a slight tendency to spread, but it is diminishing in those quarters where it was formerly worst, except in the poorest Mahommedan quarters. Six indigenous cases have occurred in Sind, outside Karachi. Notwithstanding the free egress of the population which has taken place from Bombay in the past and that some of the fugitives have carried the disease with them, so that cases have occurred as far to the south as Bangalore and Belgaum and northward as far as Delhi, the disease has not acquired any firm foothold in the country. Up to the present there have been no cases in Calcutta and the plague has not succeeded in effecting any lodgment in Upper India. Under the Epidemic Diseases Act local officers have full powers of action, and the efforts to deal with the disease generally, to prevent or limit its spread, and to evacuate and improve the sanitation of infected towns and places have been of the most radical, strenuous, and energetic kind and are being systematically carried out. One Indian paper, the *Bombay Gazette*, we may parenthetically remark, has entered a strong protest against the sensational telegrams that have been sent to, and published in, this country, giving rise to an unnecessary amount of alarm both here and on the Continent. There is, no doubt, a natural tendency during times of more or less panic to exaggerate and to "pile up" the figures and details. Be this as it may, the effect of the prevailing epidemic on the material interests of Bombay has been very considerable; but we hope that the worst is now over, and we may also hope and believe that it has not been without some compensatory advantages in that the epidemic has compelled attention to the sanitary state of the city and has led to improvements in this direction not only in Bombay but in many of the other cities and large towns of India.

Dr. Yersin of the Pasteur Institute, whose scientific and bacteriological work in connexion with the plague in China is well known, has left for Bombay, and we may soon expect to hear of the employment of his anti-plague serum in that town and elsewhere in India. Meanwhile Professor Haffkine has been preparing and using in India a prophylactic lymph. Rogers Pasha, the Director-in-Chief of the Egyptian Sanitary Department, has arrived in India, and has been interviewed by one of the staff of the *Times of India*. It appears that in many respects Bombay does not compare at all unfavourably with Cairo and other towns of Egypt as regards sanitation.

THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE NATURE OF THE CANCER CELL.

MR. HAROLD J. STILES, F.R.C.S. Edin., who has been engaged for some time in researches on the origin of the cancer cell, discussed that question in a lecture before the Royal College of Surgeons of Edinburgh on the 19th inst He confined his lecture to a consideration of the origin and nature of the more important of the structures which have been described as parasites in cancer. He did not propose to discuss the wider question as to whether or not cancer was a parasitic disease. During the lecture a large series of micro-photographs from the lecturer's own preparations were shown upon the screen. The appearances presented by the various stages of development of the coccidium oviforme of the rabbit were first shown in order that they might be compared with the cancer bodies subsequently shown. The photographs illustrative of Paget's disease of the nipple showed that the peculiar cell elements found in that affection were not psorosperms, but epithelial cells which had undergone a malignant metaplasia, thus confirming the observations of Karg and others. Passing to the ordinary squamous epitheliomata, the lecturer first discussed the nature and formation of the "cell nests," and pointed out that the majority of the structures which had been referred to in these tumours as parasites owed their origin to what Unna terms a hyaline degeneration of the epithelial cells. This degeneration furnishes the chief source of the fuchsin bodies of Russell and of the psorosperms of Darier and Wickham. Typical examples of the "amœbæ" of Korotneff and Kurloff were shown and demonstrated to be due to the hyaline degeneration affecting certain of the systems of protoplasmic fibrils, which, as Kromayer has shown, unite together the prickle cells of the epidermis. The methods of Unna were advocated as particularly valuable for demonstrating the various morphological forms presented by cells undergoing hyaline degeneration. The greater part of the lecture was devoted to the so-called parasites in glandular cancers. Mr. Stiles found most difficulty in tracing the origin of the bodies which had been singled out as parasites, more especially by Ruffer. The lecturer had never been able to satisfy himself that typical Ruffer's bodies occurred in the ordinary skin cancers, although he had no difficulty in demonstrating them in cancers of glandular origin. He referred to the great delicacy of these bodies, and pointed out how much their satisfactory demonstration and correct interpretation depended upon the employment of good microscopic technique. Mr. Stiles had got the best results by making films of scrapings taken from perfectly fresh tumours and treating them according to the principle recommended by Dr. Robert Muir for studying histological changes in the blood. The films are placed at once in the fixing solution, and at no time during the staining or mounting are they to be allowed to dry. This method has the further advantage of doing away with the heat and shrinking attendant upon section cutting by the paraffin method. Photographs were demonstrated to show that the larger forms of Ruffer's bodies were produced by the degeneration of an invaginated cell. Some of the medium-sized forms result from the degeneration of the nucleus of a uninucleated or multinucleated cell. The smaller forms, single and multiple, resulted, in the lecturer's opinion, from degeneration occurring in connexion with a fragmented nucleus, as well as in connexion with fragments of chromatin, or parachromatin, which had become detached from the nucleus. Mr. Stiles was inclined to agree with Pianese, that still other forms were derived from limited degenerations of the cell protoplasm, and possibly also from perversions of cell secretions which had accumulated within the cell. In referring to the work upon pathogenic blastomycetes (yeasts) done within the last two years by Italian observers the lecturer pointed out that while the blastomycetes had a certain morphological resemblance to the appearances already noted, no proof whatever had been adduced to show that they were causally present in cancer, or that they could give rise to the cancerous process when inoculated into animals. At the conclusion of his lecture Mr. Stiles said he wished to direct attention to the recent and valuable histological researches of Pianese upon the pathology of the cancer cell. So far as he had been able to confirm this writer's observations, he agreed with him that all the so-called parasites which had up to the present been described as occurring in cancers were susceptible of explanation as degenerations of one or all of the constituents of tumour-cells or as metamorphoses of their secretion.

At the close of the lecture Mr. Stiles was highly complimented by the President of the College, Emeritus Professor Struthers, on the value of his work towards the elucidation of the important question to which the lecture related. The President announced that the next lecture of the series would be delivered by Mr. Caird.

THE BATTLE OF THE CLUBS.

A SCHEME FOR THE ESTABLISHMENT OF PROVIDENT MEDICAL ASSOCIATIONS.

DR. FREDERICK PEARSE, honorary secretary of the Portsmouth Medical Union, has sent us the draft of a scheme for the universal establishment by medical men of medical clubs throughout the country. Under the working of his scheme he considers that the sick poor would obtain adequate medical treatment, while the evils rampant under the lay management of certain associations would disappear.

There is undoubtedly, as he points out, a large number of the struggling working classes in which the weekly payment of subscriptions to a medical benefit is the only method by which the medical man gets paid at all. A certain class of these people are not to be trusted for the private account of even a few shillings. The provident scheme is, therefore, favourable to the profession. His scheme aims at giving the poor the advantages of private patients while being sufficiently comprehensive to provide for the medical relief of all the classes between those who are in receipt of parochial relief and those who are just able to pay the lowest private fees.

Medical Men must Unite.

It is necessary, runs the draft, for each section of the profession, be it in town or country, to show a united front. Medical men in every town and district should combine and establish a Provident Medical Association with the object of controlling the administration of medical relief to the working classes. Such an association may be stated to have for its object:—"To provide medical advice and physic for the working classes according to a sliding scale and adjusted to their means with the advantage of a selection of their medical attendant."

The acting medical officers should be the executive body with the support of any or all other practitioners as honorary staff and members of a general committee or council. Private medical clubs and medical aid associations must be given up before joining the staff of this mutually benefiting organisation. Powers must be given to the staff to deal with members of their body guilty of unprofessional conduct.

Scale of Payment.

The following graduated tariff seems to Dr. Pearse just:—

	Each member at the rate of
Single members—	
Earning 20*s.* a week and under	4*s.* per annum.
Earning from 20*s.* to 30*s.* a week	5*s.* per annum.
Married members—	
Earnings of family 20*s.* a week and under ... Family tickets at the rate of 20*s.* per annum.	4*s.* per annum.
Earnings of family from 20*s.* to 30*s.* a week ... Family tickets at the rate of 30*s.* per annum.	5*s.* per annum.
Earnings of family from 30*s.* to 40*s.* a week ... Family tickets at the rate of 42*s.* per annum.	6*s.* per annum.

Single persons earning over 30*s.* a week and married persons where the income of the family exceeds 40*s.* a week should not be admitted; while persons renting houses over £20 a year will be assumed to be earning over £2 a week. The subscription could be paid weekly or monthly, but the services of a collector would have to be used, only under rigid instructions that he was not to canvass.

A Few Important Points.

Candidates for membership would be, of course, examined, and invalid or unsound lives are accepted at special rates.

An option is given to benefiting members to select their own medical attendant—a privilege which has been almost denied to the poor.

To obviate useless calls, except in cases of sudden urgency, some extra charge should be demanded for special visits. Probably the sum of 1*s.* would be suitable to all parties. Members of the acting staff might coöperate "with one another" in cases requiring additional assistance at the following rates:—Consultation Fees, 10*s.* 6*d.*; Administration of Chloroform, &c., 10*s.* 6*d.*; Assistance at Midwifery Case or at Operation, 10*s.* 6*d.*

The expenses of such an association would be reduced to a minimum. No particular building is required, as the patients go to the surgeries of the medical officers. Printing, stationery, and salary of clerk are alone taken out of the Doctor's Fund.

We commend Dr. Pearse's scheme to our readers, especially in districts where the tyranny of the lay managers of

Hosted by Google

certain clubs has begun to make itself felt. If the profession unites in its demand for fair treatment the profession must win. And no one save those who are blinded by self-interest can fail to see that a wage limit must be imposed or the medical profession will be, as it is, cruelly exploited.

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia of the Fellows of the Royal College of Physicians of London was held on the 23rd inst., Dr. WILKS, F.R.S, President, being in the chair.

A communication was read from Sir F. Bateman containing a memorial from medical practitioners of Norfolk asking the College to consider the question whether it was right for the College to countenance medical officers of aid associations in consultations. It appears that the Norwich Medical Institute, having some 10,000 members, employs two salaried medical officers, and until recently two consultants, who have resigned their offices. This institute has accumulated large funds; the members' annual subscription is 3*s*., which entitles them when ill to the services of the medical officers. At a meeting of the medical profession in Norwich there was a unanimous opinion that it was unbecoming of any medical man to take office in such an institution, and the College was asked for its opinion as to the propriety of physicians meeting in consultation any such medical officers.—On the motion of Sir W. Priestley, M.P., seconded by Dr. Cullingworth, the memorial was referred to the Council for consideration.

A somewhat similar communication was read from the Portsmouth Medical Union complaining of Licentiates of the College, who belonged to aid societies or who had their own private clubs, "touting" for patients.—This was referred to the Censors' Board on the motion of Dr. Dickinson, seconded by Dr. F. T. Roberts.

Letters were read from Dr. Rentoul and from the Midwives Bill Committee, the one inviting opposition to, and the other seeking approval of, the Bill now before Parliament.

A report was presented from the delegates of the Royal Colleges on the question of a Teaching University of London, and after a lucid description of the situation by Dr. Allchin, who moved the adoption of the report, which was seconded by Dr. Norman Moore, the report was unanimously agreed to. It embodied the following resolution:—

"That the Royal College of Physicians of London and the Royal College of Surgeons of England, in full accord with their previous action, express the earnest desire that Her Majesty's Government will at the earliest opportunity re-introduce a Bill for the reconstitution of the London University by Statutory Commission on the general lines of the Report of the Cowper Commission, and do assure the Government that such a course will have their approval and support."

It was also resolved that copies of this resolution should be forwarded forthwith to the Lord President of the Council, the Right Hon. A. J. Balfour, and the Senate of the University of London.

The President explained the steps that had been taken at a meeting of Presidents of scientific societies, convened by the President and Council of the Royal Society to further a scheme for the promotion of science in commemoration of the sixtieth year of Her Majesty's reign, by the establishment of a fund to be called "The Victoria Research Fund," to be administered by representatives of the various scientific societies, for the encouragement of research in all branches of science. It was resolved that the College do concur in the scheme and that the President be requested to act on behalf of the College in the matter.

On the motion of Sir Dyce Duckworth, seconded by Sir W. Priestley, M P., it was resolved:—

"That a committee be appointed to advise the College on the desirability of making a formal declaration of opinion to the Government in favour of the re-enactment of the Contagious Diseases Acts in India, or of some such modification of them as may prevent the spread of contagious diseases."

The President nominated the following Fellows to serve on the committee: Sir Dyce Duckworth, Dr. Church, Dr. Payne, Sir J. Ewart, Sir W. Roberts, Dr. Bowles, Dr. Barlow, and Dr. J. Anderson, C I.E.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Sunderland Urban Sanitary District.—Dr. H. Scurfield, the medical officer of health of Sunderland, has recently furnished an interesting report on the methods of excrement disposal in his district, and he supplies at the same time some useful information with regard to excrement disposal in the principal towns of the kingdom, together with the general, enteric, and diarrhœa death-rates in the respective towns. In one table is furnished a list of towns in which the number of privy middens exceeds or approximates "5 per cent. of the population," and in another a list of what are termed "watercloset towns." From the average rates for 1890–95 in the respective tables it is to be learnt that in the privy midden towns the general, fever, and diarrhœa rates amount to 20·7, 0·26, and 1·08 per 1000, as against rates of 18 3, 0·15, and 0·52 for the watercloset towns. In the latter group is to be noted the high enteric fever death-rates for Dublin and Liverpool, but in the former instance Sir Charles Cameron regards the saturation of the soil by the privy middens, which until recently obtained, as a powerful factor in the maintenance of the disease in Dublin; and in the latter case the enormous density of population which prevailed in what was formerly the urban sanitary district of Liverpool (prior to the borough extension) had, Dr. Scurfield thinks, an important bearing upon the rates. The whole town-rates are, as Dr. Scurfield doubtless recognised, open to certain fallacies, and he has therefore supplied in his report other tables showing for certain large towns the incidence of enteric fever in houses served with privy middens as compared with those served by water-closets. Amongst these tables may be mentioned those relating to Birmingham, Leicester, and Middlesborough. The figures relative to the latter town we furnished recently in our columns when reviewing Dr. Bruce Low's report on that town. There are in Sunderland some 10 351 privies and ashpits and the annual death-rates from "fever" for that town during 1890–95 amounted to 0·62 per 1000—a rate which is very greatly in excess of other privy-midden towns with the solitary exception of Widnes, which has a similar rate, and it is interesting to note that the privy middens of Widnes have recently been strongly condemned by Dr. Bruce Low. Altogether Dr. Scurfield makes out a very strong case against the privy-midden system, and it is much to be hoped he has succeeded in persuading the sanitary authority of Sunderland to adopt the water-carriage system. The privy middens in his district cover, he points out, some ten acres, and the contents are continually soaking into the ground, the result being that the soil is becoming more and more sewage-logged every year.

Stockport Sanitary District.—In his annual report for 1895 Dr. Charles Porter states that the Sanitary Committee of the Stockport council has called the attention of the guardians to the large number of children unprotected by vaccination; the guardians in their turn have called upon the vaccination officer for an explanation. We wonder if the guardians have in the past prosecuted defaulters according to law. In connexion with autumnal diarrhœa Dr. Porter has continued his observations on the relation of this disease to the temperature of the earth at four feet, and his results, which now extend over four years, fully endorse the discoveries of the late Dr. Ballard. Referring to the subject of "return" cases of scarlet fever, Dr. Porter aptly remarks "that if sanitary authorities are to continue to isolate scarlet fever patients in public hospitals it is absolutely essential that the public should be made to understand that, despite the exercise of every care, it is as wholly impossible to guarantee freedom from infection on discharge as it is to guarantee freedom from death whilst under treatment." Dr. Porter appears to have very kindly undertaken to conduct six patients, who had been bitten by a rabid dog, to Paris for treatment at the Pasteur Institute. Although this is not one of the duties of medical officers of health as laid down by the Local Government Board, it is no doubt an action of which that Board would highly approve. Dr. Porter is not the only medical officer of health who has been good enough to personally conduct patients to Paris

Hosted by Google

and it may be useful to other sanitary authorities if we state that the inclusive cost of sending these six patients with the medical officer of health to Paris was but £73 1*s.* 6*d.*

Aston Manor Urban District.—Mr. Henry May, in his annual report for 1896—which, by the way, is the first printed report for that year we have received—draws attention to the extent to which inefficient vaccination prevails in his district, many "vaccinated" children presenting, he tells us, but one small cicatrix. It would surely be better for the cause of vaccination if medical men who thus bring children within the ranks of the "vaccinated" were to refuse to perform the operation unless they are allowed to procure proper protection. Mr. May points out that although the only efficient manner of controlling small-pox is by vaccination and re-vaccination, it will be necessary in Aston, owing to the neglect of this precaution, to do what can be done to increase the isolation accommodation for small-pox, and the sanitary authority have, it appears, procured a site remote from habitations for the erection of a small-pox hospital. Diphtheria during 1896 showed a very marked increase in Aston Manor; in fact, it appears to have shown a similar behaviour in this respect as in Birmingham, upon which district it abuts. An attempt was made in 1896, possibly on account of the success of a somewhat similar case in Birmingham, to obtain damages from the district council owing to the occurrence of a "return" case of scarlet fever. The council, however, refused to recognise any responsibility and instructed their clerk to defend any action which might be brought. No more was heard of the case.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6715 births and 3970 deaths were registered during the week ending Feb. 20th. The annual rate of mortality in these towns, which had been 20·8 and 19·6 per 1000 in the two preceding weeks, further declined last week to 18·8. In London the rate was 17·8 per 1000, while it averaged 19·5 in the thirty-two provincial towns. The lowest rates in these towns were 13·7 in West Ham, 14·2 in Brighton, 14·9 in Huddersfield, and 15·1 in Portsmouth; the highest rates were 23·2 in Salford, 23·8 in Liverpool, 25·1 in Burnley, and 25·8 in Preston. The 3970 deaths included 316 which were referred to the principal zymotic diseases, against 361 and 337 in the two preceding weeks; of these, 94 resulted from whooping-cough, 59 from diphtheria, 55 from measles, 45 from diarrhœa, 40 from scarlet fever, 22 from "fever" (principally enteric), and 1 from small-pox. No death from any of these diseases was recorded last week either in Birkenhead or in Halifax; in the other towns they caused the lowest death-rates in Sunderland, Swansea, and Derby, and the highest rates in Gateshead, Plymouth, Bolton, and Salford. The greatest mortality from measles occurred in Salford, Gateshead, Bradford, Bolton, and Plymouth; and from whooping-cough in Salford, Huddersfield, Gateshead, Bristol, Blackburn, and Burnley. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 59 deaths from diphtheria included 40 in London, 2 in West Ham, 2 in Cardiff, and 2 in Birmingham. One fatal case of small-pox was registered in London, but not one in any other of the thirty-three large towns. There were 34 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 20th inst., against 9, 21, and 38 at the end of the three preceding weeks; 3 new cases were admitted during the week, against 7, 12, and 20 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2901, against 3311, 3153, and 3050 on the three preceding Saturdays; 227 new cases were admitted during the week, against 254, 245, and 226 in the three preceding weeks. The deaths from diseases of the respiratory organs in London, which had been 404 and 373 in the two preceding weeks, further declined to 335 last week, and were 149 below the corrected average. The causes of 54, or 1·4 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bradford, Leeds, Sheffield, Newcastle-upon-Tyne, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Norwich, Preston, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 24·3 to 28·8 per 1000, declined again to 25·5 during the week ending Feb. 20th, but was 6·7 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 19·9 in Edinburgh and 21·7 in Dundee, to 29·4 in Glasgow and 30·7 in Perth. The 761 deaths in these towns included 45 which were referred to whooping-cough, 42 to measles, 22 to diarrhœa, 4 to scarlet fever, 4 to "fever," and 2 to diphtheria; in all, 119 deaths resulted from these principal zymotic diseases, against 96 and 105 in the two preceding weeks. These 119 deaths were equal to an annual rate of 4·0 per 1000, which exceeded by 2·5 per 1000 the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had increased in the four preceding weeks from 26 to 39, further rose to 45 last week, and included 33 in Glasgow, 8 in Edinburgh, and 3 in Perth. The deaths referred to measles, which had been 28 and 31 in the two preceding weeks, further increased to 42 last week, of which 38 occurred in Glasgow and and 2 in Aberdeen. The 4 fatal cases of scarlet fever showed a slight further decline from the numbers recorded in recent weeks, and included 2 in Glasgow. The deaths referred to different forms of "fever," which had been 4 and 7 in the two preceding weeks, declined again to 4 last week, of which 3 occurred in Glasgow. The deaths from diseases of the respiratory organs in these towns, which had been 229 and 240 in the two preceding weeks, declined to 218 last week, but exceeded by 113 the number in the corresponding period of last year. The causes of 37, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 44·2 and 41·2 per 1000 in the two preceding weeks, rose again to 43·4 during the week ending Feb. 20th. During the past seven weeks of the current quarter the death-rate in the city has averaged 40·7 per 1000, the rate during the same period being 18·8 in London and 22·1 in Edinburgh. The 291 deaths registered in Dublin during the week under notice showed an increase of 15 upon the number in the preceding week, and included 72 which were referred to the principal zymotic diseases, against 52 and 58 in the two preceding weeks; of these, 43 resulted from measles, 16 from whooping-cough, 5 from scarlet fever, 5 from "fever," 2 from diarrhœa, and 1 from diphtheria. These 72 deaths were equal to an annual rate of 10·7 per 1000, the zymotic death-rate during the same period being 1·4 in London and 2·3 in Edinburgh. The fatal cases of measles, which had increased from 7 to 26 in the three preceding weeks, further rose to 43 last week. The deaths referred to measles, which had been 24 and 25 in the two preceding weeks, declined to 16 last week. The 5 fatal cases of scarlet fever exceeded by 3 the number in the preceding week, and the 5 deaths referred to "fever" exceeded those recorded in any recent week. The 291 deaths registered in Dublin last week included 59 of infants under one year of age, and 48 of persons aged upwards of sixty years; the deaths of infants showed an increase, while those of elderly persons were below those recorded in any recent week. Three inquest cases and 6 deaths from violence were registered; and 83, or more than a fourth, occurred in public institutions. The causes of 29, or nearly 10 per cent., of the deaths in the city last week were not certified.

THE *Glasgow University Magazine* states that the Students' Representative Council have passed, among others, the following recommendation: "That a petition be sent to the Senate begging them to request the University Court to make such arrangements with the managers and directors of the Western Infirmary as will enable the Professor of Materia Medica and Therapeutics to teach, not only theoretically, but also clinically, so important a branch of medical science as therapeutics."

THE SERVICES.

ARMY MEDICAL STAFF.

SURGEON-MAJOR R. H. S. SAWYER has been ordered to Dublin for duty. Surgeon-Captain E. Eckersley embarks for service on the West Coast of Africa. Surgeon-Major D. O'Sullivan has embarked in the transport *Dunera* for Bombay.

Brigade-Surgeon-Lieutenant-Colonel Edmond Townsend, M.D., to be Surgeon-Colonel, vice M. Cogan, retired. The under-mentioned Surgeon-Lieutenant-Colonels retire on retired pay:—H. J. Robbins, M.D., Isaac Boulger, Thomas Boyd, Joseph J. Lamprey, Phineas B. Tuthill, M.D., F.R.C.S. Irel., and John P. Hunt, M.D., F.R.C.S. Irel. The surname of Surgeon-Lieutenant L. Addams-Williams is as now and not as stated in the *Gazette* of Feb. 16th, 1897.—*London Gazette.*

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Captain F. Wyville-Thomson, Bengal Establishment, is appointed to be Medical Officer, Lawrence Military Asylum, Sanawar, vice Surgeon-Captain C. H. Bedford. Surgeon-Major W. F. A. Street, D.S.O., and Surgeon-Captain A. J. Heath, have respectively delivered over and received charge of the office of Deputy Sanitary Commissioner, Central Registration District. Surgeon-Captain A. E. Smithson, A.M.S., is appointed to the Civil Medical Charge of Ranikhet, in addition to his military duties. Surgeon-Captain S. B. Smith, Bengal Establishment, whose services have been placed temporarily at the disposal of the Chief Commissioner, Central Provinces, by the Government of India, Home Department, is posted to the Jubbulpore District on special famine duty. Surgeon-Lieutenant C. Thomson, Bengal Establishment, whose services have been temporarily placed at the disposal of the Chief Commissioner of India, Home Department, is posted to the Sangor District on special famine duty.

The Queen has approved of the following admissions to the Indian Medical Services:—To be Surgeon-Lieutenants: Andrew Augustine Frayne McArdle, Jasper Maxwell Woolley, Clayton Arbuthnot Lane, Thomas Bernard Kelly, James Henry Hugo, William Hamilton Kenrick, Charles Henry Watson, Charles Hope Septimus Lincoln, Raymond Herbert Price, Edgar Francis Eardley Baines, Geoffrey Orr Fern Sealy, and Reginald Bryson.—*London Gazette.*

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Staff Surgeon: John Jenkins to the *Calliope*. Surgeons: Sidney Croneen to the Royal Marine Depôt, Walmer; Rowland A. Kirby to the *Victory*, additional; Alfred H. L. Cox to the *Alecto;* and Frederick J. Burns, M.D., to the *Wildfire.*

The following Surgeons have been promoted to the rank of Staff Surgeons in Her Majesty's Fleet:—Henry Erskine South, Alfred Matthew Page, Alfred Cropley, John Jenkins, Horace Elliott, Ernest Denman Minter, and Robert Forbes Bowie.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major E. Shedd to be Surgeon-Lieutenant-Colonel. Surgeon-Captain H. H. Smith, having resigned his appointment in the Volunteers, ceases to be an officer of the Army Medical Reserve.

VOLUNTEER CORPS.

Rifle: 8th Volunteer Battalion the Royal Scots (Lothian Regiment): Ronald Cadell Macdonald, M.B., to be Surgeon-Lieutenant. 1st Volunteer Battalion the Prince Albert's (Somersetshire Light Infantry): Surgeon-Lieutenant F. Lace to be Surgeon-Captain. 4th Volunteer Battalion the Cheshire Regiment: Eugene Charles McCarthy, M.B., to be Surgeon-Lieutenant. 1st Wiltshire: Herbert Lorraine Earle Wilks, gent., to be Surgeon-Lieutenant. 4th (Stirlingshire) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): John Gilfillan Ronald, M.B., to be Surgeon-Lieutenant. 8th Middlesex: Edmund Ultain Frederick MacWilliam Bourke, gent., to be Surgeon-Lieutenant. 1st Tower Hamlets: Surgeon-Lieutenant J. P. Simpson, M.D., to be Surgeon-Captain.

VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies:—Quartermaster William Kidston resigns his commission.

THE SERVICE EXAMINATIONS.

The following is a list of successful candidates for commissions in the Army Medical Staff and Indian Medical Service at the recent examinations in London:—

ARMY MEDICAL STAFF.

Name.	Marks.	Name.	Marks.
S. L. Cummins	2272	J. G. Walker	2005
C. H. Hopkins	2207	H. G. F. Stallard	1948
J. McArdle	2159	Q. D. Jephson	1887
P. Mackessack	2158	H. L. W. Norrington ...	1876
L. J. C. Hearn	2143	J. Poe	1847
J. McD. McCarthy	2065	J. Crean	1828
E. Brodribb	2055	R. W. N. Bowen	1809

INDIAN MEDICAL SERVICE.

Name.	Marks.	Name.	Marks.
F. G. P. Murray	2823	J. A. Dredge	2574
S. Anderson	2814	R. W. Knox...	2530
F. H. G. Hutchinson ...	2646	R. Fenton	2506
J. L. Marjoribanks	2603		

THE MILITARY WORKS BILL.

We are very glad that the system upon which the House set its seal in 1890 to replace barracks which were worn out or insanitary by barracks fit for the habitation of troops is to be continued. With reference to the provision of barracks it was, said Mr. Brodrick, impossible to over-rate the importance of the proposals of the Government. It was a scandal to see that the huts erected at Aldershot, the Curragh, and other places had been allowed to continue so long. They were in an insanitary condition and, he was afraid, not free from vermin. He was glad that they were about to make provision for better quarters for their soldiers generally, and especially for the married soldiers. The work that has either been already completed or is going on at our home and foreign stations is very considerable, and includes barrack or hospital accommodation at Bermuda, Gibraltar, Halifax, Malta, the Cape, Mauritius, and Hong-Kong abroad, and at a great many of our large camps and stations in this country.

PROFESSOR DELORME.

Among contemporaneous military surgeons few names are better known than that of Médecin-Principal Edmond Delorme, who so ably occupies the chair of Clinical Surgery in the Val-de-Grâce School. At a recent election to fill a vacancy in the Académie de Médicine this distinguished officer obtained 70 votes out of a possible 74, a fact which affords conclusive proof not only of his professional merit but also of his personal popularity. Born at Lunéville in 1847 Dr. Delorme entered the army in 1866 and has served continuously ever since. In 1871 he took his M.D. degree at the Faculty of Paris, and six years later competed successfully for admission into the professorial fold. In addition to carrying off a great number of the prizes offered by the Académie de Médecine and the Institut de France, he is likewise a frequent contributor to periodical literature; but the work by which he is best known to fame in his History of French Military Surgery, published in two volumes by Alcan.

THE BENIN EXPEDITION.

We always seem to have some small war or other on hand. A punitive expedition to Benin after what had taken place was, of course, required, and it has been most successfully carried out with a relatively small loss of life. We much regret to notice the name of Surgeon C. J. Fyfe, R.N., of the *St. George* among the killed. With the capture of Benin we do not appear to have succeeded in capturing the king of that place; but let us hope that there will henceforth be an end of the fetich sacrifices and human massacres of which our sailors had such gruesome evidences on entering Benin.

DEATHS IN THE SERVICES.

Surgeon-Major E. R. Power, A.M.S., aged forty-two years. He was appointed Surgeon in 1878, and was promoted to the rank of Surgeon-Major in 1890. For his services in the Egyptian War of 1882 he obtained the Medal and Khedive's Star. He also held the Soudan Clasp of 1885 for the Soudan Campaign, in which he also served.

At a meeting of the Service Member's Committee of the House of Commons last week the Contagious Diseases Acts and other important matters were discussed.

Her Majesty has conferred the Distinguished Service Order upon Surgeon-Major G. D. Hunter, A.M.S., for services with the Egyptian Army.

Surgeon-Colonel Ross, Inspector General of Civil Hospitals, Bengal, has been granted eight months' furlough.

"Audi alteram partem."

THE MIDWIVES REGISTRATION BILL.

To the Editors of THE LANCET.

SIRS,—I shall be glad to be allowed to explain to the profession one or two points in reference to the Bill which appear to have been somewhat misunderstood. First, with regard to the omission of the words "natural labour," you have so fully recognised this as an improvement on previous Bills that I need not occupy your space with the reasons that weighed with the committee in making the alteration further than by saying that it was guided very much by the considerations to which you call attention and also by the conviction that Parliament is not the most suitable place for discussing what is and what is not "natural labour." Such a duty seems more appropriately assigned to the Midwives Board. The same considerations led the committee to avoid any attempt to lay down precise rules for regulating the education, examination, and discipline of midwives. The duty of formulating these rules is that for which the Board is specially called into existence. Details of this kind are out of place in an Act of Parliament.

With regard to Dr. Rentoul's point as to the absence under the Bill of power on the part of the General Medical Council "to take any part in arranging the plan for the education of intending midwives," there is no disposition on the part of the framers of the Bill to restrict the powers of the General Medical Council; indeed, the Board is under its general superintendence (Clause 5, i.). It is distinctly stipulated that all the rules and regulations for the practice of midwives must be "approved" by the General Medical Council, and if the General Medical Council does not approve of any of the regulations or of the general policy of the Midwives Board it can withhold consent to its action until it does approve or until the Privy Council has decided the matter. If the addition of the words "or otherwise" would make this still clearer by all means let them be inserted.

Two other points remain to be considered—namely, the constitution of the Board and the appointment of a local supervising authority. With regard to the former I can scarcely think, in the light of recent events, that Dr. Rentoul's plea for the direct representation of the medical profession on the Midwives Board is likely to meet with general support. The appointments are surely better left in the hands of responsible bodies such as those named in the Bill. Dr. Rentoul has omitted to notice that the six persons to be appointed by the Lord President of the Council need not be medical practitioners and need not even be all of the same sex. These six persons represent the public and are to safeguard its interests. Without them the Board would be too exclusively professional. Lastly, with respect to the appointment of the medical officer of health as the local supervising authority the precise wording is as follows: "Every local sanitary authority ..... shall appoint its medical officer of health or other registered medical practitioner or practitioners as the local supervising authority over midwives in the sanitary district." If, therefore, the medical officer of health does not care for the remuneration or for the work he need not be appointed. As a rule, however, he will probably be found to be the most suitable person, especially as he has offices and staff at command. Dr. Rentoul's amusing remark that "this Bill is, of all its predecessors, the most dangerous" may be left to take care of itself. Surely, however, none of your readers will be influenced by the reiterated assertions which Dr. Rentoul puts forward in the place of arguments. One or two of the statements he makes in his letter I have already taken occasion publicly to deny. They ought not to have been repeated.—I am, Sirs, yours truly,

ROWLAND HUMPHREYS,
Honorary Secretary, Midwives Bill Committee.
Buckingham-street, Strand, W.C., Feb. 22nd, 1897.

To the Editors of THE LANCET.

SIRS,—As there is no evidence that the Parliamentary Bills Committee of the British Medical Association has taken, or is about to take, any action with respect to Mr. Tatton Egerton's Bill for the registration of midwives, at present before the House of Commons, the council of our branch has determined not to share in such apathy and in such utter disregard of the frequently expressed wishes of the Members of the British Medical Association. At a recent meeting of the council of our branch the following resolutions were adopted: "(*a*) The Council of the Lancashire and Cheshire Branch of the British Medical Association disapproves of Mr. Tatton Egerton's Bill for the registration of midwives and will endeavour to prevent its passing into law; (*b*) that five members of the council be, and are now, appointed as a deputation to wait upon the Lancashire and Cheshire members of Parliament urging them to oppose the second reading set down for Feb. 26th or any future date; (*c*) that the members of the deputation be requested to draw up a circular pointing out the objections to the Bill and the reasons for opposing it, such circular to be sent to every member of the House of Commons and the House of Lords. The members of the deputation are Dr. Brierley, Dr. Macfie Campbell, Dr. Gledhill, Dr. Arthur Helme, and Dr. Woodcock. Dr. Helme will also act as secretary to the deputation.—I am, Sirs, yours faithfully,

JAMES BARR,
Honorary Secretary to the Lancashire and Cheshire
Feb. 20th, 1897. Branch of the British Medical Association.

To the Editors of THE LANCET.

SIRS,—Will you allow me, on the near approach of the second reading of the above-named Bill, to say, as one loyal to our profession and at the same time deeply solicitous for "the poor" (in whose interest, the memorandum on the Bill informs us, it is "especially" propounded), that I protest against it, first, as being unstatesmanlike in that it deliberately avoids taking the best and surest guarantees for the well-being of the nation's mothers and for the nation's perpetuation in its preference for cheap and nasty substitutes; and, secondly, as being retrograde in its proposal to lower the standard of medical service, even beneath present Poor-law regulations, by instituting an inferior, incompletely trained body of midwifery practitioners, who shall be foisted, under State sanction and armed with diplomas, upon the poorest and most ignorant of the populace. It would provide, not, indeed, "especially"—as the memorandum falsely pretends—but *only* for the poor, and *only because they are poor*, in their hour of need, when contributing with the fruit of their bodies to the nation's continuance and growth, the attendance of a body of women by intention so imperfectly trained that no single man of the well-to-do promoters or supporters of the Bill would for a moment entrust his own women to their care, nor would the fine society ladies who are so loud in its favour ever dream of leaving their precious selves in such ignorant hands. This consideration ought, I think, by itself to condemn the measure. The truth, of course, is that the life and well-being of all citizens, be they of high or of low degree, rich or poor, are alike the concern of the State, while the claims of humanity are not diminished but increased and intensified by poverty. By all means let us have nurses galore trained for lying-in, as for medical and surgical, cases, but let them be prohibited from undertaking attendance on confinements *except as awaiting the supervision of a qualified practitioner*, who shall be held primarily responsible. For patients too poor to pay let such thoroughly skilled professional service be secured by means of dispensaries, maternity hospitals and clubs, and by freer recourse to the excellent provisions of the Poor-law. Those three forms of existing voluntary agencies should be generally extended, better organised, and, if need be, rate-aided and brought under popular control. Every parish or other suitable district, every church and chapel, might have its maternity club, worked on the same lines as clothing and coal clubs. Under the Poor-law relieving officers and overseers can grant orders available, not only for the Poor-law medical officers, but for any medical man or woman who can be found to respond to the call, and, indeed, in a case of emergency no order at all is requisite, but the guardians can pay the medical man's fee when they are satisfied that the patient is unable to do so. No stigma of pauperism, no disfranchisement, or other social ban attaches to such medical relief. It is the statutory right of the impoverished citizen. Let us, then, throw ourselves into a sane, honest, and truly humane movement to make all the existing machinery more general and effective. Let us, above all—Members of Parliament, medicals, and

Hosted by Google

citizens at large—refrain from doing unto *other men's* wives that which we would not do unto *our own*.

I am, Sirs, yours faithfully,

Lofthouse-place, Leeds, Feb. 23rd, 1897. THOS. M. WATT.

SLOW PULSE AND SYNCOPAL ATTACKS.

To the Editors of THE LANCET.

SIRS,—I would like to express my appreciation of Dr. Ogle's most interesting paper on Some Cases of Unusual and Persistent "Slowness" of Pulse, presumably dependent upon Interference with the Intrinsic Nerves and Ganglia of the Heart in THE LANCET of Jan. 30th. I have considered the subject briefly in one of my recent lectures on Angina Pectoris and Allied States. I was particularly interested in the original description by Stokes and Adams of those cases of slow pulse in which cerebral symptoms developed—what Stokes called false or pseudo-apoplexy. While vertigo and syncope are the two most common associated features, epileptiform attacks may develop, as in two of Dr. Ogle's cases, as well as in those of Dr. St. George Mivart and Dr. Gibbings, to which he refers. They have also been described by Dr. Kinnicutt in a case in which the pulse was between 30 and 40, and during the attacks as low as 13, and once 7.[1] Dr. Jacobi at the same meeting referred to cases with convulsive seizures. In the case of J. W——, given in my lectures, I have recently had a note from his physician stating that Mr. W—— has as many as twenty-five attacks of vertigo and transient losses of consciousness in the day, and that his pulse now is permanently at 30 per minute.

A very interesting feature is the long duration of some of the cases. I saw in October a man, aged seventy-four years, who had been told thirty years ago that he had serious heart trouble and that his pulse was only 50 per minute. It remained slow until two or three years ago. In 1891, following a good deal of effort in preaching, he had an attack of angina pectoris, after which the pulse for three days beat at less than 38 to the minute. When I saw him he had cardiac dyspnœa without the bradycardia; he died suddenly one night. In another case, seen on Dec. 14th, the patient, a man, aged sixty-five years, had a pulse of 40 per minute. He had had two attacks of prolonged unconsciousness, one in June, 1895, after which he felt a good deal dazed, and the other in June, 1896, when he was unconscious for twenty minutes.

Huchard's discussion of this syndrome, or, as he calls it, "maladie Stokes-Adams," is most interesting and deserves more attention than it has received from English writers. I do not know the source of the statement made in my text-book (to which Dr. Ogle refers) as to Napoleon's epilepsy. Part at least of the vocation of an author of a work of that kind is "endless imitation," though I have tried in many points to go to original sources. Those acquainted with Archbishop Whately's famous pamphlet, "Historic Doubts Relative to Napoleon Bonaparte," will feel thankful to Dr. Ogle that he has left two at least of the three interesting medical features in the history of that great man.

I am, Sirs, very truly yours,

Feb. 12th, 1897. WILLIAM OSLER.

P.S.—It is possible that Colonel Townshend's case belongs to this remarkable group ("English Malady," second edition, p. 307). The disappearance of the pulse was associated with syncope. Colonel Townshend's statement, as given by Dr. Cheyne, was that "he could die or expire when he pleased, and yet by an effort or somehow he could come to life again, which it seems he had sometimes tried before he had sent for us." The physicians in attendance were very unwilling that he should make the trial in his weak state, but he insisted. His pulse became more and more feeble until it disappeared. He remained pulseless and breathless for about half an hour, and then he began to breathe quietly and speak softly. This was at 9 A.M., and he died at five o'clock the same evening. Apparently this is the only reference in literature to Colonel Townshend's case. I have tried in vain to get any other information as to his supposed power of stopping the action of the heart. It is not even mentioned whether he had ever tried it before his final illness in Bath. The necropsy showed a chronic tuberculous disease of the right kidney, a condition often associated with hypertrophy of the heart.

[1] Transactions of the Association of American Physicians, vol. iv.

"AN UNUSUAL CASE OF TUBAL ABORTION."

To the Editors of THE LANCET.

SIRS,—In connexion with this case[1] I have to plead once more that a correct nomenclature is of importance even in gynæcology. The case as narrated is one of tubal pregnancy with recurrent hæmorrhage through the ostium. Tubal abortion it most certainly was not. Had abortion occurred the products and the clot would have been speedily absorbed and no operation would have been necessary. Mr. Sutton's nomenclature is another example of the confusion I predicted when he first introduced the phrase "tubal abortion."

I am, Sirs, yours truly,

Birmingham, Feb. 20th, 1897. LAWSON TAIT.

HOSPITAL FOR INCURABLE FISTULÆ, &c.

To the Editors of THE LANCET.

SIRS,—When the question of distributing the enormous funds which must shortly accrue to the hospitals through the energy of the Prince of Wales, aided by the zeal of the daily papers, duly arises, I trust that the numerous class of most unhappy sufferers for such maladies as the above will not be lost sight of. They are not relieved by any of the existing institutions, which must of necessity refrain from admitting into their wards patients whose lesions emit offensive effluvia and are not quickly remediable by operation. These "pariahs," chiefly female, are usually too poor to pay for the costly personal attention they really need, and hence are a life-long burden to themselves and their friends. A special home for such is a real and urgent want, as I am sure scores of medical practitioners will readily testify. The present year of jubilee would seem to offer an opportunity of remedy.

I am, Sirs, yours faithfully,

Gloucester-place, W., Feb. 13th, 1897. HERBERT SNOW.

"A QUESTION FOR ANÆSTHETISTS."

To the Editors of THE LANCET.

SIRS,—Mr. Lucas's "Question for Anæsthetists" has long been an interesting one to me. For many years past I have always scalded my ether apparatus out after using it. I find two advantages from this: one, the apparatus lasts longer, for nothing in my experience spoils rubber and metal quicker than moist, foul mucus; the other is that I feel that I have not put over my patient's face an apparatus that I would not like to have put over my own. As to the question of causing pneumonia by direct contagion, I think the answer is in the negative, otherwise that disease would be infinitely more common than it is. I believe that the irritation of the ether so injures the mucous membrane of the lungs that a doorway for the bacillus to enter is opened. I suppose, too, that the bacillus pneumoniæ is fairly common in the dust and air, more especially in hospitals where cases of the disease are nearly always present. Of two persons on an athletic sports ground who get chilled or wet, the one who has undergone the fatigues of a race is more likely to get pneumonia than he who is a mere spectator of the race. So here we have a patient depressed by the fear of the operation, by the operation itself, and when we add the intense hyperæmia and even congestion caused by the ether it is no wonder if the bacillus takes up its abode in such a suitable soil as the injured mucous membrane. I am under the impression that so long as we have to deal with a strong irritant like ether we shall have cases of pneumonia following its use, but I do not think they are many in number. Mr. Lucas's "question," however, will do good if its answer is the increasing care by anæsthetists of cleanliness in their work.

I am, Sirs, yours faithfully,

F. WILLIAM COCK, M.D. Durh.

Porchester-houses, W., Feb. 23rd, 1897.

"AN UNUSUAL RESULT OF ABORTION."

To the Editors of THE LANCET.

SIRS,—On Jan. 24th a patient of mine had an abortion starting with sharp labour pains and profuse hæmorrhage. A

[1] THE LANCET, Feb. 13th, 1897, p. 432.

Hosted by Google

fœtus of from fifteen to sixteen weeks was expelled enclosed in an unruptured amniotic sac (with liquor amnii) forming a perfectly transparent envelope without any chorionic or placental tissue. The cord was torn through at the placental insertion and the torn end appeared at the bottom of a depression in the amniotic sac. The placenta was partly adherent to the uterine wall and had to be removed by the finger. During the pregnancy there had been periodic losses of blood. As this was an unusual condition I preserved the specimen with a view to sending it later to a museum. I find now that it agrees with the description in Dr. Purslow's note in THE LANCET of Feb. 13th.

I am, Sirs, yours faithfully,

Appledore, Devon. ALLAN MAHOOD.

"SHOULD EPILEPTICS MARRY?"

To the Editors of THE LANCET.

SIRS,—Dr. Gowers sees no reason to believe that accidental lesions are transmitted and asks me to quote instances. 1. A. B., aged ten years, had one eye destroyed by the lace of a football. His children all had that eye smaller and weaker than the other. 2. C. D. asked me to look at the eyes of his children. He thought they all squinted. The right eye in each case was measurably smaller than the left. C. D., when eight years of age, had his right eye rendered sightless by a needle in a dart thrown by a playfellow. 3 E. F. lost an eye in childhood. His daughter had defective sight; his grandchild is blind. 4. G. H. had his right little finger entangled in a rope when seven years of age and permanently deformed. His children all inherit the deformity.

These cases, amongst others, came under my own observation. I would also refer those who are interested in this subject to an article by Dr. Brown-Séquard,[1] in which he gives many instances as the result of experiment and remarks: "I have never seen epilepsy (in guinea-pigs) except in those having had certain injuries able to produce that nervous complaint, or *in the young born of those injured and therefore epileptic animals.*" As a result of his observation and experiments he concludes: "These facts, added to others mentioned by P. Lucas and Darwin, clearly prove the possibility of hereditary transmission of effects of mere accidental injuries."

The case quoted by Dr. Langworthy[2] is remarkable. He delivered a child whose right eye and right arm were wanting. The father had lost his right eye and had been wounded in the right arm. Dr. Clark[3] attended a child with a stiff knee-joint bent exactly in the same position as the father's, which was also stiff. But it is unnecessary to multiply instances, which abound in the writings of Darwin, the late Professor Rolleston, and others whose observation was keen enough to detect them. If any meaning is to be attached to the term "heredity" it is difficult to exclude the operation of accidental causes or we should be almost driven into the belief that hereditary qualities have always been the "property" of the family in which they occur and have never had an origin. With all due deference, therefore, to Dr. Gowers I consider that a physician is not justified in advising an accidental epileptic to marry or in offering him any prospect of immunity for his possible offspring. I am, Sirs, yours truly,

Feb. 22nd, 1897. WILLIAM G. THISTLE.

THE LATE MR. GEORGE POLLOCK.

To the Editors of THE LANCET.

SIRS,—It may be of interest to record that Mr. George Pollock was in his youth a pupil of the Rev. W. C. Twiss at Wrestlingworth, Beds. The Rev. Mr. Twiss was a man of great originality and humour, and he loved to recount with gusto the escapades of his brilliant pupil. The attachment between the two was very great, and during the last illness of Mr. Twiss, who died in 1888, at the age of ninety years, Mr. Pollock made a special journey down to see him—forty-one miles by rail and seven by road—when himself at the age of seventy-one years. The meeting was not without its pathetic side, and Mr. Pollock afterwards contributed a most touching and affectionate account of the life of his old friend to the *Bedfordshire Press*. I am, Sirs, your truly,

Biggleswade, Feb. 2rd, 1897. J. B. EMMERSON.

[1] THE LANCET, Jan. 2nd, 1875.

THE NEW THEORY OF MALARIA.

To the Editors of THE LANCET.

SIRS,—Dr. Bignami, in his most interesting article summarising the different hypotheses to account for the infection of human beings by the malarial organisms, including the comparatively new theory of inoculation by mosquitos, gives facts which appear to militate against the ground air theory. My object in writing is to ask for a little more light on one of the facts. Great stress is laid upon the experiments showing that it is impossible to pass organisms contained in air through earth, and especially is it difficult to do so when the earth is saturated with water. It seems to me possible to hold that the rainfall increases malaria by raising the subsoil water and so the malarial organisms are forced out of the damp soil where they are produced to the surface in water, and when the water subsides the organisms are retained at the surface. Buchner's theory of the breaking up of the liquid lamellæ scattering the organisms into the ground air would explain, as pointed out by the writer, the passage of the organisms from the surface into the air. Can facts be given disproving the theory of the forcing upwards through the soil of malarial organisms contained in water? I have never heard of earth-worms being considered as vehicles for the passage of malarial organisms to the surface, and yet I see no reason for ignoring them.

Malaria was at one time prevalent in certain parts of England. Were mosquitos to be found in England then? Even now occasional cases of ague are to be found in Kent, Essex, Suffolk, and Lincolnshire. At the great outbreak of malarial disease at Paris, when the Canal St. Martin was excavated, were mosquitos concerned in spreading the malarial organisms?

In 1885 I suggested that the immunity to yellow fever noticed among the negro race and acclimatised Europeans was probably due to a state of the blood the result of malarial poisoning, and in a paper on Immunity which I read to a medical association I suggested that the serum from persons suffering from malaria should be tried in yellow fever. I have since thought that the serum of pigeons affected with the malarial parasites would be more suitable for experimental purposes.—I am, Sirs, yours truly,

HENRY ALSTON,

Feb. 3rd, 1897. Trinidad Medical Service.

THE CONTAGIOUS DISEASES ACTS.

To the Editors of THE LANCET.

SIRS,—In the present state of agitation for the resumption of these Acts in India and the East it may help to strengthen the hands of those interested in this subject if I give, as shortly as possible, the result of my experience of their action during my tenure of office of colonial surgeon and inspector of hospitals in Hong-Kong from 1858 to 1871, during which time they were carried out under my immediate superintendence. The principal medical officers of both navy and army loyally supported me in the matter, and had it been the duty of the health officer of the port to inspect all merchant seamen venereal disease might have been nearly stamped out. No leave was granted to seamen of the Royal Navy without previous medical inspection and detention in hospital if found diseased. The soldiers were carefully watched by their own medical officers, and the whole of the police force underwent a special medical examination once a month. All merchant seamen known to be diseased residing in any boarding-house were obliged under a heavy penalty to be reported to the harbour master and transferred to hospital. All known prostitutes, with the exception of a few Europeans and some half-caste Portuguese who ought not to have been exempted, were examined on an average once a week and if found diseased were detained in hospital; and very few, once I had got the system in proper working order, made any objection, soon being satisfied that it was for their advantage to be so dealt by.

Now what was the sanitary result of all this elaborate machinery? In 1859 both among naval and military invalids the syphilitic amounted to nearly 25 per cent. of the whole,

Hosted by Google

and there was very nearly the same proportion in the Government Civil Hospital. In one crew numbering in all 523 hands, of which 300 had been on the sick list during the last quarter, seventy-seven of these were for venereal diseases, being at the rate of 25·66 per cent. of the total sick, or 14·72 per cent. of the total strength, and that, be it remembered, in a single quarter. In the Government Civil Hospital the proportion of venereal cases was 138 out of 591 admissions, being in the proportion of 23·18 per cent. Exactly ten years later, in 1869, as the result of the working of the Contagious Diseases Acts, that disease had greatly decreased. In the Government Civil Hospital, even in spite of the great number of cases sent in by the harbour master, the percentage of syphilitic cases was reduced to 15·82. In the garrison the percentage of primary disease to the total strength was only 6 83, according to a return furnished me by Dr. Heffernan, Deputy Inspector-General. In the police it was 16·66 against 31·00 per cent. in 1862.

Dr. Maccoun, of the United States ship *Delaware*, on the eve of his departure from the colony, wrote me under date March 12th, 1870, a letter, from which I take the following extracts:—"Since my arrival on this station in the spring of 1868 I have been struck with the benefit derived from the system of registration and inspection of public women so ably carried out in this colony." "During our visits to Hong Kong but few have been infected, and the type of the disease is mild." "Out of a crew of 470 men, only five cases of chancre have been noticed." Dr. W. Home, Principal Medical Officer of the Army, wrote:—"On behalf of the army medical officers stationed here, I have pleasure in expressing to you the great advantage we have received from the excellent sanitary arrangements in force in regard to prostitution." "Venereal disease, from being but a few years ago one of the most common causes of unfitness for duty here has now become of comparatively rare occurrence." Inspector-General Robert Pottinger was still more emphatic and wrote on Dec. 28th, 1870:—"During the years 1849, 1850, and 1851 I was surgeon of the *Reynard* sloop of war on the China station, and though, unfortunately, I am not in possession of my journal for that vessel, I have a vivid remembrance of the sufferings of the crew from syphilitic disease in Hong-Kong. On every occasion when the men had leave ashore, a large proportion of them became affected with the disease, which showed itself in the form both of hard chancre and large, phagadenic sores. Secondary symptoms were also of frequent occurrence, often requiring the patients to be invalided and sent home. The altered state of things at the present time is very striking. During the past nine months that I have had charge of this hospital I have not seen a case of regular Hunterian chancre contracted in Hong Kong, and only a few soft sores which healed readily. Judging from my own experience I should say that syphilis has *all but* disappeared from the colony." Surely the foregoing evidence is sufficient to convince all unprejudiced persons that it is possible to a great extent to reduce, if not to entirely prevent, the spread of this disease by legislative measures. In this short notice I have not entered into any of the questions, moral, sentimental, or otherwise, or the system on which the examinations were based and which met with the unanimous approval of naval medical officers of many different nations; I have limited my remarks to the plain statement of facts, which if required I can greatly extend. I am, Sirs, yours faithfully,

Scarborough, Feb. 22nd, 1897. IVOR MURRAY, M.D. Edin.

HOSPITAL REFORM ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—Now that the subject of Hospital Reform has been fairly placed both before the public and the profession it seems a fitting time to sketch out what our line of action should be in the future. In the first place it is very desirable that the memorial that we have prepared for presentation to the Royal College of Physicians of London should receive the signatures of a large number of practitioners. Sir William Broadbent has stated that a searching and dispassionate inquiry is very desirable, and it would be difficult to find a body better qualified to conduct such an inquiry than the Royal College of Physicians of London. In times gone by many of the most distinguished Fellows of that College took a very warm interest in the question of Hospital Reform; and it is to be sincerely hoped that the same interest will be taken by those Fellows of the College who may be fairly termed leaders of the profession at the present time. The letters of your Special Commissioner have shown that hospital abuse is just as prevalent in some of our large provincial towns as it is in the metropolis, and it will, therefore, be necessary to extend the investigation beyond the limits of London. My association purposes at an early date to organise meetings of the profession in Liverpool, Manchester, Birmingham, Leeds, and Bristol in order that the subject may be thoroughly discussed. May I, in conclusion, make an appeal to the profession to join our ranks? To carry on the work we have undertaken requires both men and money, and although we have no reason for being despondent concerning our future, yet we feel that to ensure success we must have a larger following than we possess at present.

I am, Sirs, faithfully yours,

Cardiff, Feb. 13th, 1897. T. GARRETT HORDER.

HUMANISED MILK.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if any of your readers who have special knowledge on the point could give me an authoritative answer to the following question:—Is the exclusive use of "humanised milk," as supplied by the large dairy companies, liable to produce rickets or scurvy-rickets in infants?—I am, Sirs, yours faithfully,

JOHN MACKERN, M.D. Camb., F.R.C.S. Eng.

Blackheath, Feb. 20th, 1897.

"ELECTIONS OF MEDICAL OFFICERS OF HEALTH: A PROTEST."

To the Editors of THE LANCET.

SIRS,—Of the published appeals for journalistic sympathy which it has been one's lot to read, the ill-conditioned farrago over the patently inappropriate signature "Justitia," in THE LANCET of Feb. 13th at p. 482, appears, on the writer's own statement of the case, to be the most shallow, perverted, and groundless. His grievance is, forsooth, that a young man, holding both a first-rate degree and a first-rate diploma in sanitary science, and possessing the invaluable recommendation of fifteen months' practical work with the health officer of a very large sanitary combination, should be elected to one of its constituent districts which his chief has resigned in preference to your correspondent, although the latter in his letter adduces no evidence of previous practical experience, and has apparently neglected or failed to obtain from his vaunted "courses of instruction in hygiene, bacteriology, and public health chemistry" their ordinary concrete sequel—viz., a D.P.H. He complains that influence was used to secure his well-equipped rival's election, and implies that but for such influence he would himself have been appointed, presumably on what he is pleased to consider his merits. Herein I submit he stultifies himself, for if the appointment were decided solely on the candidates' respective merits, "Justitia," being without previous experience and a D.P.H., would not have had a "look-in," and therefore, in any event, could only have succeeded by that very exercise of influence of which he would now have us believe he is so righteously abhorrent. Further, in admitting that the county medical officer's influence could secure the appointment he confutes his own imputation as to the payment of that official's assistant, for if the medical officer practically *gave up* one of his districts to his assistant (as he has done), is he not to all intents and purposes paying him out of his own pocket? Then, again, his objection that "the assistant will hold it only long enough to get a larger plum," &c., is, as I know from personal experience of a very similar competition with an opposite result, one that may, despite all assertions to the contrary, apply with equal force to "Justitia" himself, and if otherwise, surely his vexation at failing to secure "such a small appointment" is somewhat unaccountable.

The "red-herring" clap-trap about expense to the ratepayers in railway fares and advertising needs no comment, and when your complainant's wrathful disappointment has subsided it is to be hoped he will vindicate his right to his *nom de plume* by recognising the council's wisdom in appointing the candidate to whose superior training and

Hosted by Google

fitness he has involuntarily testified so highly. I may add that my only knowledge of the affair is from your correspondent's letter. I am, Sirs, yours truly,

Feb. 13th, 1897. COUNTY BOROUGH M.O.H.

"MIRROR SPEECH."

To the Editors of THE LANCET.

SIRS,—In connexion with your annotation on mirror speech [1] and Dr. William Elder's paper on Agraphia, read before the Edinburgh Medico-Chirurgical Society,[2] the following suggestions in a letter by M. Gaston Legros [3] may be of interest:—"The right hemisphere contains a centre which presides over the images of letters and words as well as over the movements necessary for their formation, but in right-handed people it remains in a more or less rudimentary condition. In a patient afflicted with right hemiplegia and verbal cecity this rudimentary centre becomes the directing power, and the resulting written speech—which naturally retains the centrifugal direction—is the so-called mirror writing. Let us now consider mirror speech. Here, too, we find evidence of action on the part of the rudimentary right centre. The patient, by reason of the annihilation, or suspension, of his left centres, calls upon those in his right hemisphere; but is it not admissible to infer that the latter in their rudimentary state are not able to act independently of each other? They strive to adjust their individual insufficiency by association. The patient sees his words—having, as it were, written them down in his brain—before articulation, and consequently they are produced orally in centrifugal order. There is here analogy with Charcot's cases of verbal cecity, where the visual memory of a word was supplemented by its graphomotor image and the patients could only read when in the act of writing. The stimulus of the movements required for the formation of the words served to awaken a sense of their signification. A patient with mirror speech can only speak as the result of action in his centres on the healthy side." The foregoing hypothesis is distinctly in favour of the existence of an independent psychic motor which acts through the material brain.

I am, Sirs, yours faithfully,

Jan. 30th, 1897. KITHOGUE.

P.S.—Professor Charles Richet informs a Parisian contemporary that Leonardo da Vinci was in the habit of writing mirror-wise. In his magnificent work on the flight of birds, recently edited in Paris by Th. Sabatchnikoff, the writing is absolutely unintelligible if looked at in the ordinary way, but at once becomes legible when the sheet is reversed and held against the light or before a mirror. Professor Richet believes he has seen it stated that the celebrated painter wrote in this fashion in order to save his discoveries from the pilfering of his rivals, but this hypothesis cannot be founded on fact because it is not likely that pilferers would be deceived by so transparent an artifice. In any case, he adds in conclusion, the fact of the mirror writing is incontestable, and proves that this mode of expressing oneself is not incompatible with genius of the very first order.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The New General Hospital.

THE date of the visit of the Princess Christian to open the new hospital on behalf of Her Majesty has been arranged for the first week in July, the exact day being left to be fixed by Her Royal Highness. Much work still remains to be done in order to render the hospital fit for the reception of patients, but it is expected that sufficient advance will be made during the next few months to justify the opening ceremony being accomplished by that time.

Mason College: Resignation of Professor Wilders.

The following resolution has been passed by the Council of Mason College:—"That Professor Wilders letter be received and entered on the minutes, and that in accepting the resignation by Professor Wilders of the chair of forensic medicine the Council desires to record its regret that on the ground of ill-health Professor Wilders feels himself obliged to sever his connexion with the college and to relinquish a chair which he has honourably and usefully occupied, first at Queen's College and later at Mason College, for a period of thirty years. The council further desires to express its sympathy with Professor Wilders in the cause which has led to his resignation and, as a mark of appreciation of his services in the past and of his position as senior member of the professional body, it requests him to accept the title of 'Emeritus Professor.' The council further desires to have the foregoing resolution suitably engrossed, and, after the signatures of the members of the council and the officers have been appended, to forward it to him." This just and graceful recognition of his services must be very gratifying to the recipient and afford him much satisfaction and pleasurable memories. Already there are five candidates for the vacant post, each with local claims more or less prominent—Mr. Jordan Lloyd, Mr. J. T. J. Morrison, Dr. R. M. Simon, Mr. Wm. Thomas, and Mr. Wright Wilson.

Food Adulteration.

As already mentioned the Health Committee of the City Council have been active in the prosecution of the vendors of adulterated food and drugs. At a recent meeting of the magistrates a local firm was fined £5 for selling sugar which was largely contaminated with foreign matter. The analysis of Dr. Hill, the borough analyst, proved that the samples submitted contained 25 per cent. of carbonate of lime. This is said to be used largely in the bleaching of sugar, but the amount represented appears to be excessive in this instance. The public, we are told, look for a bright and sparkling appearance of the sugar, but they can hardly be credited with the knowledge of how this is obtained or how it can be profitably used in the face of an expert examination. In other cases also the subject of prosecution, two drysalters, were fined £3 and costs for selling glycerine adulterated with 50 per cent. of glucose and labelling the penny bottles "pure glycerine." The defence was a lame one—that others did the same, but it did not exempt them from the infliction of the fine. It is a notorious fact that many persons trading as chemists under the style of drysalters and drug stores are not qualified to dispense drugs, and from them syrup of poppies, paregoric, laudanum, red and white precipitate, and other poisons are obtainable in quantities likely to produce very evil results in their indiscriminate use.

The Treatment of Diphtheria.

An important conference has taken place recently between the health committee and representatives of the board of guardians in order to promote a more general use of the antitoxin treatment of diphtheria. It was stated that in 1896 out of 70 cases of diphtheria which developed in the hospital and were thus treated there was no death. The diagnosis in every case was confirmed by bacteriological examination. It was also pointed out that in 1894 in Birmingham 316 cases of diphtheria were notified in the ordinary way and 50 deaths occurred. In 1895 there were 640 cases and 163 deaths, and in 1896 1100 cases and 246 deaths, giving a percentage of deaths to cases notified for the three years of 21·5 per cent. Some additional information of an interesting kind was also adduced. In relation to this epidemic the following circular has been addressed to the profession in the locality, signed by the Presidents respectively of the Medical Institute, the Midland Medical Society, and the Birmingham Branch of the British Medical Association. "At the request of the health committee of the City Council we have decided to convene a meeting of the members of the medical profession practising in Birmingham, to be held at the library of the Medical Institute on Thursday, Feb. 25th, at 4 P.M., to discuss the best means of dealing with the present epidemic of diphtheria."

Birmingham General Dispensary.

The 103rd Annual Report has just been issued. It states that the income for the year was £7,662 3*s.* 5*d.*, and the expenditure £7,141 6*s.* 7*d.* The total number of patients admitted by tickets has been 35,098, an increase of 2324, and the average cost per patient was 3*s.* 8*d.* There have been 6374 teeth and accident cases admitted without tickets. The amount expended in relief has been over £600, rather more than in previous years.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Female Sanitary Inspectors.

THE sanitary sub-committee of the City Council have recommended, upon the suggestion of the medical officer of health, that two lady sanitary inspectors be appointed. Dr. Hope said the main duties of the female inspectors would be to visit the houses of the lower classes who were habitually dirty, whose dwellings were habitually filthy, and who paid no attention to their own cleanliness or that of their children. The main usefulness of the female inspectors would lie in that direction. Dr. Hope did not anticipate that the female inspectors would meet with opposition in visiting houses, and thought their influence would be similar to that of district nurses—wherever they went cleanliness would follow. Lady inspectors had been a success in Glasgow, and they had been tried in Manchester, but not exactly on the same lines.

The Eye and Ear Infirmary.

The Liverpool Eye and Ear Infirmary appears to be financially in a condition calculated to excite the envy of less fortunate institutions, whose annual reports constantly show an increased debit balance. This happy result has been attained by the receipt of several handsome donations. At the same time the committee wish the charitable public to know that had the funds been in a more prosperous condition at the close of 1895, when there was a debit balance of £355, these donations, amounting to £750, would have been applied to the extinction of the mortgage debt, which still remains at £1000. The hospital possesses no invested funds, and whilst the annual expenses amount to £2200 the reliable sources of income do not exceed £1700. The Hospital Sunday and Saturday contribution amounted to £440. In the out-patient department 6153 new eye cases, and 2204 new ear cases were treated. These cases have been attended to and prescribed for 21,843 and 7538 times respectively. The number of minor operations on out-patients was 1139. The number of important operations in the in-patient department, where 765 patients occupied beds during the year, was 549. The treasurer said this was almost the only instance during his twenty-three years' treasurership when he had been able to show accounts with a credit balance, which now was £55. The term of office of the honorary surgeons to this charity, which is limited to twenty years, differs from that of all the local general hospitals where the sixty years age-limit is the rule. In Mr. Edgar Browne's case this meant retirement at a comparatively early age, when his judgment and operative skill were of especial value to the hospital. While no harm can possibly result from the adoption of the prevalent age-limit, much benefit to the charity would attach to the retention of matured services.

The Lunacy Fee Dispute in the Prescot Union.

The reply of the Commissioners in Lunacy to the communication addressed to them by the clerk of the Prescot Board of Guardians referring to the refusal of Dr. Hall and the other medical men in Prescot to accept a reduced fee of half a guinea for examining and certifying for the removal of pauper lunatics to asylums was in the terms anticipated in my last letter. The Commissioners in Lunacy stated in their reply that they were unable to give authoritative legal opinions on the construction of Acts of Parliament. They also pointed out that a medical man could lawfully refuse to give a certificate for a pauper lunatic unless he was allowed to charge his own fee. If anything serious had happened in the case of Martin Weir from his violence after the medical man had refused to sign the certificate of lunacy, they did not think the latter could have been held responsible. The Commissioners thought that Section 235 of the Lunacy Act, 1890, gave discretion to the justices in regard to fixing a reasonable fee; but if the medical man examined an alleged lunatic before fixing his fee, he could not afterwards demand more than the sum which the justice thought was a reasonable one. The clerk pointed out to the guardians that the Lunacy Act contained a section stating that if the justice would not certify for a guinea fee, the guardians would have to settle the matter with their medical officer.

"The Bacteriology of Fish and the Connexion of Fish with Disease."

This was the subject of a lecture delivered at University College by Professor Boyce. Among the practical points to which he alluded was that of the bacteria which, getting into the alimentary canal of the fish, were not injurious to the fish itself, though the means of communicating typhoid fever and other dangerous diseases to mankind. The precautions to be adopted included frequent and effective cleansing of fish boxes, the gutting and cleansing of the fish at the earliest opportunity, keeping the fish at a low temperature with ice, &c. The lecturer described a disease which sometimes attacked codfish, and which made them as red as salmon; he had some years ago read of a Liverpool costermonger having been brought up on a charge of wilfully dyeing codfish to make them look like salmon. The bacteria which caused this redness of colour had been traced to the salt with which the fish were cured. The preventatives were thorough cleanliness in the fish factories and sterilising the salt of this particular bacterium by subjecting it to artificial heat, not necessarily of a very high degree. A few lantern slides were shown in illustration of the subject, and also of other deleterious changes, such as phosphorescence, which take place in fish.

The Liverpool contributions to the Indian Famine Fund now amount to £21,673 14*s.* 5*d.*

Mr. Heywood Bright has been elected chairman of the General Committee of the Royal Infirmary in the room of Mr. Hamilton B. Gilmour, resigned.

The medical officer of health reports that the death-rate for Liverpool, although still high (25·1 per 1000), is lower than the average for the last ten years.

Feb. 23rd.

WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The University College of South Wales and Monmouthshire.

THE annual meeting of the court of governors of this College was held on Feb. 10th at Cardiff. The President, in reference to the building fund, stated that the Treasury had promised the second £10,000 in three instalments—the first of £5000 and two others of £2500 each. The first £5000 had been paid, and this had been met by a similar sum contributed locally. Last year the Treasury had contributed £10,000 to meet a similar sum contributed in South Wales and Monmouthshire, making a total, with the amount received from their generous friends in the district, of £30,000 towards the building fund. Since then he had been endeavouring to get a sum of £2500 from the subscribers in order to ask the Treasury for another instalment. The chairman reminded the court that the whole £20,000 must be obtained by the end of March. The total amount promised towards the fund was £20,500, and of that sum £16,780 had been paid, and if he could get £750 next week the sum of £2500 could be obtained from the Treasury. The need for new buildings was keenly felt owing to the increase in the number of students. The day students this year had been returned at 418, as against between 370 and 380 last year. Lord Windsor and Dr. W. T. Edwards were elected vice-presidents of the College. Lord Tredegar, Archdeacon Griffiths, Mr. J. Duncan, and Mr. J. A. Jenkins were appointed to represent the College on the Court of the University of Wales for a period of three years.

A Convalescent Home for Bristol.

At a meeting held in Bristol on Feb. 22nd, under the presidency of the Mayor, it was determined that the permanent memorial for the Queen's Diamond Jubilee should take the form of a convalescent home, and that an effort should be made to raise £50,000, one half of this sum being reserved for endowment. A sum of nearly £8500 has been already promised, besides a building which might be converted, at a comparatively small outlay, to the purposes of a home. When the formal appeal for funds is made the residents of Bristol and the neighbourhood will doubtless respond in a generous manner.

The Bristol and Clifton Society for the Prevention of Cruelty to Animals.

The annual report for 1896 shows that during the year 322 cases were brought under the notice of the society's officers; 92 prosecutions were instituted; 91 convictions were obtained; 67 animals were destroyed, either after proceedings and as the alternative to a heavy fine or through the intervention of the

Hosted by Google

society's officers without prosecution; 37 cases were investigated when either the evidence was insufficient or the complaint groundless; and 123 cases were deemed to be sufficiently dealt with by a caution only. The committee of the society regret that but little progress appears to have been made in giving effect to the resolution of the sanitary authority in favour of the establishment of public slaughter-houses, as recommended in the report of the medical officer of health for Bristol (Dr. D. S. Davies).

Cardiff and the Queen's Commemoration.

The Cardiff Chamber of Commerce on Feb. 17th discussed the question of celebrating the Queen's long reign, and a resolution was adopted in favour of erecting a permanent hospital for sailors in lieu of the *Hamadryad* hospital ship. The mayor will shortly call a public meeting in favour of the scheme. The *Hamadryad* has been in use about twenty-five years, and last year 379 in-patients and 11,060 out-patients were treated. The old ship is now getting worn out and will shortly have to be replaced. It is used, not only by seamen, but by townsmen who are injured in the vicinity of the docks. There is every prospect that the project will be carried out.

The Barnstaple Board of Guardians and Vaccination.

Some time ago the magistrates of the county bench at Barnstaple, by the advice of their clerk, held that a vaccination officer must produce written personal authority by resolution of his board for prosecution. The clerk to the guardians did not share this opinion, but believed that these officers were bound by law to prosecute on their own initiative. At the last vaccination prosecution this gentleman informed the magistrates that although he had the authority of the board he did not intend to use that reason, but relied on a recent decision of Mr. Justice Wright and Mr. Justice Bruce. The clerk to the magistrates then adopted this view and the prosecution proceeded without the authority being called for. The clerk to the guardians reported the fact to the meeting held on Feb. 19th, and from the debate which followed it appears that for the future it will be illegal to move that no prosecution shall be taken against vaccination defaulters and the vaccination officers will themselves prosecute whenever necessary without troubling the board. The clerk of the guardians is to be complimented upon his action and it is to be hoped that other boards will follow the example of Barnstaple.

Water-supply of Rhayader.

An inquiry was held on Feb. 10th by one of the inspectors of the Local Government Board in reference to an application made by the Rhayader rural district council to borrow £2120 for works of water-supply for the parish. It is proposed to lay new mains to replace the old ones, which have become corroded, and to supplement the existing supply by means of pumping from the River Wye in dry seasons. The objectors to this scheme opposed the pumping from the river and advocated a gravitation scheme from Nantsarn, which had been commenced but abandoned because an analysis of the water was not satisfactory. A petition in favour of this was presented, which showed that many thousands of sheep were washed in the River Wye and that the sewage from 118 houses entered the river above the intake. The inspector announced that he would have independent analyses of the water made.

Death of the Son of Dr. John Beddoe of Bradford-on-Avon.

Much sympathy is felt with Dr. and Mrs. Beddoe of Bradford-on-Avon, whose son, Mr. C. Beddoe, has met with a fatal accident while with Captain Lugard's exploration party in Central Africa.

Proposed New Hospitals.

Lord Wimborne has offered to make a free gift to Poole of the house and ground known as Poole Mansions to be used as a hospital for Poole and neighbourhood. Lord Wimborne suggests that an endowment fund for the hospital should be the form which the memorial of Her Majesty's Diamond Jubilee should assume, and offers to head the list with a donation of £1000. Lord Wimborne's gift represents about £4000.—At the meeting of the Barry Urban District Council, held on Feb. 5th, the chairman suggested that the Queen's Diamond Jubilee should be celebrated by the erection of a general hospital for the town, and an influential and representative committee of councillors and other gentlemen was appointed to take the question into consideration and to report.

Feb. 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Chair of Medical Jurisprudence and Public Health in Edinburgh.

IT has been intimated here that the profession was interested in the future of this chair, from which Sir Douglas Maclagan has retired; and the profession generally will be pleased that the University Court has declared its approval of the chair being divided. It is understood that this decision has been made practicable by some thousands of pounds left for the purpose by the late Mr. A. L. Bruce and the promise of several thousands towards the same object by an anonymous donor. The new arrangement requires a special ordinance by the Universities' Commission, and that takes several months to obtain. Meanwhile the duties of the combined chair are being performed by Sir Douglas Maclagan's University assistant.

The Edinburgh Medico-Chirurgical Society.

This society held another of its afternoon meetings last week. It, like the former one, was devoted to an exhibition of patients and specimens. As is usual on such occasions, there were a goodly audience and a very interesting exhibition of patients. The cases were mainly surgical, and while in the majority of them nothing but a scar was demonstrable their histories were records of great surgical successes. Necessarily the surgeons have the best of a show of this kind, and after them come the dermatologists. A number of the specimens were related to the cases shown, and thus greater interest attached to them.

Lecture at the Royal College of Surgeons of Edinburgh on "The Parasites in Cancer."

On Friday of last week Mr. Harold J. Stiles delivered one of the newly instituted lectures at the Royal College of Surgeons of Edinburgh. His subject was "The Parasites of Cancer," and the lecture was admirably delivered and illustrated. While it was mainly destructive in its criticism, and not necessarily convincing, it was a contribution of value to the knotty question with which it dealt [1]

Annual Meeting of the Church of Scotland Deaconess Hospital.

The second annual meeting of this hospital was held on Monday. It was stated that a number of deaconesses and missionaries has been trained in the hospital since it was opened two years ago. The average daily number of patients was twenty and the expenditure per bed had only been £36 9s. The hospital is in the happy position of having an income larger than its expenditure.

Royal Hospital for Sick Children, Edinburgh.

The annual meeting of this hospital was held on Monday last. The report showed that 1101 patients were treated during the past year in the wards, while in the out-patient department 7455 medical and 5885 surgical cases were treated. The expenditure for the year exceeded the income by £1043. The number of both the in-patients and the out-patients had considerably increased. The ordinary income had increased, but not in proportion to the increase in the expenditure.

The Indian Famine Fund and Edinburgh Students.

Last week two successful entertainments were given in the Students' Union under the auspices of the Edinburgh Indian Association with the laudable object of raising money for the Indian Famine Fund.

Glasgow Royal Infirmary.

It is understood that a proposal to be endorsed by the Lord Provost and intended as a local memorial of the "Diamond Jubilee" is shortly to be placed before the citizens to the effect that a sum of money be raised for the purpose of effecting considerable alterations in the buildings of the Royal Infirmary. This object is sure to command wide sympathy, and yet it may be fairly questioned whether the proposal is wisely inspired. The Royal Infirmary has now been standing for over a hundred years, and though various alterations have been made at different times the building is for the most part sadly defective in the light of modern hospital requirements. Further, it may be questioned whether any alterations that are within the reach of possibility can ever

[1] A brief abstract of this lecture will be found on page 618.—ED. L.

Hosted by Google

really fit it to meet these requirements. A large sum of money may be spent, and yet in the end, both for treating patients and teaching students, the accommodation and equipment remain most unsatisfactory. The new wine, in short, cannot be contained in the old bottle. But the attention of the directors may be drawn to a more heroic proposal—viz., the re-building of the hospital on a new site. This would secure an entirely new building in harmony with modern demands and also surroundings more suitable to a general hospital than those in the neighbourhood of the present building. Such a site could certainly be found without going too near the limits of the city boundaries, and by a determined effort the money could surely be raised. The infirmary is by far the oldest in Glasgow, it has a long list of distinguished traditions, and its appeal is to the entire community. The occasion which was offered once before has again presented itself. To miss it will almost certainly perpetuate the present unsatisfactory condition for many years, whilst a mere patching up of the old building is not only a much less stimulating proposal, but is a scheme the wisdom of which is fairly open to question.

Medical Appoi ntments.

Mr. George A. Turner, M.D. Glasg., and Mr. J. M. Munro Kerr, M.B. Glasg., have been appointed physicians to the dispensary of the Western Infirmary in the department for Diseases of Women. Mr. W. Burns Macdonald, M.B. Edin., has been elected Medical Officer of Health for the burgh of Dunbar.

Royal Hospital for Sick Children, Aberdeen.

The average length of stay of patients treated in the wards during 1896 was 39⅝ days; annual expenditure per bed occupied, £36 10*s.* 3*d.*; deficit for year (after absorbing legacies), £247 15*s.* 9*d.* The additions now being built will cost £3000, of which £1700 have been already subscribed.

Feb. 23rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

A Case of Leprosy in Dublin.

THE state of the public health of Dublin is still a topic of engrossing interest and of great anxiety to the medical profession as well as to the citizens. The fact that a case of leprosy has been diagnosed by competent authorities in the person of a young man living at the north side of the city is not calculated to allay the feeling. The superintendent officer of public health has been communicated with and arrangements are being made to ensure the deportation of the unfortunate patient.

The Preliminary Examination at the Royal College of Surgeons in Ireland.

It has been stated publicly that the Education Committee of the General Medical Council is now moving for the abolishment of the preliminary literary examinations of the Royal Colleges of Physicians and Surgeons in Ireland. All such examinations have already been given over in England, where certificates of general education must now be produced by aspirants to registration as medical students from competent literary examining bodies. This seems to be a move in the right direction, for it is notorious that many of the examiners in medicine and surgery of the licensing colleges in Ireland have frequently complained of the deficient general education of candidates, and felt themselves obliged to furnish separate reports referring to that deficit as distinguished from want of knowledge of purely medical and surgical subjects.

The Microbe of Bubonic Plague.

The germ associated with the epidemic of bubonic plague in India was exhibited by Professor McWeeney at a meeting of the Scientific and Literary Society of the Catholic University on Monday, Feb. 22nd. It resembles a diplococcus, and is found in large quantities in the blood of infected patients.

The Ulster Hospital for Women and Children.

At the annual meeting held on Feb. 19th it was announced that during the past year there had been 161 children and 80 women admitted into the wards, and 9081 children and 1425 women seen in the out-patient department. The maternity nurse had attended 161 cases. About 4*s.* per head covered all expenses. The establishment of an isolation ward had been of the greatest service, and by its use the medical staff had been able to safeguard the wards from any serious outbreak of infection. Financially there is a sum of £154 to the credit of the institution.

Sir William MacCormac.

A proposal has just been made that the medical profession of Belfast and the vicinity should entertain Sir W. MacCormac, President of the Royal College of Surgeons of England, at a dinner on the occasion of the unveiling of his portrait on March 15th next by the Marquis of Dufferin and Ava at Queen's College, Belfast. Sir W. MacCormac, who is an old student of the College, was, prior to his going to London, surgeon to the Royal Hospital, Belfast.

Belfast Royal Hospital.

At the quarterly meeting of the supporters of this hospital, held on Feb. 22nd, it was reported that during the past quarter 528 intern patients had been treated, while during the same period there had been 5401 new extern cases. The financial condition of the hospital is not satisfactory; the present financial year commenced with a balance against the hospital of £1068 1*s.* 2*d.*, while the expenditure for the five months ending Jan. 31st has been £4340 3*s.* 7*d.*, making a total of £5408 4*s.* 9*d.* The income for the same period has been £3013 1*s.* 5*d.*, leaving a balance against the hospital of £2394 11*s.* 4*d.* The only source of income that has shown any elasticity is that from the working classes, which is £69 7*s.* 2*d.* more than at the same period of last year.

Cork District Lunatic Asylum.

The importance of early treatment in cases of insanity is well shown in one of the statistical tables appended to the report of the medical superintendent of the Cork District Lunatic Asylum for the year 1896. It was found that 40 per cent. recovered among those who had been less than three months ill, but only 13 per cent. were discharged cured of those who had been ill for more than three months before admission, while of those ill twelve months only 8 per cent. recovered. Patients who have once been in an asylum frequently relapse from a slight cause, on the removal of which recovery again takes place; 26 per cent. of those recovered were relapsed cases.

Feb. 23rd.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Private Hospitals.

M. MICHELIN, a deputy, has laid before the Chamber a Bill for the Regulation of Private Hospitals. A scandal has recently electrified Paris, where two months ago two medical men were accused of having procured abortion in a private hospital. They are at present in prison awaiting their trial. The Bill of M. Michelin provides that no private hospital should be allowed to be open without the express sanction of the Prefect of Police, under pain of a fine of from 50 to 500 francs and a term of imprisonment varying from eight days to six months, and that such hospitals, being always under police surveillance, shall be closed upon the first complaint. Every medical man convicted of having performed, or having caused to be performed, a useless operation will be prosecuted as a swindler. The forms of swindling instanced are where the patient's consent is obtained either by an untrue promise of permanent cure or by prognostication of serious complications by which representations an unnecessary operation would be forced upon the patient or money extorted from him. The profession in Paris is naturally irate at these proposals, which lead the public to believe that every private hospital is a dangerous place and that all their surgeons should be under police surveillance. It is quite possible that the medical man accused of having found a fœtus in the patient on whom hysterectomy was performed acted in all good faith. M. Brouardel, Dean of the Faculty of Medicine, drew up a very severe report upon the evidence of the post-mortem and it was mainly this report which led to the arrest and trial. The two medical men who are accused were arrested a long time ago and they are still awaiting trial. The case should have come on at the end of this month but has been adjourned because M. Brouardel has gone to Venice as a delegate to the Sanitary Conference.

France and the Plague.

Excitement about the plague seems to be evaporating. Some articles have recently appeared in the daily press saying that quarantine regulations are illusory because they are not applied universally, and that complete disinfection of the whole of a ship's cargo is impossible. One prominent effect of the regulations is to increase the trade of those ports where they are not in force. Ships which are refused the right of entry to the port of Marseilles discharge their cargo at Genoa, where there are no quarantine regulations, and the merchandise arrives in France by the railway. It has been found that the certificates of certain "ships' doctors" are very often incorrect. These "doctors" are chosen by the shipping companies without any official control and are frequently unqualified men whose only means of livelihood is the holding of a post of this kind. Therefore they often conceal the fact that there are sick on board, the notification of whose illness would delay the unloading of the ship and bring the company into public disfavour. A new law proposes to oblige the companies to carry no one as surgeon who is not properly qualified and has not also passed a special examination in hygiene, epidemiology and bacteriology. The medical men at present holding these appointments have asked leave to continue to hold them without passing this examination which they say is difficult and for which they have no time for study as they are always on the sea. It is true that the greater part of these "doctors," not really belonging to the profession, would starve if they were dismissed without a pension, but on the other hand incomplete or inaccurate certificates are a source of great danger in a time of epidemic.

The Health of the French Navy.

At the Academy of Medicine MM. Vincent and Burot presented some statistics of mortality in the navy. For the five years 1891–95 out of 198,313 men there were 2253 deaths, or 11 per 1000. Tuberculosis was responsible for a quarter of this mortality, and was found to be more frequent in the navy than in the army. Malaria, dysentery, and cholera also showed a heavy death-rate, and so did accidental deaths and drowning. The mortality among the medical officers and dispensers was 19 per 1000.

Regulations for Match Manufactories.

At the same meeting M. Valin read a report which he had prepared to send to the Finance Minister, who had requested the Academy to report upon the question of rendering the manufacture of matches less dangerous to health. The report advised the general adoption of *phosphore blanc*, thorough ventilation of the shops, a careful selection of workers so as to keep out those with any predisposition to bone lesions, and the employment of machinery enclosed in glass cases, so that the worker would be protected from the fumes.

Narrow Escape of a French Alienist.

Whilst engaged seeing fresh patients recently Dr. Charpentier, physician to the Bicêtre Asylum, Paris, had a wonderfully narrow escape from assassination. Soon after he had taken his seat a man, whose appearance afforded no indications of excitement, advanced to the table and said, "Good morning doctor, do you remember me?" "Yes," replied Dr. Charpentier, you are Recq, a former ——." The other, however, did not wait for the conclusion of the sentence. Raising his right hand, which hitherto he had kept concealed in his coat pocket, he aimed a revolver point blank at Dr. Charpentier, so that the muzzle almost touched his breast and fired. Happily the bullet impinged on the victim's sternum, which it failed to penetrate; while with admirable presence of mind M. Siegel, who was standing by, threw himself upon the would-be murderer and prevented him from discharging the other barrels of his weapon. The missile caused a contused wound with slight hæmorrhage, and became flattened against the bone; but Dr. Charpentier was able to continue his service and has not felt any bad effects. It seems that Recq was formerly an inmate at Bicêtre under Dr. Charpentier, and that he has also been confined in other asylums. When he was interrogated as to the motives that induced him to commit such a crime he replied with great coolness that he had been unjustly imprisoned and consequently wished to kill someone in order that attention being thereby drawn to his case he might obtain justice. The certificate, drawn up by Dr. Charpentier, on the strength of which Recq left Bicêtre in 1890, was couched in the following terms:—"A lunatic, persecuted, troublesome, who under the influence of prolonged sequestration has become calm, industrious, submissive; he has abandoned his frenzied ideas and seems to be actuated by good intentions. We are of opinion that he may be set at liberty, but we cannot affirm that he is free from risk of relapse, or that he may not again become dangerous."

Feb. 23rd.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Private Hospitals.

IN large towns like Berlin there are many private hospitals where patients are received for the purpose of having operations performed by surgeons and gynæcologists and other specialists. The necessity for these institutions arises in part from the circumstance that in Germany the opportunities of obtaining appointments in connexion with public hospitals are comparatively few—considerably fewer than in either England or France, and if it were not for the private hospitals many rising young surgeons would have but little scope for the exercise of their talents. Many patients also require special nursing, which they cannot get at home, but for various causes are not eligible as inmates of the public hospitals; they accordingly enter the private hospitals; and it not infrequently happens that surgeons attached to the public hospitals attend such patients and perform operations in the private hospitals. It appears, however, that private hospitals are not looked on with much favour in official circles, and those who are responsible for their management are now placed in a position of some difficulty by the issue of stringent regulations on the subject of their internal arrangements. The requirements of these new regulations are, in fact, so onerous that the entire abolition of the private hospitals seems to be the real object in view. For instance, the windows of patients' wards must not look towards the north, fresh air must be warmed before it is admitted into the rooms, the staircases must have a width of 1·30 metre (4 ft. 4 in.), and the passages a width of 1·80 metre (6 ft.), there must be a sitting-room on each floor, and there must be a garden for the use of the patients. Hardly any of the hospitals and institutions for convalescents at present existing fulfil these requirements, and it would seem that medical men will no longer be able to open establishments of this kind unless they are prepared to have buildings specially erected for the purpose. The new regulations were discussed recently at a meeting of the Public Health Society, and the majority of the speakers were of opinion that such sweeping measures were not in the interest either of the medical profession or the public. If the regulations are enforced the cost of carrying on a private hospital will be greatly increased and the proprietors will naturally protect themselves by raising the fees. Another token of systematic hostility to these hospitals is the fact that they are now officially classified by the Tax Office as industrial establishments, and the proprietors have been requested to pay the so-called industrial tax in like manner with shopkeepers and others engaged in money-making businesses. The medical men connected with the private hospitals naturally consider that they have just grounds of complaint and they have held a meeting in Langenbeck House to protest against the action of the authorities. Professor Bergmann, who was in the chair, pointed out that it is quite unwarrantable to assume, as has been done, that private hospitals are carried on as sources of profit; it is, in fact, sufficiently well known that many medical men not only do not earn anything from their hospitals, but have even to contribute to the expenses. It was also stated that much scientific work is done in the private hospitals, and on various grounds the action of the authorities was strongly condemned. It was eventually decided that the proprietors of private hospitals should form themselves into a union and that they should refuse to pay the industrial tax; arrangements were also made for engaging legal assistance and for bringing the cases before the law courts.

The Antitoxin Treatment of Tetanus.

Dr. Jacob of Petersdorf in Silesia reports in the *Deutsche Medicinische Wochenschrift* a case of tetanus successfully treated by Behring's antitoxin. A boy, aged fourteen years, was shot through the right shoulder on Oct. 13th. Two paper wads, together with stones, pieces of cloth, &c., were

Hosted by Google

removed from the wound, and a week afterwards it was covered by healthy granulations. On Nov. 13th the patient tried to move his arm for the first time, but was unable to do so on account of the rigidity of the muscles. On Nov. 16th Dr. Jacob was sent for in haste and found the patient in a typical state of tetanus. His face was contracted, trismus and opisthotonos had developed, there were tonic convulsions of the muscles of the abdomen, the chest, and the extremities; respiration and deglutition were difficult; there was retention of urine, the bowels were constipated, and violent convulsions occurred when the patient tried to open his mouth. The temperature was 37·6° C. (= 99·6° F.), and the pulse was 160. The urine, which was drawn off with a catheter, was free from albumin and sugar. Morphia and chloral were administered, but without any good result. On the following evening five grammes of Behring's antitoxin dissolved in fifty grammes of water were injected at five places on the right side of the chest and abdomen and one gramme (= 15½ grains) of chloral was given. The patient slept for four hours, but in a day or two the paroxysms were as severe as at first. He could, however, open his mouth better and move his right leg. On the evening an exanthem like scarlet fever appeared on the face, the chest, and the arms. Next day urine and fæces could be passed freely and the right arm and the legs could be moved. On Nov. 20th several convulsions of the extremities were observed, but they were not so strong as before. A second injection of five grammes was given on Nov. 22nd, and since that time the patient's state obviously became better. On Nov. 24th he was able to move his head of his own accord and to open his mouth. On Nov. 25th he could laugh, whistle, and move the vertebral column, in addition to which the convulsions, though still present, were of less duration. By Dec. 11th, when the patient first left his bed, the general attacks had entirely disappeared, but short convulsions of the muscles of the face and the left arm continued till the end of December. Dr. Jacob states that the time of incubation was about twelve days, and that the illness did not begin as usual with trismus, but with a contraction of the muscles near the wound. The beneficial action of the antitoxin was well marked, although it was not possible to give the first injection sooner than the fifth day after the onset of the symptoms, when they had already become severe. The effect of the injection was not immediate, but developed itself slowly, a fact in accordance with the observations of Tizzoni and Cattani.

An Epidemic of Trachoma.

Eastern and Western Prussia, Posen, and Silesia have recently been visited by an epidemic of trachoma, and the cases are very numerous, especially in some districts near the Russian frontier, where the general standard of living is low. The reports of the medical officers of health show that in the district of Johannisburg there are 2343 patients, and in the district of Lyek 3913, of whom 994 are in the town of Lyek, the remainder being in the country. As the town contains only 10,000 inhabitants the number of patients amount to 10 per cent of the total population. In Sensburg there are 913 and in Pillkallen 1322 patients. In the latter district the prevalence among school children is especially remarkable, no fewer than 571 of them having contracted the disease. The Medical Department of the Government organised a conference at Berlin, which was attended by the members of the Department, by delegates from the local authorities concerned, and by the district medical officers of health. It was decided to set apart special wards for trachoma in the ophthalmic hospital of Königsberg University and in the municipal hospitals of Danzig and Königsberg. Lectures on trachoma with practical demonstrations will also be delivered at the above hospitals at the expense of the Government, no fees being charged either to the medical officers of health or to any medical men who may care to attend. Experts are to be appointed by the Government to travel through the infected districts and to attend the poor in conjunction with the local medical men. Trachoma formed the subject of a paper read before the Berlin Medical Society by Dr. Kirchner of Königsberg, one of the medical men who had come to the conference. He said that the above-named eastern districts may easily become the focus of an epidemic owing to the carelessness of the population in hygienic matters. He was of opinion that children should be taught in school the dangers of this disease, and recommended the establishment of public dispensaries in the district towns, together with other measures which may enable poor persons to obtain medical advice and treatment. The district affected by this epidemic is the one where leprosy has recently become prevalent.[1]

The Medical Congresses.

The programmes of this year's medical congresses are now issued. The twenty-sixth Congress of the German Surgical Association will be held at its headquarters, Langenbeck House, in Berlin, from April 21st to 24th, under the presidency of Professor von Bruns of Tübingen. The principal papers to be read are: (1) the Surgical Treatment of Gastric Ulcer, by Professor von Leube of Hamburg and Professor Mikulicz of Breslau; (2) the Value of the x Rays in Surgical Practice, by Dr. Kümmel of Hamburg; and (3) Operations for Prostatic Enlargement, by Professor Helferich of Greifswald. An exhibition of surgical apparatus, dressing materials, &c., will be arranged as usual in connexion with the meeting. The Congress of Internal Medicine will meet this year in Berlin from June 9th to 12th, under the presidency of Professor Leyden. Among the subjects of discussion are: (1) the Treatment of Rheumatic Arthritis, by Professor Baümler of Freiburg and Dr. Ott of Marienbad; (2) Epilepsy, by Dr. Unverrich of Magdeburg; (3) Graves's Disease, by Professor Eulenburg of Berlin; (4) the Aims of Modern Treatment by Means of Drugs, by Professor Liebreich of Berlin; (5) the Prognosis of Spinal Diseases, by Professor Leyden; and (6) the Pathology of Diarrhœa in Children, by Professor Baginsky of Berlin.—The Balneological Association will meet at Berlin from March 11th to 15th.—The German Association of Public Health will meet in Karlsruhe from Sept. 14th to 17th; the subjects to be discussed are: (1) the Disinfection of Dwellings from a Scientific and Practical Point of View; (2) the Diminution of Intemperance; (3) Measures to be taken against Food Adulteration; (4) on School Building; and (5) the Prevention of Epidemics in Health Resorts.

Despatch of a Plague Commission to India.

The German Commission for the study of the plague will leave Germany for India next week. The members are Professor Koch, Professor Pfeiffer of the Institution for Infectious Diseases, Professor Gaffky of Giessen, Dr. Disuderic and Dr. Sticker of the Imperial Health Office. Professor Koch will travel direct to Bombay on the completion of his investigations in South Africa, and till his arrival the leader of the commission will be Professor Gaffky, who was with Professor Koch in British India during the great cholera epidemic of 1884, and assisted him in the researches which finally lead to the discovery of the comma bacillus.

Feb. 22nd.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Italian Army Medical Reports.

FOR the last few years the army medical reports have registered a steady improvement in the health and the general sanitary condition of the Italian troops; but according to the report for 1895, which has just appeared, the results recorded in that year were less favourable than ordinarily. In 1894 the average mortality was 5·2 per 1000, the sickness was 723 per 1000, and the average number of patients in hospital was 30 per 1000; but for 1895 the corresponding numbers were respectively 7·0 per 1000, 743 per 1000, and 33 per 1000, the total on the sick-list being 157,890, of whom 1100 died. The least favourable returns came from the provincial corps and the most favourable from the carabineers. The unhealthiest months of the year, so far as the troops were concerned, were the first four, whereas September, October, and November showed the lightest sick-list. The highest death-rate occurred in the military division of Turin, and the lowest in those of Perugia, Salerno, Naples, Florence, Leghorn, and Rome. Measles and scarlet fever were most prevalent immediately after the arrival of the conscripts in quarters; typhoid fever predominated at the close of summer and the beginning of autumn; and malarial manifestations were most common in July, August, September, and October. The death-rate due to accidents, and also to suicide, reached its maximum in the carabineers, but there was no case under either heading among the bersaglieri, the Alpine regiments,

r the engineers. The mean force of the troops under arms n 1895 was 202,913. The manner in which the report is drawn up is highly creditable to its author, Surgeon-Major Goria; unfortunately it does not give any account of the health of the troops in Africa.

Latest Views on Malaria.

Italy has hitherto maintained a foremost place in the study of malaria, mainly on the etiological or pathogenic side, and a notable contribution to our knowledge of its prophylaxis has just appeared from the pen of the sanitary engineer, Signor Filadelfo Fichera, whose work, "Pel Risanamento delle Campagne Italiane rispetto alla Malaria," has been brought out by the well-known publishers, Hoepli of Milan. It consists of two large volumes, profusely illustrated, in the first of which, after a survey of the latest laboratory research, the author proceeds to discuss the means open to sanitary engineering for combating the fever, first in its diffusion and ultimately in its genesis. An exhaustive bibliography is appended.

Statistics of Sero-therapy in Diphtheria.

The "Società Piemontese d'Igiene," at a recent meeting under the presidency of Professor Bizzozero, discussed the mortality from diphtheria under the new as compared with the old treatment. From statistics carefully compiled by Dr. Abba it appears that 55 per cent. was the proportion of fatal cases up to 1894, whereas in 1895, when sero-therapy was practised for the first time, it fell to 34 per cent. and in 1896 to 31 per cent. Another point made clear by the discussion was the superior safety of rectal injections as contrasted with those practised hypodermically—the former, moreover, being quite as certain as the latter. To save time, always of primary importance, Dr. Abba would apply sero-therapy at once without waiting for bacteriological diagnosis, and longed for the day when families would allow the medical man far greater power of initiative than he now possesses. There was some objection to the postponement of bacteriological examination of pseudo-membrane, as recommended by Dr. Abba; but this was overruled by the President, who threw the weight of his authority on the side of immediate action.

The Health of the Pope.

It is nineteen years almost to a day since Leo XIII. ascended the pontifical throne, and on the 2nd prox. he will have completed his eighty-seventh year. In view of the celebrations prescribed by either anniversary Dr. Lapponi has been peculiarly vigilant in saving His Holiness all needless exertion. The fatiguing functions connected with the coming canonisations, moreover, are another "rock ahead," and Dr. Lapponi seeks to obviate their strain by reducing meanwhile the number of audiences and shortening their duration. His Holiness is at present in very good health; indeed, till the other day Dr. Lapponi's visits had been suspended for weeks at a time. The authors of recent announcements as to "fainting fits" and "intestinal catarrhs" are not well-inspired in the occasions they select for their "industry," as His Holiness invariably stands the winter well, and it is only when the great heat sets in that anything approaching the "deliquii" in question are to be dreaded.

Revision of the "Farmacopea."

The Italian Pharmacopœia is revised every five years, and another revision is imminent. The committee appointed for this work consists of Dr. Emanuele Paternò, Professor of Applied Chemistry in our University (who acts as president); Dr. Luigi Balbiano, lecturer on Pharmaceutical Chemistry and Toxicology in the "Scuola di Farmacia" and Dr. Vincenzo Cervello, Professor of Materia Medica in the University of Palermo. The committee has held its first sitting and important innovations in the text of the Pharmacopœia are expected.

Feb. 23rd.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Scarlet Fever in Budapest.

AN elaborate paper on Scarlet Fever in Budapest since 1882 has just been read before the Budapest Medical Association by Dr. E. Jurkiny. No data of any accuracy were available for the period before 1882 as notification of infectious diseases was not made obligatory until that year. From 1882 to 1896 no fewer than 19,952 persons suffered from scarlet fever in Budapest, the average death-rate being 13·5 per cent. The number of cases was generally lowest in winter and highest in autumn, the latter being the season in which the public schools are re-opened. Dr. Jurkiny found that there was not one single week during the last fifteen years without an occurrence of scarlet fever, and he was in consequence led to the conclusion that the disease must be considered to be endemic in Budapest. At intervals its prevalence assumes the proportion of an epidemic, and there have been three such epidemics since 1882. The first began in May 1886 and lasted eight months; the second began in August, 1890, and lasted till October, 1892, that is to say for a period of twenty-six months; the third lasted from October, 1895, till December of the same year, that is three months. A disinfecting institute opened in September, 1892, succeeded in quickly putting an end to the second prolonged epidemic and was no doubt the means of reducing the third epidemic to a duration of merely three months. Dr. Jurkiny pointed out several causes which combined to neutralise all efforts to stamp out the disease. I will quote only two. First, it happens often enough that poor persons do not call in a medical man, partly because they are unwilling to incur expense, but chiefly because they object to their children being compulsorily removed to a hospital and fear that their furniture will be damaged by disinfection. The present system under which even the poorer classes of the population are made to pay the heavy hospital expenses for their children does not appear to be a good one, especially in view of the fact that the patients are removed to hospital not so much for their own sake as for the benefit of the community at large. Another factor very influential in promoting the disease is the really miserable state of the dwellings of the poor. The town council may spend large sums in providing a better water-supply and better drainage, and in carrying out other sanitary reforms, but it will not put an end to the endemic of scarlet fever until it radically improves the housing of the poorer classes.

Intubation preceding Tracheotomy.

Professor J. Bókay recommends intubation as a preparatory operation in difficult cases of tracheotomy, having very often found that tracheotomy was exempt from accidents of any sort when free respiration was provided for by means of intubation. His first operation of this kind was performed quite independently of others as early as the year 1891, and he has since then repeated it some sixty times.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

Corporal Punishment.

RESORT to the rod, if one might believe some sensational writers, is as common in Russia as imprisonment in other countries. That it was so at one time—or rather, that resort to the rod used to be more frequent in Russia than elsewhere—may possibly be true. With the unlimited power formerly possessed by the landowner over the serf, it is not very surprising that this was so. But since the great Act of Emancipation in 1861 not only has corporal punishment come to be much more rarely inflicted than in the old days, but public opinion, or, more exactly, the opinion of the *intelligentzia* or educated classes, has undergone a considerable change in the way it regards this question. There has been a growing feeling that the use of the rod has a degrading and demoralising effect on the individual submitted to it, apart from the serious and unjustifiable physical injuries it sometimes produces. The power of inflicting corporal punishment is now no longer in the hands of the serf-owner, but in those of the *zemstvos*, and several *zemstvos* have in recent years decided to abolish entirely this mode of punishing crime in their district and have even approached the Government urging its universal abolition throughout the country. At the last conference of Russian practitioners in memory of Pirogof the question was the subject of brief discussion, though no formal conclusion was arrived at. It was, however, decided to form a committee to collect information bearing on the subject, and this committee has now

Hosted by Google

addressed a circular to the profession asking for information on the following points:—1. What facts are there indicating that corporal punishment may lead to severe psychical, nervous, or other "somatic" derangements of the health of those submitted to it? 2. Are there instances of persons already in ill health—e.g., with phthisis, heart disease, &c.—having been subjected to corporal punishment? 3. Points bearing on the medico-legal aspect of the question. 4. The literature of the subject. It was requested that all information on these points should be sent to Dr. Jbanof, Smolensk, or to Dr. Yakovenko in the Government of Moscow.

The Jubilee of Anæsthesia.

The first operation under ether in St. Petersburg was performed just fifty years ago by the great surgeon Pirogof. It was a removal of the breast in a woman and the whole procedure was done most successfully and rapidly in no more than a minute and a half. The patient was quite unconscious and felt no pain. On the same day—Feb. 14th (26th), 1847—and in the same hospital—the large military hospital on the quays of the Neva—Pirogof operated with equal success on another patient, and two days later he performed two more operations under the newly-introduced anæsthetic in the Obukhovski Hospital. It is stated that a week before Pirogof's first operation ether had been employed in a similar case in one of the Moscow hospitals, but the patient is said to have felt pain, although she had inbaled ether for twenty minutes. On Feb. 23rd (March 7th) a woman underwent amputation of the thigh without feeling any pain whatever, but the administration of ether had lasted as long as forty-five minutes in her case. It seems probable that imperfections both in the purity of the ether and in the form of the inhaler contributed to the delay in producing complete anæsthesia.

Lectures on Plague.

In view of the outbreak of plague in India the Imperial Army Medical Academy in St. Petersburg has arranged for two extra courses of lectures—one on the History of Plague, by Dr. Skoritchenko, Professor of the History and Encyclopædia of Medicine; and a second on the Clinical Aspect and Bacteriology of the disease, by Dr. S. Botkin, Professor of Infectious Diseases and Bacteriology.

Anti-diphtheritic Serum as a Prophylactic.

A certain educational institution recently requested an opinion from the Academy on the desirability or otherwise of inoculating every pupil in the institution with anti-diphtheritic serum as a prophylactic measure, diphtheria having already made its appearance among the pupils. The matter was submitted to the *Conferentzia* of the Academy (or committee of professors), and their reply was recently published. It is to the effect that such prophylactic injections would, in their opinion, be useless. This *ex cathedrâ* statement seems worthy of record.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

The Syrian Protestant College.

THIS college was opened in 1866 at Beirut in Syria, and during the last quarter of a century the medical department has sent out many graduates who are employed in civil and military careers in Egypt. The college is under trustees in New York, and depends locally upon a committee of twenty-four American and British residents in Syria and Egypt, nearly all of whom are reverend missionaries. English is now the language of all three departments of the college, preparatory, collegiate, and medical, but all Arabic-speaking students are given, besides, a thorough course of instruction in their own language. Chemical, zoological, and bacteriological laboratories are now provided for the students, besides an astronomical observatory, museums of all sorts, and a library containing 8000 volumes, mostly English. The medical faculty consists of seven professors, who divide the professional subjects between them. Medical students are not admitted till the age of seventeen, and are then put through a course of four years. The following text-books among others are used:—Attfield's Chemistry, Gray's Anatomy, Bruce's Materia Medica, Parkes's Hygiene, Kirkes's Physiology, Roberts's Medicine, Druitt's Surgery, and Hart and Barbour's Gynæcology. The average number of medical students is between fifty and sixty, and there are in addition fifteen pharmaceutical students. When successful in their final examinations at the college they have to go to Constantinople to be examined for their degrees before the Imperial Medical School. Ward work is provided in the Johanniter Hospital near the college, where there are sixty-three beds and an out-patient department of 14,000 cases in the year.

Quarantine Board at Alexandria.

The presidency of this most important department has just become vacant owing to the ill-health of Mr. Miéville, who has held the post since 1884. Dr. Armand Ruffer, who had hardly settled into the chair of pathology at the Medical School in Cairo, has now been selected to preside over the international members of the Quarantine Board. This is a loss to the Medical School, but a great gain to Egypt. It is believed that the new president will be able to make authoritative statements about disease which it will be difficult for the most anti-English member to gainsay. Dr. Mackie, who has been for many years the English member of the board, is also obliged to resign by reason of ill-health and his place at Alexandria will be filled by Dr. D. H. Attfield, at present quarantine officer at Suez and director of the pilgrims' camps during the Haj.

Venice Congress.

The Government officials selected to represent Egypt at the Plague Congress at Venice are Muhammad Pasha Cherif, Under Secretary of Foreign Affairs, and Mr. Milton, Director of Kasr-el-Aini Hospital.

Cairo, Feb. 10th.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations, and having conformed to the by-laws and regulations, have been admitted Members of the College, and are now entitled to practise medicine, surgery, and midwifery:—

Allen, Charles Percival, L.R.C.P. Lond., Middlesex Hospital.
Allen, James Lynn, L.R.C.P. Lond., Cambridge University and St. George's Hospital.
Ambrose, George Patrick, L.R.C.P. Lond., Westminster Hospital.
Arthur, Joseph Hugh, L.R.C.P. Lond., London Hospital.
Ashford, William, L.R.C.P. Lond., St. Thomas's Hospital.
Baird, Roy Fearon, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
Barton, Charles Nathaniel, L.R.C.P. Lond., St. George's Hospital.
Beards, Ernest Jonathan, L.R.C.P. Lond., Mason College, Queen's, and General Hospitals, Birmingham.
Bebb, Richard, L.R.C.P. Lond., London Hospital.
Bennetts, Archibald James, L.R.C.P. Lond., St. Mary's Hospital.
Bernhardt, Dudley Richard, L.R.C.P. Lond., St. Mary's Hospital.
Berry, Herbert George, L.R.C.P. Lond., St. Bartholomew's Hospital.
Berry, Sidney Herbert, L.R.C.P. Lond., Charing-cross Hospital.
Binckes, Frederick William, L.R.C.P. Lond., St. Thomas's Hospital.
Blackwood, John, L.R.C.P. Lond., University College Hospital.
Bletchly, George Payne, L.R.C.P. Lond., Middlesex Hospital.
Booker, Charles William, L.R.C.P. Lond., Guy's Hospital.
Bottomley, Francis Carr, L.R.C.P. Lond., Cambridge University and St. George's Hospital.
Bremridge, Richard Harding, L.R.C.P. Lond., Oxford University and St. Bartholomew's Hospital.
Buendia, Nicolas, L.R.C.P. Lond., University of Columbia, Botago, and St. Bartholomew's Hospital.
Burney Charles Dudley Francis, L.R.C.P. Lond., Charing-cross Hospital.
Burt, Albert Hamilton, L.R.C.P. Lond., King's College Hospital.
Caley, Thomas Aloysius, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds, and Royal Infirmary, Edinburgh.
Carnes, William, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Chevallier, Claude Lionel, L.R.C.P. Lond., St. Thomas's Hospital.
Clarkson, Colin Campbell, L.R.C.P. Lond., University College Hospital.
Clough, William Henry, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Cobbledick, Arthur Stanbury, L.R.C.P. Lond., University College and Royal Infirmary, Bristol.
Coutts, John Morton Sim, L.R.C.P. Lond., University College Hospital.
Dakin, Thomas Burns, L.R.C.P. Lond., London Hospital.
D'Amico, Carmelo De Piro, L.R.C.P. Lond., University of Malta.
Densham, Walter Arnold, L.R.C.P. Lond., Charing-cross Hospital.
Dobie, Robert Douglas, L.S.A. Lond., King's College Hospital.
Dodson, George Everard, L.R.C.P. Lond., St. Bartholomew's Hospital.
Dykes, Charles Reginald, L.R.C.P. Lond., University College and Royal Infirmary, Bristol.
Eardley, William, L.R.C.P. Lond., Cambridge University and London Hospital.
Eddy, James, L.R.C.P. Lond., Middlesex Hospital.

Hosted by Google

Edleston, Richard Shafta Chambers, L.R.C.P. Lond., St. Bartholomew's Hospital.
England, Humphrey, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital and Hants Royal County Hospital.
Evans, Wilfred Felix, L.R.C.P. Lond., St. Bartholomew's Hospital.
Farr, Arthur, L.R.C.P. Lond., Charing-cross Hospital.
Finch, William Stanley, L.R.C.P. Lond., University College, Liverpool, and University College, London.
Fogarty, Daniel, L.R.C.P. Lond., Ledwich School, Dublin, and St. Mary's Hospital.
Fordham, John William, L.R.C.P. Lond., London Hospital.
Fox, Edward Joseph, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
Fulton, Henry, L.R.C.P. Lond., Guy's Hospital.
Gilbert, Leonard, L.R.C.P. Lond., St. Thomas's Hospital.
Godson, Francis Arthur, L.R.C.P. Lond., Cambridge University and Guy's Hospital.
Goffe, Ernest George Leopold, L.R.C.P. Lond., University College Hospital.
Goldie-Scott, Thomas, L.R.C.P. Lond., Edinburgh University.
Good, Hardman Allgood, L.R.C.P. Lond., King's College Hospital.
Grant, Alfred James, L.R.C.P. Lond., St. Thomas's Hospital.
Greenwood, Arthur Rowland, L.R.C.P. Lond., Middlesex Hospital.
Greenwood, Henry Harold, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Grummett, Charles Christopher, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
Harding, William Joshua, L.R.C.P. Lond., St. Bartholomew's Hospital.
Harris, Noel Hugh, L.R.C.P. Lond., St. Bartholomew's Hospital.
Hartley, James Victor, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Hasslacher, Francis Joseph Maria, L.R.C.P. Lond., King's College Hospital.
Haynes, George Secretan, L.R.C.P. Lond., St. Bartholomew's Hospital.
Herrington, Edmund William, L.R.C.P. Lond., St. Mary's Hospital.
Howlett, George Dalziel, L.R.C.P. Lond., St. Mary's Hospital.
Hudson, Corrie, L.R.C.P. Lond., University College and Royal Infirmary, Bristol, and Charing-cross Hospital.
Hughes, John Brierley, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
Hunt, Edward Lewis, L.R.C.P. Lond., St. George's Hospital.
Jennings, Richard Edward William, L.R.C.P. Lond., University College and Royal Infirmary, Bristol, and St. Bartholomew's Hospital.
Joynson, Alfred William, L.R.C.P. Lond., Royal College of Surgeons and Adelaide Hospital, Dublin, and Charing-cross Hospital.
Langdon, Henry Charles Theodore, L.R.C.P. Lond., Cambridge University and St. Bartholomew's Hospital.
Langworthy, Edward Southwood, L.R.C.P. Lond., St. George's Hospital.
Lewis, Cecil Ernest Millington, L.R.C.P. Lond., Cambridge University and Middlesex Hospital.
Liversidge, William, L.R.C.P. Lond., University College Hospital.
Lynch, Stephen Frederick, L.R.C.P. Lond., King's College Hospital.
Marriage, Herbert James, L.R.C.P. Lond., St. Thomas's Hospital.
Marsh, Henry Rupert, L.R.C.P. Lond., Guy's Hospital.
Mayston, Robert William, L.R.C.P. Lond., Guy's Hospital.
Michôd, Frederick Archibald Hope, L.R.C.P. Lond., St. Mary's Hospital.
Millichamp, George Ernest, L.R.C.P. Lond., Toronto General Hospital and Toronto University, and London Hospital.
Moore, Julius, L.R.C.P. Lond., Guy's Hospital.
Mudd, Frank Burnand, L.R.C.P. Lond., Middlesex Hospital.
Neild, Newman, L.R.C.P. Lond., Owens College and General Infirmary, Manchester.
Norrington, Lawrence Weekes, L.R.C.P. Lond., University College and General Infirmary, Bristol.
Oxley, Alexander Wemyss, L.R.C.P. Lond., University College Hospital.
Oxley, William Henry Francis, L.R.C.P. Lond., Firth College, Sheffield, and St. Bartholomew's Hospital.
Parker, Lionel Edmund Longworth, L.R.C.P. Lond., St. George's Hospital.
Parsons, Harold Campbell, L.R.C.P. Lond., Toronto General Hospital and Toronto University.
Parsons, Henry Francis, L.R.C.P. Lond., University College and Royal Infirmary, Bristol.
Priestley, Thomas, L.R.C.P. Lond., Firth College, Sheffield, and University College Hospital.
Reynolds, Leonard Grugeon, L.R.C.P. Lond., Guy's Hospital.
Richards, William Jones, L.R.C.P. Lond., St. Bartholomew's Hospital.
Roach, Sidney, L.R.C.P. Lond., St. Bartholomew's Hospital.
Robinson, John Charles Reynolds, L.R.C.P. Lond., St. Thomas's Hospital.
Ross, Murdoch William, L.R.C.P. Lond., Otago University, New Zealand.
Scanlon, Leonard Edmund, L.R.C.P. Lond., Owen's College and Royal Infirmary, Manchester.
Scowby, Edward Thomas, L.R.C.P. Lond., Guy's Hospital.
Sessions, Frederick Leonard, L.R.C.P. Lond., Owen's College and Royal Infirmary, Manchester.
Somers, Charles Dudley, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
Stansfeld, John Stedwell, L.R.C.P. Lond., Oxford University, Royal Infirmary, Glasgow, and Charing Cross Hospital.
Stevens, Herbert John, L.R.C P. Lond., Charing Cross Hospital.
Sutcliffe, William, L.R C.P. Lond., Mason's College, Queen's and General Hospitals, Birmingham.
Sworn, Arthur Benjamin Richman, L.R.C.P. Lond., University College Hospital.
Tarbet, William Edward, L.R.C.P. Lond., University College, Liverpool, and University College Hospital.
Taylor, Frank Edward, L.R.C.P. Lond., Yorkshire College and General Infirmary, Leeds.
Temple, Percy George, L.R.C.P. Lond., Guy's Hospital.
Thomas, Ellis Rae, L.R.C.P. Lond., Guy's Hospital
Thomas, Herbert John, L.S.A. Lond., University College and Royal Infirmary, Bristol, and Guy's Hospital.
Thomas, Robert Russell, L.R.C.P. Lond., St. Bartholomew's Hospital.
Torrance, James, L.R.C.P. Lond., Otago University, New Zealand, and St. Bartholomew's Hospital.
Townsend, Henry William Worth, L.R.C.P. Lond., Cambridge University and St. Thomas's Hospital.
Tulk-Hart, Thomas John Augustus, L.R.C.P. Lond., Guy's Hospital.
Turnbull, Hugh Prideaux, L.R.C.P. Lond., St. Georges's Hospital.
Vulliamy, Justin Theodore, L.R.C.P. Lond., St. Thomas's Hospital.
Walker, William Percival, L.R.C.P. Lond., Owens College and Royal Infirmary, Manchester.
Wall, James Bligh, L.R.C.P. Lond., St. Mary's Hospital.
Wallis, William, L.R.C.P. Lond., Anderson's College, Glasgow, Firth College, Sheffield, and Charing-cross Hospital.
Ward, Ellacott Leamon, L.R.C.P. Lond., Middlesex Hospital.
Waters, John Frank William, L.R.C.P. Lond., Middlesex Hospital.
Waters, William Arthur Pernow, L.R.C.P. Lond., Oxford University and Middlesex Hospital.
Watkins, John Prestwood, L.R.C.P. Lond., Guy's Hospital.
Watson, George Trustram, L.R.C.P. Lond., Cambridge University and St. George's Hospital.
Whicher, Stanley, L.R.C.P. Lond., Guy's Hospital.
White, Malcolm, L.R.C.P. Lond., St. Thomas's Hospital.
Wiggins, William Denison, L.R.C.P. Lond., St. Mary's Hospital.
Willis, Harry Alexander Legge, L.R.C.P. Lond., St. Mary's Hospital.
Wills, Bertram Shera, L.R.C.P. Lond., St. Thomas's Hospital.
Wood, John Hutchinson, L.R.C.P. Lond., Durham University and St. Bartholomew's Hospital.

CONJOINT BOARD OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations have been admitted Diplomates in Public Health—viz.:

Boulton, Arthur, M.R.C.S. Eng., L.R.C.P. Lond., Cambridge University and Charing-cross Hospital.
Erskine, Alexander McConnell, M.B., B.Ch., B.A.O. R.U.I., Queen's College, Belfast, and Royal University of Ireland, Dublin.
Evans, John Morton, L.R.C.P. Lond., M.R.C.S. Eng., Glasgow and London Hospital.
Gardiner, Peter, M.B., C.M. Glasg., Glasgow University, Edinburgh and St. Mary's Hospital.
Howse, Percy William McDowall, F.R.C.S. Eng., L.R.C.P. Lond., L.S.A., London Hospital.
Jones, William Black, M.D. Lond., L.R.C.P. Lond., M.R.C.S. Eng., St. Bartholomew's Hospital.
Mapleton, Henry Banbury, M.B., C.M. Edin., Edinburgh University and University College Hospital.
Maynard, Edwin, M.R.C.S. Eng., L.R.C.P. Lond., London Hospital.
Parker, Henry Thomas, M.D. Lond., M.R.C.S. Eng., L.R.C.P. Lond., St. Bartholomew's Hospital.
Richards, Joseph Stewart, M.D. Lond., L.R.C.P. Lond., M.R.C.S. Eng., St. Bartholomew's, University College, and Guy's Hospitals.
Roberts, George Augustus Edward, M.R.C.S. Eng., L.S.A., Middlesex Hospital.
Russell, Charles Henry, L.R.C.P. Lond., M.R.C.S. Eng., Charing-cross Hospital.
Smith, Sydney Calvin, L.R.C.P. Lond., M.R.C.S. Eng., Middlesex Hospital.
Steegman, Edward John, M.B., B.S. Durh., M.R.C.S. Eng., L.R.C.P. Lond., Durham University, St. Mary's and University College Hospitals.

Nine gentlemen were referred for six months.

UNIVERSITY OF LONDON.—At the Intermediate Examination in Medicine in January the following candidates were successful in the subjects indicated:—

ENTIRE EXAMINATION.

First Division.—Frederick Charles Borrow, St. Bartholomew's Hospital; and Percy Cooper Colls, King's College.
Second Division.—John White Alared, Owens College; Cornelia Bonté Sheldon Amos, London School of Medicine for Women; Hanway Richard Beale, St. Thomas's Hospital; Harold Selwyn Capper, University College; Clement Woodthorpe Chaplin, London Hospital; David Davies, University College; Henry George Drake-Brockman, St. George's Hospital: Annie Chapman Gowdey, London School of Medicine for Women; John Lupton Holt, Yorkshire College; William Sam Inman, Sheffield Medical School and Firth College; Kenneth Fraser Lund, University of Cambridge and University College, Liverpool; Louisa Martindale, London School of Medicine for Women; George Norman Meachen, Guy's Hospital; Bernard Elwell Potter, Charing-cross Hospital; Herbert Midgley Reeve, Guy's Hospital; William Hartley Tattersall, Owens College; Ethel Miller Vernon, London School of Medicine for Women; and William Bertram Watson, St. Mary's Hospital.

EXCLUDING PHYSIOLOGY.

First Division.—Frederick Fenn Elwes, Middlesex Hospital; and Erle Evans, London School of Medicine and Birkbeck Institute.
Second Division.—Ernest Clarkson Bourdas, St. Thomas's Hospital; Charles Richard Brown, Harold Burrows, William Henry Cazaly, B.A., and John Moore Collyns, St. Bartholomew's Hospital; Wilfrid Henry Coltart, Birmingham Medical School; Walter Seymour Danks, St. Bartholomew's Hospital; John Bernard Davey, Middlesex Hospital; Edward Percy Hughes Dudley, St. Bartholomew's Hospital; Susan Jane H. Eastwick-Field, London School of Medicine for Women and Royal Free Hospital; Alexander Fraser, Guy's Hospital; Cecil Scarlett Frost, Thomas Hall Gandy, and John Stansfield Gayner, St. Bartholomew's Hospital; Ernest Cutcliffe Hadley, Mason College; William Walter Harrison, Guy's Hospital; Philip Maynard Heath,

Hosted by Google

University College; James Gerald Fayrer Hosken, and Seymour Alfred Millen, St. Bartholomew's Hospital; Arthur Moon, Guy's Hospital; James Robert Morton, London Hospital; Bertram Wilmore Moss, Guy's Hospital; David Thomas Price, Bristol Medical School; Charles Gabriel Seligmann, St. Thomas's Hospital; Walter Grahame Stewart, Guy's Hospital; Philip Graham Stock, University College, Bristol; Margaret Helen Style, London School of Medicine for Women; Alfred Bertram Vine, Middlesex Hospital; John Frederick Walker, London Hospital; Charlotte Louise Weetman, London School of Medicine for Women; Albert John Walton Wells, St. Bartholomew's Hospital; and Robert Bardley Byam Wilmot, St. Mary's Hospital.

PHYSIOLOGY ONLY.

First Division.—Thomas Aubrey, University College, Bristol; George Valentine Miller, University College; Walter Bernard Secretan, Guy's Hospital; and John Godfrey Cresswell Taunton, Mason College.

Second Division.—Frank Butterfield, Owens College and Manchester Royal Infirmary; Arthur Hunton Carter, Guy's Hospital; Charles Edwin Durrant, St Thomas's Hospital; Herbert Devas Everington, St. Bartholomew's Hospital; Herewald Evelyn Croker Fox, Guy's Hospital; Edward Alfred Gates and Francis Ley Augustus Greaves, St. Thomas's Hospital; Helen Beatrice Hanson, London School of Medicine for Women; Henry William Harding, St. Thomas's Hospital; Ronald Hatfield, St. Bartholomew's Hospital; Edgar Leach, Owens College; Theodore Marles Thomas, University College; Joseph Arthur Mawson, Yorkshire College; John Austin O'Dowd, Mason College; George Chetwode Owsley, Guy's Hospital; Arthur Ricketts, University College; Harold Alfred Schölberg and Sydney Richard Scott, St. Bartholomew's Hospital; Jeremiah Thornton, London Hospital; and Lewis Augustus Walker, St. Bartholomew's Hospital.

ROYAL COLLEGE OF SURGEONS IN IRELAND: Fellowship Examination.—Mr. Ernest George Fenton, L.R.C.S. Irel., &c., having passed the necessary examination, has been admitted a Fellow of the College.

The following gentlemen have passed the primary part of the Fellowship examination:—

F. Warren, J. M. M. Crawford, S. R. Godkin, and H. Pringle.

FOREIGN UNIVERSITY INTELLIGENCE.—*Tomsk:* Dr. Th. T. Romanoff has been appointed Extraordinary Professor of Pathological Anatomy.—*Breslau:* Dr. Heinrich Sachs has qualified as *privat-docent* of Internal Medicine.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The death of the following eminent foreign medical man is announced:—Dr. Max von Schleiss Löwenfeld, formerly Body Surgeon to King Maximilian II. of Bavaria, at the age of eighty-seven years. He published works on many subjects, especially dealing with language from a psychological point of view. His latest work was "Theses cosmologicæ septuaginta," which appeared in 1882. His father was an authority on medical jurisprudence and a great champion of vaccination in Bavaria.

SOUTHPORT CONVALESCENT HOSPITAL.—The annual meeting of the Southport Convalescent Hospital was held on Feb. 11th. Alderman J. Unwin presided, and remarked that the hope he expressed last year that the number of patients would exceed 5000 had been fulfilled, for there had been 5058. The governors of the Cotton Districts Convalescent Fund had sent 1767, as against 1636 in 1895. The committee had decided to make a grant of £500 from year to year to the governors of the Cotton Districts Convalescent Fund to assist them in an extension of the hospital, which would provide about fifty additional bedrooms and would increase the day-room accommodation.

THE SOCIETY OF MEDICAL OFFICERS OF HEALTH AND THE VACCINATION COMMISSION.—A meeting of the Society of Medical Officers of Health was held at the offices of the Board of Works for the St. Giles's District on Friday last, Dr. T. P. Bate, the president, being in the chair. Dr. R. Dudfield presented a draft report from the council upon a paper on the "Report of the Royal Commission on Vaccination," communicated by Dr. Bond. In the report the council endorsed all that the Commissioners said in favour of general re-vaccination and expressed regret that no suggestions had been made by which such general re-vaccination might be secured. They held that the State should not waive its right of compulsion in relation to vaccination by introducing a "conscience clause" in any future legislation, and recommended the society to oppose such alteration of the law, as being a dangerous innovation, both on social and hygienic grounds, as they considered the danger of vaccination to have been greatly exaggerated. The report concluded with a long list of recommendations of changes in the mode of enforcing vaccination in the event of a Bill being introduced to give effect to any, or all, of the recommendations of the Royal Commission.

DR. LAWRIE of Weymouth has promised a donation of £100 towards establishing a Children's Convalescent Hospital in the town in commemoration of the Queen's reign.

DR. FERRIER has been elected a member of the Athenæum Club under the complimentary provisions of Rule II., which empowers the annual election by the committee of nine persons of distinguished eminence in science, literature, the arts, or for public services.

UNIVERSITY OF CAMBRIDGE.—Dr. Donald MacAlister has been appointed an Elector to the Professorship of Pathology; Professor Clifford Allbutt an Elector to the Professorship of Surgery; Dr. S. Ringer an Elector to the Downing Professorship of Medicine; and Sir W. H. Flower an Elector to the Professorship of Anatomy.

A DEPUTATION from the Bradford and District Medico-Ethical Society has interviewed Mr. Wanklyn, Member of Parliament for the Central Division of Bradford, and explained to him the strong objections to the Midwives Registration Bill. Mr. Wanklyn promised to oppose the Bill. The society obtained a promise to the same effect from Captain Greville, the Member for the Eastern Division of Bradford, at the time of his election last year.

ON the 20th inst, at a meeting of the Crickhowell branch of the St. John Ambulance Association, Lady Bailey, the wife of the Lord Lieutenant of Brecknockshire, presented those members who had recently qualified in "first aid" with their certificates. Subsequently her ladyship, on behalf of the class, presented to the lecturer, Mr. P. E. Hill, M.R.C.S. Eng., a handsome silver-mounted malacca walking-stick, bearing a suitable inscription.

AT a recent meeting of the subscribers to the Sir Augustus Harris Memorial Fund it was decided that the memorial should take the form of a drinking-fountain, to be erected by the western wall of the Covent-garden Opera House and the provision of a bed at the Charing-cross Hospital, to be known as the Sir Augustus Harris Memorial Bed. An executive committee was appointed to carry out these objects, and it is understood that £2000 have been subscribed.

LIVERPOOL CANCER HOSPITAL.—The annual meeting of the Liverpool Cancer Hospital was held on Feb. 19th at the town hall, Alderman Radcliffe presiding. The report for 1896 showed that there were 232 in-patients during the year, being an increase of 52 over the number for 1895. The average daily number in the hospital was 25 and the whole of the beds were frequently in use at the same time. The attendances of out-patients were 30,561, or an average of over 100 per day, and it was now absolutely necessary to enlarge the out-patients' department. The accounts showed a considerable excess of expenditure over income.

MANCHESTER ROYAL LUNATIC HOSPITAL.—The report of the committee of the Manchester Royal Lunatic Hospital, better known perhaps as the Cheadle Asylum, states that during the whole of last year the accommodation for patients, both in the main building as well as in the neighbouring houses, has been taxed to the uttermost. Mr. Mould, the medical superintendent, in his report, says that the recoveries for the year were more than 50 per cent. on the total number of admissions. The deaths were somewhat in excess of the usual average, the greater number from general paralysis and hopelessly incurable brain diseases. The great age attained by many of the patients was remarkable, and the average age at death was sixty-five years.

PROPOSED INFECTIOUS DISEASES HOSPITAL IN CHESTER.—The Chester town council have applied for a loan of £20,000 for the erection of an infectious diseases hospital, the proposed site for which is part of an estate at Sealand belonging to the corporation. At an inquiry held at the Chester town hall by the inspectors of the Local Government Board the town clerk explained that the present arrangements for the treatment and isolation of fever cases were inadequate, and the infirmary board did not see their way to continue them. The hospital would provide accommodation for forty-six beds. The inspectors after examining the plans proceeded to visit the locality, and will report to the Local Government Board on the subject.

UNIVERSITY OF BRUSSELS.—At the February examination for the M.D. degree Mr. J. R. Gaudoin, L.S.A., passed with honours. Mr. John O. Moore, L.R.C.P., F.R.C.S. Irel., and Mr. Charles Butler, L.R.C.P. Lond., M.R.C.S. Eng., also received the degree.

MEDICAL MAGISTRATE.—Mr. William Kickham Heffernan, medical officer of the Killenaule Dispensary, has been appointed to the commission of the peace by the Lord Chancellor on the recommendation of the Earl de Montalt, Lord-Lieutenant of the County Tipperary.

LEEDS GENERAL INFIRMARY.—Two new operating theatres, divided from one another by the instrument room, have just been provided at the Leeds General Infirmary. They have skylights in the roof and windows at the sides and are also lighted by electricity. A plot of land in Sunnybank-terrace, immediately behind the Infirmary, has been recently bought, and will be used as a site for a supplementary Home for the nurses.

MONKWEARMOUTH AND SOUTHWICK HOSPITAL.—The extension of the Monkwearmouth and Southwick Hospital was formally opened on Feb. 16th by Lady Williamson, who unlocked the Williamson ward with a golden key presented to her on behalf of the executive committee. Sir Hedworth Williamson, the president of the hospital, made a speech congratulating the managers on the successful completion of the work. On the afternoon of the following day the general public were freely admitted to inspect the new wards.

FINSBURY DISPENSARY.—At the annual court of governors of the Finsbury Dispensary, Brewer-street, E.C., held on Feb. 18th, the committee announced that Mr. R. D. Dalál, M.R.C.S. Eng., L.R.C.P. Lond., had been appointed resident medical officer in succession to Mr. Alfred Philipps, M.R.C.S. Eng., L.S.A., who had resigned after twenty-six years' tenure of office, and had been made an honorary life governor. Mr. Dalál is a Parsee and a native of Bombay; he studied medicine at St. Bartholomew's Hospital and is supposed by some to be the first of the Queen's Indian subjects to receive a public medical appointment in England. At the same meeting Sir Dinshaw Petit, Bart., of Bombay, was elected a vice-president of the institution.

NOTTINGHAM HOSPITAL FOR WOMEN. — The annual meeting of the Castlegate Hospital for Women, Nottingham, was held on Feb. 17th at the Exchange, Mr. E. Bond presiding. The report of the medical staff stated that the work of the hospital during the past year had been highly successful. There had been 145 in-patients, on whom 111 operations had been performed, and there had been 7 deaths, including 2 cases which were admitted in a semi-moribund condition. In the out-patient department 843 new cases had presented themselves for treatment. Anæsthetics had been administered 111 times with no casualty and no case of septic disease had arisen in the hospital. The statement of accounts showed that the whole of the debt on the building fund had been paid off and that the balance due to the bank had been reduced to £608.

ABERDEEN ROYAL INFIRMARY.—The 157th annual report shows that 2124 cases were treated in the infirmary during 1896 at a total cost of £7903 14*s.* 10*d.*, or £49 17*s.* 4*d.* per bed. The ordinary income (£6769) was £1134 short of the ordinary expenditure, and £1458 was applied out of the extraordinary income (£3818) to meet the deficit. Lady students are now admitted to attend hospital practice. It is hoped the new medical block—the last part of the re-construction scheme—will be fit for occupation before Midsummer. The Hospital Saturday movement brought £550 to the infirmary and £50 to the convalescent hospital; 175 patients were admitted to the latter institution. Satisfactory progress is being made with the construction of the new convalescent hospital at Hillhead of Pitfodels. Of the 2124 infirmary patients, 776 were medical and 1348 were surgical cases. Deducting patients who died within forty-eight hours of admission the death ratio in medical cases was about 1 in 8·7 and in surgical cases 1 in about 29. Besides the above, there were 3249 out-patients—viz., 224 medical, 692 surgical, 1437 casualty, and 896 eye cases. The average number in hospital was 158·5 and the average number of days in hospital, 29·5.

CAMBRIDGE AND DISTRICT MEDICO-ETHICAL SOCIETY.—The following officers have been appointed:—President: Dr. Carver. Vice-President: Professor Allbutt. Treasurer: Mr. Deighton. Secretary: Mr. Penberthy. Committee: Professor Bradbury, Mr. Edwards, Mr. Cox, Mr. Fordyce, Mr. Hyde Hills, Dr. Roper, Dr. Ingle, and Mr. Syme.

GUY'S HOSPITAL INSTITUTION FOR TRAINED NURSES.—The twelfth annual report of the Guy's Hospital Institution for Trained Nurses shows that the work of the institution has been carried on during the past year with increasing activity and success. Applications for nurses have reached 1191, as compared with 1150 in the preceding year, and the applications have exceeded by 240 the actual number of cases for which nurses were supplied. The number of cases actually nursed was 951 and the fees received by nurses amounted to £6798. The nurses vary in number from 85 to 90. The institution is managed by a board consisting of four *ex-officio* members—the President, the treasurer, the superintendent, and the matron of the hospital, together with three representatives of the governors and two representatives of the medical and surgical staff elected annually.

HUNTERIAN SOCIETY.—The annual meeting was held at the London Institution on Wednesday, Feb. 10th, 1897, at 8 P.M., the President, Dr. G. E. Herman, in the chair. The following is a list of the officers who were elected for 1897-98:—President: Dr. G. E Herman. Vice-Presidents: T. H. Openshaw, M.S., Hingston Fox, M.D., S. H. Appleford, M.D., and F. J. Smith, M.D. Treasurer: F. Charlewood Turner, M.D. Trustees: H. I. Fotherby, M.D., and F. M. Corner, M.R.C.S. Librarian: T. H. Arnold Chaplin, M.D. Orator: Peter Horrocks, M.D. Secretaries: A. H. Tubby, M.S., and Arthur T. Davies, M.D. Council: Sir Hugh Beevor, M.D., J. S. E. Cotman, M.R.C.P. Edin., L. A. Dunn, M.S., Fortescue Fox, M.D., Hope Grant, F.R.C.S. Edin., J. W. Oliver, M.D., W. Rawes, M.D., H. J. Sequeira, M.R.C.S., St. Clair B. Shadwell, M.D., L. E. Shaw, M.D., G. J. B. Stevens, M.R.C.S., and J. F. Woods, M.D. After the annual meeting the society adjourned to the Theatre of the London Institution to hear the Hunterian Oration by Dr. Hingston Fox on the "Life and Times of Dr. William Hunter," an abstract of which was published in our columns last week.

DIPHTHERIA IN LONDON.—There was noticeable diminution in the amount of diphtheria in London during the first four registration weeks of the current year, as compared with the preceding like periods. In the last five weeks of 1896, which year had fifty-three weeks for registration purposes, there were no less than 1442 notified cases of diphtheria in the county, and these yielded a weekly average of 288, four districts of the metropolis having as many as 432 cases notified in them in the period and all the sanitary areas suffering invasion. In the succeeding four weeks ended with Jan. 30th there were only 915 notified cases, and one district recorded no notification of the disease, the weekly average for the county being 229, and only three districts having upwards of 50 notified cases, with 246 in the aggregate. Other three districts had only 4 notifications between them. Thus, in so far as amount of disease is concerned, the period was of a distinctly more hopeful character than many of its predecessors. In the last period of 1896 the deaths registered yielded a weekly average of 51, and presented a per case mortality of 17 8 per cent. of the notifications. In the four weeks of the present year the registered deaths were 239 in number, and the per case mortality as high as 26·1 per cent. Of course we have here to contend with deaths in many instances resulting from cases notified in the preceding period, but even so the mortality rate is very high. Coming to the three completed weeks of February we find that matters so far as fatal diphtheria is concerned are still favourable. Thus in the week ended Feb. 6th the deaths, which in the three preceding weeks had numbered 52, 63, and 53 respectively, fell to 46, although still 5 in excess of the corrected decennial average for the fifth week of the period 1887-96. Camberwell was credited with 7 deaths and Hackney with 5 deaths. The whole of the 46 deaths were of young persons aged under twenty years, and 883 patients suffering from the disease were left in hospital at the close of the week. There were as many as 14 deaths registered from diphtheria in the week in the outer ring, of which 8 occurred

Hosted by Google

in persons residing in the West Ham district. In the week ending Feb. 13th there was a further satisfactory fall in the number of registered deaths to 37—a number actually 2 below the corrected decennial average for the particular week. Only one of these was in the person of an adult over twenty years of age. Mile-end Old Town and Camberwell had each four deaths credited to them, and the hospitals at the close of the week contained 877 diphtheria patients, the admissions in the week having been 104, as compared with 93, 116, and 95 in the three preceding weeks. In the outer ring there were 11 deaths registered, 3 being in West Ham district. In other words, there were 25 deaths in the suburbs of London in the fortnight, as compared with 49 in the thirty-two great towns of the Registrar-General outside London in the same period. Last week the deaths registered from diphtheria in London numbered 40—a number 5 in excess of the corrected decennial average for the seventh week. Camberwell area had 6 deaths credited to it, Lambeth and Greenwich each 4, and Wandsworth 3 deaths. Only one of the 40 deaths was of a person aged over twenty years, and 5 were of infants under one year of age. The admissions to hospital in the week were 104 in number and the cases remaining in hospital on Saturday last 853, against 881 at the same period of January. The deaths registered from diphtheria in the outer ring last week fell to 8, half of which were in the West Ham registration district.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Petroleum Lamp Accidents.

THE House of Commons has re-appointed the Select Committee on the keeping, selling, using and conveying of petroleum and other inflammable liquids, and the precautions to be adopted for the prevention of accidents with petroleum lamps. The committee consists of Sir Thomas Carmichael, Mr. Jesse Collings, Mr. Alexander Cross, Mr. Fortescue Flannery, Sir Edward Hill, Mr. Wootton Isaacson, Mr. Lyon, Mr. McKillop, Mr. Mundella, Mr. Pollock, Mr. Harold Reckitt, Mr. Compton Rickett, Sir Benjamin Stone, Mr. Tully, and Mr. Ure. The Committee will meet at once, and it is hoped will very shortly complete its inquiry, which has already extended over two sessions.

Medical Officers to Volunteer Corps.

During the debate in Committee of Supply on the vote for the Volunteers Colonel Sir H. Howard Vincent called attention to the work of medical officers in volunteer corps, and represented to the War Office that these officers should receive the equipment allowance of £20 recently given to combatant officers in the same service.—Mr. Brodrick, Under-Secretary of State for War, undertook to consider the matter.

Introduction of Lord Lister.

Lord Lister took his seat in the House of Lords for the first time on Tuesday, Feb. 23rd. His lordship was introduced by Lord Watson and Lord Playfair.

HOUSE OF COMMONS.

THURSDAY, FEB. 18TH.

Pauper Children in London.

Mr. Hazell asked the President of the Local Government Board whether the remanded children, who were one of the classes for whom it was proposed to establish the new Metropolitan Children's Asylums' Board, under the Local Government Board, were already under the Home Office and the London School Board; and whether, seeing that it was through the action of the School Board that many of them were first apprehended, and that they were subsequently placed under the Home Office, he would consider the advisability of leaving the temporary provision for them in the hands of one or other of the authorities which already had to deal with them.—Mr. Chaplin replied that under the existing law the guardians, and the guardians alone, were responsible for the care and maintenance of children who, prior to the question of an order being made for removal to an industrial school being determined, were remanded to the workhouse. In many workhouses there was no suitable accommodation for these children, or only accommodation which did not properly provide for their being kept separate from other inmates. The provision of such accommodation for children of either sex in each of the thirty unions in the metropolis, with the necessary staff for supervision, would entail a very considerable expenditure—an expenditure greatly in excess of what would be entailed by separate provision for children of the class referred to. The total number of such children for which provision would be required would probably be not more than 100 or 120.

Disease in the Army in India.

Lord George Hamilton, replying to a question on this subject, informed the House that the Departmental Committee consists of Lord Onslow, President, Sir James Peile, member of the Council of India, Surgeon-Major-General W. Taylor, Army Medical Department, and Surgeon-Colonel J. Richardson, Indian Medical Service (retired).

FRIDAY, FEB. 19TH.

The Payment of Medical Officers.

Sir Walter Foster asked the President of the Local Government Board whether his attention had been called to the action of the West Bromwich Guardians in appointing a district medical officer at a fixed salary, which was to include payment for all those cases which the Consolidated Order of July 24th, 1847, expressly provided should be paid for as extras, and whether Articles 177 to 183 of this Order had been suspended as regards the West Bromwich Union; if so, whether he would inquire if the reasons which justified the suspension still held good, seeing that the Local Government Board last year called special attention to the articles of the order which required that district medical officers should have extra remuneration for operations and certain other cases.—Mr. T. W. Russell, on behalf of Mr. Chaplin, replied: The operation of the articles in the regulations relating to the payment of extra fees to medical officers in the West Bromwich Union was suspended in 1862 on the application of the guardians. The guardians stated that they proposed this arrangement in consequence of continual disputes in connexion with claims by the medical officers to fees. All the medical officers of the Union who have been appointed since that time have been appointed at salaries inclusive of the extra fees. The Local Government Board have not received any suggestions from the guardians or the officers that the arrangement is not working satisfactorily.

Death-bed Evidence.

Sir Matthew White Ridley, replying to a question put to him by Mr. Pickersgill, said he had seen the newspaper reports of the trial of the case Regina *v.* Greatorex Smith, an indictment for performing an illegal operation. It appeared from those that the learned judge decided that, under the circumstances, the statement made by a young woman when in a dying condition was inadmissible in evidence. That being so, it became, of course, a matter of regret that she should have been troubled upon her death-bed. He was satisfied, after careful inquiry, that the police inspector in reading over to the prisoner on his arrest a portion of the statement which the young woman had made, and, secondly, in taking the prisoner to the bedside of the dying woman and putting questions to her in his presence, did no more, under painful and difficult circumstances, than his duty in endeavouring to obtain the evidence of the young woman—the sole witness—by the only means in his power. He could not admit that his conduct deserved censure. If he thought that it was a growing practice on the part of detective officers of the Metropolitan Police to attempt to get in as evidence statements which would otherwise be inadmissible by arranging that they should be made in the prisoner's presence or read over to him, he would certainly take action in the matter.

MONDAY, FEB. 22ND.

Vaccination in the Post Office Service.

Mr. Channing asked the secretary to the treasury, as representing the Postmaster-General, whether the attention of the Post Office authorities had been called to the case of Miss Annie Jane Maxted, appointed six months ago as an assistant or clerk to the department, then pronounced healthy and strong, compelled as a condition to appointment to be re-vaccinated, suffered in consequence it is stated for six months, terminating in death on the 2nd instant; whether there was any authority by statute to enforce the above condition; whether it was ordered by the department assuming the power; and whether, while the recommendations of the Royal Commission were unconsidered by Parliament, the order would be continued.—Mr. Hanbury: The attention of the Postmaster-General has been called to the case of Miss Maxted, but the facts are not as represented to the hon. Member. Miss Maxted was not pronounced healthy and strong six months ago; on the contrary, the medical officer who examined her reported that she was not strong and was suffering from an enlargement of the superficial cervical glands of the neck. The cause of her death is certified to have been lymphadenoma (Hodgkin's disease), and as a secondary cause dermato-melasma suprarenale (Addison's disease), and neither of these resulted from the re-vaccination. Re-vaccination as a condition of appointment in the Post Office is enforced, not by Statute, but by Post Office regulations. The regulation has been in force since 1863, and in view of the remarkable immunity from small-pox enjoyed by Post Office servants under this regulation it is not proposed to alter it.

Metropolitan Pauper Children.

Mr. Chaplin, replying to a question put by Dr. Farquharson, said he was informed by the managers of the Metropolitan Asylum District that during the year 1896 275 children suffering from scarlet fever and 15 from diphtheria were removed from Poor-law schools in the metropolis (including two certified schools) to asylums of the managers. There were no cases of small-pox. The schools from which children were removed were the separate schools of Islington, Hackney, Strand, Holborn, Shoreditch, Bethnal Green, St. George-in-the-East, Lambeth, and Westminster, and the schools of the Kensington and Chelsea, Central London, Forest Gate, and North Surrey school districts. Children were also removed from the *Exmouth* training ship and from the North Hyde and St. Agnes Orphanage certified schools. The managers further informed him that it was not possible to state with precision what had been the cost of each patient per week, but that the average cost might be put at about 21*s.* per week per patient, this sum including maintenance and common charges.

TUESDAY, FEB. 23RD.

Mortality in India.

Lord George Hamilton said, in reply to a question, that he had received the following information regarding mortality in the Central Provinces. The total number of deaths for the year 1895 was 349,137 and for 1896 it was 468,469. The latter year was exceptionally unhealthy, and it appeared that cholera deaths were 37,479 in excess of those in 1895; fever, 69,342; diarrhœa and dysentery, 9566; small-pox, 1103; other causes, 11,842. This mortality gave for the whole year a death-rate of 36·03 per 1000 in 1895 and of 49·03 per 1000 in 1896 on the present population.

Hosted by Google

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BELL, F. O., M.B., C.M. Edin., has been appointed Medical Officer for the Workhouse and the Second Sanitary Wareham District of the Wareham and Purbeck Union.

COPEMAN, A. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the South Welvey Sanitary District of the Downham Union.

COWIE, GEO., M.B., C.M. Aberd., has been appointed an Assistant Medical Officer of the Infirmary, City of London Union.

DYSON, WILLIAM, M.B., Ch.B. Vict., has been appointed a House Surgeon to the Manchester Royal Infirmary.

FAGGE, *d.* W., M.R.C.S., has been appointed a House Surgeon to the Leicester Infirmary.

FLETCHER, D., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for Applecross, Ross.

FOULERTON, A. G. R., F.R.C.S., has been appointed Pathologist to the Chelsea Hospital for Women, Fulham-road.

FOX, E. J., M.B, C.M. Edin., has been appointed a House Surgeon to the Manchester Royal Infirmary.

FOX, G. M., L.R.C.P. Lold., M.R.C.S., has been appointed Medical Officer for the Walsall Workhouse, vice J. Wood, retired.

HAMPER, C. N., M.B., C.M. Edin., has been appointed *pro tem.* Medical Officer to the Chislehurst, Sidcup, and Cray Cottage Hospital.

HARDING, ANNIE, L.S.A. Lond., has been appointed on the Medical Staff of St. Stephen's Hospital, Delhi, in connexion with the Cambridge Mission.

HAWLEY, ARTHUR, L.R.C.P. Lond., M.R.C.S., has been appointed an Honorary Medical Officer to the Coventry and Warwickshire Hospital.

HERBERT, W., M.R.C.S., L.R.C.P., has been appointed Assistant House Surgeon to the Royal Hants County Hospital, Winchester.

HIGGINSON, C. G., L.R.C.P. Lond., M.R.C.S., has been appointed a House Physician to the Manchester Royal Infirmary.

HOWLETT, EDMUND H., F.R.C.S., has been appointed Surgeon to the Hull Royal Infirmary, vice J. Sherburne, resigned.

MCARTHUR, D. C., L.R.C.P. Lond., M.R.C.S., has been appointed *pro tem.* Medical Officer for the Fifth Sanitary District of the Hertford Union.

MONTGOMERY, R. J., M.A., M.B. T.C.D., F.R.C.S. Irel., has been appointed Assistant Surgeon to the St. Mark's Ophthalmic Hospital, Dublin.

PARK, J. W., M.D., C.M. Edin., L.D.S. Eng., has been appointed Dental Surgeon to the North-Eastern Hospital for Sick Children, Hackney-road, Shoreditch.

PAYNE, G. S., M.R.C.S., has been re-appointed Medical Officer of Health by the Thorney Rural District Council.

POMFRET, H. W., M.D. Vict., Ch.B., L.R.C.P. Lond., F.R.C.S., has been re-appointed Surgical Registrar to the Manchester Royal Infirmary.

RODGER, JAS., M.D., C.M. Aberd., has been appointed a Consulting Physician to the Aberdeen Royal Infirmary Incorporation.

ROXBURGH, WM., M.B., C.M. Glasg., has been appointed a Certifying Factory Surgeon for the district of Troon, Ayrshire.

STORRS, C. S., M.B., B.C. Camb., has been appointed Clinical Assistant to Out-patients at the Chelsea Hospital for Women, Fulham-road.

WALKER, F. J., M.D. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse of the Spilsby Union.

WHITWELL, JAMES R., M.B, C.M. Edin., has been appointed Medical Superintendent to the Suffolk County Asylum, Melton.

WILKINSON, A. T., M.D., M.R.C.P. Lond., M.R.C.S., has been appointed Medical Registrar to the Manchester Royal Infirmary.

YARROW, G. E., M.D. Heidelb., L.R.C.P. Lond., M.R.C.S., D.P.H., has been re-appointed a Medical Officer for the City of London Lying-in Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ANCOATS HOSPITAL, Manchester.—Resident Junior House Surgeon. Salary £50, with board and washing.

BELGRAVE HOSPITAL FOR CHILDREN, 77 and 79, Gloucester-street, S.W.—Resident House Surgeon, for six months. Board, lodging, and washing provided.

BRENTFORD UNION.—Medical Officer and Public Vaccinator for the parish of Chiswick. Salary as Medical Officer £150 per annum, with certain stipulations as to medicines, midwifery, and vaccination fees. Applications to the Clerk, Union Offices, Isleworth.

BRISTOL GENERAL HOSPITAL.—Physician-Accoucheur and an Assistant Physician-Accoucheur.

CANCER HOSPITAL (FREE), Fulham-road, S.W.—House Surgeon for six months. Salary at the rate of £50 per annum, with board and residence.

CHELSEA, BROMPTON, AND BELGRAVE DISPENSARY, 41, Sloane-square, S.W.—House Surgeon and Secretary. Salary £95 per annum, with furnished rooms in the Dispensary House, an allowance of £20 for coals and candles, and a further allowance for a housekeeper.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant for three months.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician, for six months. Salary at the rate of £30 per annum, and board and residence provided.

EAST LONDON HOSPITAL FOR CHILDREN, Glamis-road, Shadwell, E.—House Surgeon. Board, lodging, &c., provided. No salary.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark-bridge-road, S.E.—Junior Resident Medical Officer. Salary £50.

GENERAL INFIRMARY, Northampton.—Assistant House Surgeon, unmarried. Salary £100 per annum, with furnished apartments, board, attendance, and washing.

HULL ROYAL INFIRMARY.—Honorary Assistant Surgeon for the out-patient department, for five years.

LIVERPOOL ROYAL INFIRMARY.—Honorary Physician.

LONDON HOSPITAL MEDICAL COLLEGE, Mile-end, E.—Demonstrator of Physiology. Salary £100 a year. Also Assistant Demonstrator of Anatomy. Salary £90 a year.

PARISH OF WESTRAY, Orkney.—Medical Officer and Public Vaccinator. Salary as Medical Officer £90 sterling per annum. Applications to Mr. Jas. Sinclair, Clerk, Parish Council, Westray.

ROYAL SURREY COUNTY HOSPITAL, Guildford. — Resident House Surgeon. Salary £80, with board, lodging, and laundry.

SHEFFIELD PUBLIC HOSPITAL FOR DISEASES OF THE EAR, THROAT, AND SKIN.—Honorary Physician for the out-patients. Also Honorary Physician for the out-patient department for Diseases of the Throat.

STAMFORD HILL AND STOKE NEWINGTON DISPENSARY, 189, High-street, Stoke Newington, N.—Junior Resident Medical Officer. Salary for the first three months at the rate of £50 per annum, and afterwards at the rate of £75 per annum, with board and residence in each case.

ST. LUKE'S HOSPITAL, LONDON, S.E.—Clinical Assistant for six months. Board and residence provided.

ST. THOMAS'S HOSPITAL, Westminster-bridge. — Resident Assistant Physician.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—Professor of Anatomy. Applications to the Secretary and Registrar, University College, Cardiff.

WARWICK COUNTY LUNATIC ASYLUM, Hatton.—Second Assistant Medical Officer. Salary £130, rising to £150, with full board.

WEST LONDON HOSPITAL, Hammersmith-road, W.—House Physician and House Surgeon, for six months. Board and lodging provided.

WHITECHAPEL UNION INFIRMARY, Vallance-road, E.—Resident Assistant Medical Officer. Salary £120 per annum, in addition to rations, furnished apartments, coal, gas, and washing. Applications to the Clerk to the Guardians, Union Offices, Vallance-road, Whitechapel, E.

WOLVERHAMPTON EYE INFIRMARY.—House Surgeon, for twelve months. Salary £60 per annum, with rooms, board, and washing.

Births, Marriages, and Deaths.

BIRTHS.

ALEXANDER.—On Feb. 17th, at Mayhurst, Paignton, the wife of James Alexander, M.D., of a son.

MORRIS.—On Feb. 16th, at *Gordon Lodge*, Charlton-road, Blackheath, the wife of Clarke K. Morris, M.R.C.S.E., of a daughter.

SHERRINGTON.—On Feb. 21st, at Grove-park, Liverpool, the wife of C. S. Sherrington, M.D., F.R.S., of a son.

SOULBY.—At Grimsby, on Feb. 17th, 1897, the wife of C. Ernest Soulby, M.D. Brux., M.R.C.S. Eng., of a daughter.

TRACEY.—On Feb. 19th, at The Gables, Willand, Cullompton, Devon, the wife of H. Eugene Tracey, M.B., of a son.

WARDE.—On Feb. 18th, at Knowsley, Prescot, the wife of Wilfrid B. Warde, M.B., of a daughter.

MARRIAGES.

BOTT—RICHARDSON.—On Feb. 23rd, at the Chapel Royal, Savoy, by the Rev. Paul Wyatt, M.A., Chaplain, Dr. William Gibson Bott, of Newington, to Janet Campbell Richardson, of Glenholm, Whitehaven, second daughter of the late Robert Richardson, Esq.

FRY—PRINCE.—On Feb. 24th, at Marylebone Parish Church, Walter Ernest Fry, M.R.C.S., L.R.C.P. Lond., of Wateringbury, to Frances Mary (Cissie), eldest daughter of Julius Charles Prince, Esq., of Wimpole-street W.

HENSLEY—LOW.—On Feb. 24th, at the Priory Church, St. Bartholomew the Great, Philip John Hensley, M.D., F.R.C.P., of Henrietta-street, Cavendish-square, to Marie, eldest daughter of Maximilian Low, Esq., late of Park-road, Haverstock-hill.

JOSCELYNE—BEASLEY.—On Feb. 18th, at St. Augustine's, Penarth, Glamorganshire, Edward Walter Joscelyne, M.B., of Southwick, Sussex, to Constance Emily Warren, daughter of Ammon Beasley, of Northcliff, Penarth.

TIDCOMBE—BULL.—On Feb. 23rd, at St. Peter's, Hammersmith, Francis Sitwell Tidcombe, M.R.C.S. Eng., L.R.C.P. Lond., L.S.A., of Bognor, Sussex, to Alice Jane Frances, second daughter of the late Henry Bull, solicitor.

DEATHS.

CRAIGIE.—On or about Feb. 3rd, at Pietermaritzburg, Natal, John Craigie, M.D., aged 54 years.

CRAWFORD.—On Feb. 14th, suddenly, William Smyth Crawford, B.A., F.R.C.S. Edin., of Mount Pleasant, Liverpool, in his 38th year.

GOSSE.—On Dec. 29th, at Wallaroo, South Australia, John Gosse, M.R.C.S. Eng., in his 51st year.

HUTCHINGS.—On Feb. 12th, at Young, New South Wales, Arthur Carey Hutchings, M.D., in his 46th year.

MOORE.—On Feb. 15th, at Chardwar, Bourton-on-the-Water, John Moore, M.R.C.S., aged 76 years.

POWER.—On Feb. 17th, at Hoe-park-terrace, Plymouth, Surgeon-Major Edward Richard Power, late Army Medical Staff, aged 42 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (1st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M., Ophthalmic 1.15 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), Westminster (2 P.M.).

TUESDAY (2nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (2 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY (3rd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.).

THURSDAY (4th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.)

FRIDAY (5th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.).

SATURDAY (6th).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (1st).—MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. F. de Havilland Hall: Diseases of the Nose and Throat in Relation to General Medicine. (Lettsomian Lecture.)

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-square, W.C.).—8 P.M. Paper:—Mr. J. H. Badcock: Copper Amalgam, its Merits and Demerits; and also an affiliated paper on the same subject by Mr. A. Goadby.

TUESDAY (2nd).—PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Papers: Mr. J. Hutchinson, jun., and Mr. E. Frazer: (1) Series of Specimens of Epithelioma of the Penis; Specimens illustrating the Changes in the Submaxillary Gland secondary to Cancer of the Mouth.—Dr. F. J. Smith: Aneurysm of the Aorta in a Boy.—Dr. C. Ogle: Dermoid Growth involving the Lung.

THURSDAY (4th).—NEUROLOGICAL SOCIETY OF LONDON.—8.30 P.M. Communications on Muscle Spindles by Dr. F. E. Batten, Prof. Victor Horsley, and Prof. Sherrington.

HARVEIAN SOCIETY.—Clinical Evening.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich-road, S.E.).—8.15 P.M. Discussion on Anæmia.

FRIDAY (5th).—WEST LONDON MEDICO-CHIRURGICAL SOCIETY (West London Hospital, W.).—8 P.M. Clinical Evening. The following cases will be shown:—Mr. Keetley: (1) Congenital Dislocation of Hip after Operation; (2) Sarcoma of Male Breast.—Mr. Bidwell: (1) Operation for Extensive Epithelioma; (2) Gastro-jejunostomy.—Dr. S. Taylor: (1) Congenital Spastic Paraplegia; (2) Bell's Palsy in a Child; (3) Hydrocephalus surviving to Puberty.—Dr. Clippingdale: Congenital Ichthyosis.—Dr. Chapman: Thoracic Aneurysm.—Dr. Potter: Tumour of the Upper Jaw.—Mr. McA. Eccles: Patient after Removal of Tumour of Upper Jaw.

SATURDAY (6th).—MEDICAL SOCIETY OF LONDON.—7 P.M. Anniversary Dinner at the Whitehall Rooms, Hôtel Métropole.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (1st).—ROYAL COLLEGE OF SURGEONS.—5 P.M. Mr. W. G. Spencer: The Pathology of Lymphadenoid Structures (Spleen, Lymphatic Glands, Bone Marrow). (Erasmus Wilson Lecture.)

LONDON POST-GRADUATE COURSE.—London Throat Hospital, Gt. Portland-st., W., 8 P.M., Mr. G. C. Wilkin: Nasal Polypi.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.)—5 P.M. Dr. Ball: Throat Cases.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Dr. A. Newsholme: Nature of Nuisances, including Nuisances the abatement of which is difficult.

SOCIETY OF ARTS.—8 P.M. Mr. C. F. Cross: The Industrial Uses of Cellulose. (Cantor Lecture.)

TUESDAY (2nd).—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Craig: Stupor, Katatonia, Dementia and Senile Insanity.—Hospital for Skin Diseases, Blackfriars, 4.30 P.M., Dr. Payne: Eczema, its Treatment.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—4 P.M. Dr. D. Grant: The Diagnosis and Treatment of the forms of Tinnitus Aurium.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Dr. Ormerod: Clinical Lecture on Tabes and Allied Cases.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM (73, Welbeck-street).—4 P.M. Dr. H. Campbell: On Cases of Peripheral Neuritis.

ROYAL INSTITUTION.—3 P.M. Prof. A. D. Waller: Animal Electricity.

SOCIETY OF ARTS.—8 P.M. Mr. M. Webb: Gesso.

WEDNESDAY (3rd).—ROYAL COLLEGE OF SURGEONS.—5 P.M. Mr. W. G. Spencer: The Pathology of Lymphadenoid Structures (Spleen, Lymphatic Glands, Bone Marrow). (Erasmus Wilson Lecture.)

LONDON POST-GRADUATE COURSE.—Parkes Museum, Margaret-street, W., 4.30 P.M., Prof. A. Wynter Blyth: House Drainage.

HOSPITAL FOR CONSUMPTION, &c., (Brompton).—4 P.M. Dr. H. Mackenzie: Bronchiectasis.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—3 P.M. Mr. F. Ruddle (conducted by): Inspection and Demonstration at L.C.C. Common Lodging House, Parker-street, Drury-lane (number limited).

SOCIETY OF ARTS.—8 P.M. Mr. G. Gordon: English Orchards.

THURSDAY (4th).—LONDON POST-GRADUATE COURSE.—Brit. Inst. of Preventive Medicine, Gt. Russell-st., W.C., 3.30 P.M., Dr. Allan Macfadyen and Mr. A. G. Foulerton: Separation of Proteid Substances occurring in Urine.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Dr. C. T. Williams: Clinical Lecture.

SOCIETY OF ARTS.—8 P.M. Prof. J. A. Ewing: The Mechanical Production of Cold. (Howard Lecture)

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—8 P.M. Dr. J. F. J. Sykes: Objects and Methods of Inspection.

ROYAL INSTITUTION.—3 P.M. Prof. P. Gardner: Greek History and Extant Monuments.

WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. Cheatle: Organisms which Infect Wounds.

FRIDAY (5th).—ROYAL COLLEGE OF SURGEONS.—5 P.M. Mr. W. G. Spencer: The Pathology of Lymphadenoid Structures (Spleen, Lymphatic Glands, Bone Marrow). (Erasmus Wilson Lecture.)

LONDON POST-GRADUATE COURSE.—King's College, 3 to 5 P.M., Prof. Crookshank: Anthrax and Malignant Œdema.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3.30 P.M. Mr. Gunn: Lecture.

THE CANCER HOSPITAL (FREE) (Fulham-road, Brompton, S.W.).—4 P.M. Mr. F. Bowreman Jessett: On Hysterectomy.

ROYAL INSTITUTION.—9 P.M. Mr. S. Bidwell: Some Curiosities of Vision.

SATURDAY (6th).—ROYAL INSTITUTION.—3 P.M. Right Hon. Lord Rayleigh: Electricity and Electrical Vibrations.

THE SANITARY INSTITUTE (Parkes Museum, Margaret-street, W.).—3 P.M. Mr. C. J. Kilgallin (conducted by): Inspection and Demonstration at the Marylebone Stoneyard, Richmond-street, Edgware-road, W.

METEOROLOGICAL READINGS.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND, WHEN ACCOMPANIED BY BLOCKS, IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

A ROD FOR QUACKERY.

ALL sensible people will sympathise with the sentiments of an admirable letter which appeared recently in the *Belfast News* from the pen of Mr. John Jellie of Carrickfergus. His contention that nowadays "men and women of ordinary intelligence have less excuse for swallowing quack prescriptions in the indiscriminate way of their ancestors of fifty years ago" is excellently written and supported.

Puzzled.—There is nothing whatever to be said against the institution. The members are allowed to employ any medical man they choose at terms which seem to us quite reasonable, having regard to the class of people who would join as *beneficiares*. The medical man is thus neither sweated nor pitted in unfair competition against his professional brethren.

THE RESURRECTION OF A NEEDLE.

To the Editors of THE LANCET.

SIRS,—On the 18th inst. a very stout man, aged thirty-five years, complained of a pricking sensation in the lower part of the abdomen. On examination a long, thin substance was felt under the skin lying transversely three inches above the pubes and one inch to the left of the middle line. Under chloroform this was easily removed, and proved to be an entire needle, moderately thick, and one and a half inch long. It was quite black and rusty in patches. The only history available was that when the patient was twelve years old he was said to have swallowed either a needle or a pin. Is it possible that such a foreign substance could have remained in the soft parts of the body for twenty-three years without causing any inconvenience?

I am, Sirs, yours faithfully,

EDGAR ELLIOTT, M.R.C.S. Eng., L.R.C.P. Edin.

Wolverhampton, Feb. 21st, 1897.

Inquirens.—A retired medical man is not generally charged by his medical attendant, and the same courtesy is usually extended to his family residing with him. But a point of etiquette may be too much insisted upon, and where the attendant is a poorer man than his retired brother professional, or where much medical attendance is required, it is our feeling that fees—some fees, if not full fees—should be paid. There is no obligation whatever upon the medical man to attend a curate gratuitously, though many practitioners are happy to do so.

J. B.—We can quite understand our correspondent's feelings, but we do not think it would be advisable to open our columns to possible correspondence upon matters of so personal a nature.

A SCOTTISH DULCAMARA.

A CASE with a most wholesome result was heard before the sheriff of Glasgow upon Feb. 18th. John Sutherland, calling himself a physician and surgeon, pleaded guilty to having during the months of October, November, and December, 1896, and January, 1897, in Glasgow or elsewhere in Scotland, wilfully and falsely pretended to be a physician, &c.

Mr. R. P. Lamond, writer, who appeared for the prosecutors (and to whom we are indebted for an account of the proceedings), the Scottish Branch of the General Medical Council, said the complaint was one brought—firstly, under the Medical Act of 1858 against a man who pretended to be a doctor of medicine, a surgeon, and a qualified medical practitioner, or alternatively at common law, falsely and wilfully impersonated his deceased uncle, Daniel Sutherland, who was at one time a registered medical practitioner, and who was struck off the roll by order of the Medical Council for conduct disgraceful under the Medical Act. Respondent, he might add, both published pamphlets and advertised to the effect that he was Dr. Daniel Sutherland, whereas his name was John. In reply to some innocent party who communicated with him he wrote, upon paper of his deceased uncle:—

"October, 1895. Dear Sir,—Your favour to hand and I am much obliged. I herewith forward to you a copy of my little pamphlet. I will be very happy to take you under my professional care, and from my extensive experience in all private complaints you may rely upon being perfectly and permanently cured in a very short time. "With best wishes, I am,

"D. SUTHERLAND."

The agent for respondent stated that the late Dr. Daniel Sutherland came to Glasgow from Edinburgh some sixteen or seventeen years ago to practise the profession there. His nephew, John Sutherland, was his assistant for about fourteen years prior to his death. He became executor to the estate after his uncle's death, and thought there would be no harm if he continued to carry on the business in the same manner.

"The sheriff characterised the offence as a very serious one. Respondent had had no medical training or medical education. He knew nothing about the matter except what he might have picked up in the course of assisting Dr. Daniel Sutherland. It was bad for him to say he was Dr. Sutherland, but it was a great deal worse for a person in his position, who probably knew nothing about medicine or medical matters, to take advantage of the weakness and folly of individuals, and profess to deal with diseases of a serious character. He had no hesitation in imposing a penalty of £15 15*s.* and £10 as the expenses of the prosecution."

These remarks of the sheriff are eminently just and satisfactory, but we cannot help thinking that the penalty for frauds of this description is not half heavy enough. The man who pretends to be in possession of degrees or qualifications implying that he has undergone a definite course of instruction, and who by this implication deludes people into the belief that he knows how to treat diseases, is neither more nor less than a potential murderer. So also is the adulterator of food and the seller or consigner of bad meat. People of this description make enormous profits, and, if fined at all, should be mulcted in hundreds, not in tens.

Variola and R. L.—We do not think any useful purpose would be served by prolonging the correspondence.

"THE UNQUALIFIED ASSISTANT."

To the Editors of THE LANCET.

SIRS,—With the arguments of "One of the 'Dawdlers'" it is not worth while to deal. They neither support the contentions of "Student" (THE LANCET, Dec. 19th, 1896) nor traverse any of my statements in reply to those contentions. With the sarcasms and personalities, which constitute by much the larger part of your correspondent's long letter, I decline to deal.

I am, Sirs, yours faithfully,

Feb. 23rd, 1896. A PRACTITIONER.

Alpha.—The pursuit would be particularly bad for the complaint, and we cannot think that any saddle would obviate the harm.

NOT RIGHT.

WE have received a specimen of a large poster which is being exhibited in Brighton under the auspices of the local centre of the St. John Ambulance Association. In a prominent place are the names of the executive committee, with their addresses, and among them we notice those of four local medical men, three of whom have their qualifications appended as well. We do not think it desirable that medical men should have even their names and qualifications placarded like this, but the addition of the addresses is unpardonable. Doubtless the poster was issued without the knowledge of the gentlemen in question, but, at any rate, we appeal to their sense of what is fitting for members of the medical profession to stop such an unseemly display.

Hosted by Google

A NORTHERN DOGBERRY.

MR. BEILBY is a superintendent of the North Riding Constabulary and he also gave evidence upon Feb. 23rd before the Royal Commission on the Liquor Laws. He said that the *bonâ-fide* traveller in his district caused the police a great deal of trouble, which we can well believe, and he was of opinion that the "traveller clause" ought to be expunged from the licensing laws. He did not think that the "traveller" evil would be diminished by increasing the three mile limit to seven or eight miles: the only thing for it was abolition or the adoption of a plan of this kind—"that a person going into the country on a Sunday should present himself at police headquarters, state his destination, and obtain an official permit to obtain refreshment. Of course, the police would discriminate between respectable persons and parties who presented themselves in red handkerchiefs and clogs, and were accompanied by terrier dogs." This plan, we think, would give the police an infinity of trouble and we do not see how it would work. There is nothing to prevent any publican from serving a man who had not got a ticket except by having a corps of *agents provocateurs*, and that system is not regarded with favour by the majority of the British people. It has always seemed to us that the real way to lessen drinking is to increase the punishment for it. If a man gets so drunk as to be a nuisance to his neighbours or has to be taken to a hospital to be revived he should be heavily punished. At present, unless he commits an assault, he can give infinite trouble to numbers of people and get off scot free. People will drink and no one can prevent them, but the consequences of getting drunk should be made as disagreeable as possible.

L. N.—Another, in fact more than one other, correspondent has already employed the *non de plume*. Our opinion is an opinion, not a decision. L. N.'s guardians have used their discretion and decided one way. The Local Government Board, we are sorry to say, reads the Act differently.

"ANTISEPTIC MIDWIFERY."

To the Editors of THE LANCET.

SIRS,—In your last number Mr. Harding, writing on Antiseptic Midwifery, quotes me as recommending the following solutions:—

Carbolic acid, 1 in 50.
Tincture of iodine in water—to a sherry colour.
Condy's Fluid, 1 in 80.
Perchloride of mercury, 1 in 2000.

Permit me to say that this was taken from an old edition of my work on Midwifery, published eleven years ago, and that there is not one of them which I should recommend now as a thoroughly reliable antiseptic. The more recent experience of lying-in hospitals has conclusively shown, I think, that the only antiseptic to be thoroughly relied on for the purification of the hands is a 1 in 1000 solution of perchloride. This, however, is too strong for vaginal injections, or for ablutions of the genitals. For these purposes, I think, the best antiseptic is a solution of creoline in water, which can be conveniently carried in a concentrated liquid in the obstetric bag in the form of Jeyes' "Liquor Antisepticus." The perchloride solution is also injurious to forceps and other metallic instruments. They can best be purified by boiling, or by thorough heating in the flame of a spirit lamp, and subsequent immersion in the creoline solution, which also acts as a lubricant. Tincture of iodine, dropped into water, still finds a useful application in the exceptional cases in which it is found to be necessary to wash out the uterine cavity.

I am, Sirs, yours faithfully,
Grosvenor-street, W., Feb. 18th, 1897. W. S. PLAYFAIR.

C. G. H.—1. It has been hitherto a general rule, but it is a matter of feeling rather than of etiquette. There is, of course, no legal obligation. If the interests of the profession and those of nursing become antagonistic the rule may fall into disuse. 2. If the rule is to be generally obeyed it should cover most special cases, and the fact that the patient is not resident in the town should make no difference. 3. If the rule is not generally obeyed a special exception might well be made in favour of those resident in town. Such attendance, we think, should be given gratis.

Transfer.—See "Form of Deed for the Assignment of a Medical Practice" in Chapter iii. of "Medical Partnerships, Transfers, and Assistantships," by Mr. William Barnard and Mr. G. Bertram Stocker (Stevens and Sons, 119 and 120, Chancery-lane, London). The Form of Deed in its various developments occupies sixteen pages in this book. The stamp duty would probably be ½ per cent, or £3 15s. for £750.

Sister Julia Tudor.—No amount of contradiction would alter so prejudiced a person's views. He has not the special knowledge to enable him to understand wholly the scientific side of the things he writes about, and those who do understand such matters prefer to let him alone. He has not described what he saw so much as what he thinks he saw.

FOOTLIGHT PHYSIOLOGY.

VEGETARIANS have hitherto been regarded as the most self-denying of mortals in the matter of food, but a new prophet has arisen and it behoves them to look to their laurels. The immortal Hiya, or She-who-must-be-obeyed, enunciated the aphorism, "Fruit is the only true food for man"; and now we have Miss Loie Fuller, the *danseuse*, declaring, through the medium of an illustrated paper, that the sole way to prolong life like the patriarchs of old to a hundred years or more is by becoming strictly frugivorous. Skirt-dancing is scarcely an occupation calculated to develop or foster asceticism in any form, but the fact remains that one of the most talented exponents of the pastime has made her appearance as an uncompromising denouncer, not only of animal food in general, but even of edibles containing starch. "We are governed by custom, whereas we ought to be led by the promptings of nature," cries this fervent disciple of Plato in her exordium, and then with some inconsistency proceeds to the solemn warning, "We are slaves to the palate, let us strive to become its master." That Miss Fuller's physiology is as novel as it is ingenious the following example will show: "The sugar in the sweet fruits serves the same end as starch in other things. Starchy substances must change first into dextrine and then into glucose ere they reach the stage dates and figs have already attained. The ripening process has brought them to the condition whereto starch is reduced in the human body. On this development nerve force is exhausted, and the tissues are gradually weakened, all which may be avoided by replacing starchy foods with naturally sweetened ones." In fact, the entire article is brimming over with learning, but, alas! that we should have to say so, it is the kind of learning against which Pope warns us.

Enquirer.—Alterations having recently been made in the Canadian medical curriculum we think that our correspondent's wisest course would be to communicate directly with the authorities in the colony. It would be best to graduate at the McGill University, Montreal, or Toronto University. Details concerning the fees to be paid and the dates of the examinations can be obtained from the deans of the medical schools at either institution.

A RARE CASE.

To the Editors of THE LANCET.

SIRS,—The following case is of interest owing to its rarity. In several hundred midwifery cases, with their endless variety, I have never met with, nor can I find, a similar one on record. On Feb. 8th I was called to attend Mrs. ——, a young primipara, who had been in labour about nine hours. Digital examination discovered a large, soft mass on the external genitals. I at first thought this was an abnormally large bunch of varicose veins, but on inspection found it to be anasarca extending on both sides of the vulva, from the pubes to the anus, being over three inches in breadth and so deep that the index finger was completely covered before it could enter the vagina, and this was only accomplished with considerable pressure. The anasarca entirely disappeared in eight days. The patient had no sign of any œdema elsewhere and her urine was free from albumin.

I am, Sirs, yours truly,
Midhurst, Feb. 22nd, 1897. A. E. PETERS.

W. B. G. writes as follows:—"W. H., farmer and carrier, club patient, paying 3*s.* 6*d.* per year, under my care six months, case purely surgical, inflamed bone and abscesses, visited seventy-five times, travelling 300 miles, had two consultations over the case. Am I entitled to fee for consultations? W. H. refuses to pay?"—We fear our correspondent has no remedy. The patient, of course, should not be a club patient. But being one, and accepted as such, he has contracted himself out of all his honourable obligations and can claim any amount of our correspondent's attendance that he may require.

A MODERN MINERVA.

THE following verses have been sent us by a correspondent, who does not say whence he obtained them:—

"She is fair in form and feature, quite an airy, fairy creature, and of art a leading teacher; she can talk and play and sing, too, in a manner quite divine.

"She contributes to THE LANCET, can survey with chain and transit, name a dance and she can dance it, and in golf and tennis playing she is always first in line.

"She can act as well as Sarah, that dramatic 'avis rara,' she is what all folk declare a very wonderful young lady who has wisdom without stint.

"She is versed in Greek and Latin, paints on canvas, plaques, and satin; quoting poetry she's pat in; but she cannot bake a biscuit that is half as soft as flint."

We appear to have been entertaining an angel unawares.

Sceptical.—No such name as H. S. Schultess-Young, M.D., appears in the current Medical Register.

An Inaugural Address

ON

THE UNDIMINISHED MORTALITY FROM PUERPERAL FEVER IN ENGLAND AND WALES.

Delivered before the Obstetrical Society of London on March 3rd, 1897,

BY CHARLES J. CULLINGWORTH, M.D. DURH., F.R.C.P. LOND.,

PRESIDENT OF THE SOCIETY; OBSTETRIC PHYSICIAN AND LECTURER ON MIDWIFERY AND DISEASES OF WOMEN, ST. THOMAS'S HOSPITAL.

GENTLEMEN,—Notwithstanding the risk of repeating what every newly elected President has said before when rising for the first time to address those to whom he owes his distinction, I cannot let such an opportunity pass without expressing my sense of the honour you have conferred upon me in calling me to occupy this responsible position. It is no mere empty form of words when I say that I enter on my duties with diffidence and a keen sense of the responsibilities I am undertaking. I sincerely trust that my term of office may be one of prosperity and peace, and I think there is every probability that it will be. But whether it should be my good fortune, whilst in command of the vessel, to have prosperous winds and a calm sea, or whether it be otherwise, you may rely on my doing my utmost to follow the best traditions of the society, to uphold its dignity and interests, and to help it to fulfil the great objects for which it was founded and which it has hitherto so faithfully and successfully carried out. I have sometimes thought that the society suffers from a plethora of presidential addresses. It is the custom for every President to deliver three addresses during his two years' tenure of office—viz., an inaugural address, a valedictory address, and a sort of interim report at the close of his first year of office. One consequence of this arrangement is that every second year it happens, as on this occasion, that the time of the society is occupied at two successive meetings by an address from the chair. It is conceivable that such an arrangement might come to be a serious interruption to the ordinary business of the society, though at present the list of communications in the hands of the secretaries is not a long one.

Perhaps the most usual conception of the function of an inaugural address is that it should embrace a survey of recent progress. My own notion is that it should be regarded as an opportunity to give utterance to thoughts, bearing on the society's objects and work, that have been occupying the speaker's own mind and that are of too general a nature to form the subject of an ordinary communication. Retrospects of the kind just alluded to undoubtedly have their uses, but, besides their tendency to become monotonous, they have to my mind this additional drawback—that they concentrate our attention too exclusively upon the bright side of the picture and miss the lessons to be learnt from our disappointments and failures. Presidents of scientific societies are not singular in this habit of recording successes, and ignoring or passing lightly over the failures. It is the tendency of human nature in general, and presidents of scientific societies, notwithstanding all the dicta of Miss Cobbe and her coterie to the contrary, are very human.

I cannot help thinking, however, that it must be a good thing to have our attention called, at least once now and then, to the darker and more disheartening aspect of affairs, to be brought face to face with the actual facts of the situation, so that, recognising our errors, we may endeavour to repair them, and, having our weak places pointed out, we may set to work to strengthen them, and that we may be stimulated to gird ourselves with new and more serviceable weapons for the struggle in which we are severally engaged. In our own profession it has passed almost into a proverb that there is often more to be learnt from a record of failure than from a story of success. It is from a strong conviction of the truth of this that I have decided to utilise this occasion for the purpose of drawing the attention of the profession to the death-rate from puerperal fever in this country, and to the humiliating fact that, notwithstanding the introduction of antiseptics, the almost complete banishment of the disease from our lying-in hospitals, and the general advance in our obstetrical knowledge, the death-rate has not only not diminished, but in some districts has actually increased during the past few years. Attention has already been called to this fact by others, especially by Dr. Boxall[1] and by Dr. Williams of Cardiff,[2] to whose valuable papers I am indebted for much of the information I am about to bring before you. But there seems good reason to think that the profession has not as yet realised the enormous importance and significance of the facts to which these writers have invited attention, and has not by any means laid to heart the lessons to be learnt from them or the urgent necessity that exists for a radical alteration in our present midwifery practice. It appears to me that at the present moment there is no obstetrical or gynæcological subject that can compare in importance with this question of the undiminished death-rate from puerperal fever.

Three or four years ago Dr. Boxall was appealed to by a physician to one of the insurance companies for facts bearing on the alleged diminution in the mortality of childbirth. The directors of the company were considering how far they would be justified in relaxing the rule by which 1 per cent. had hitherto been added to the insurance premium in the case of women expecting their first confinement. The result of the inquiry instituted by Dr. Boxall, in response to this appeal, proved startling even to himself. It was well known that the mortality from puerperal fever had during the past few years diminished almost to the vanishing point in the lying-in hospitals, and the knowledge of this fact had led to the impression that the general mortality from puerperal fever had diminished. Indeed, it had so far come to be taken for granted that speakers and writers on the subject repeatedly referred to this alleged diminution as a matter of common knowledge and as an occasion for legitimate jubilation. When the returns of the Registrar-General came to be examined, however, it was found that this rejoicing had been premature. The figures showed that, so far from having diminished, the death-rate from puerperal fever in England and Wales had considerably increased. The mortality returns of the Registrar-General are arranged under two headings—viz, (1) puerperal fever or metria, and (2) accidents of childbirth. The latter includes cases fatal from hæmorrhage, eclampsia, puerperal mania, pulmonary embolism, &c. Deaths occurring during childbed from pre-existing disease or from causes not directly connected with childbirth, though taking place during labour or during the lying-in period, are left out of account. The returns under the two headings mentioned, therefore, comprise all the deaths known to have occurred *from* childbirth, though not all that occurred *in* childbirth. I am not concerned on this occasion with the mortality from the accidents of childbirth, though I may have to allude to them incidentally. My purpose is to call attention to the deaths from puerperal fever.

In the accompanying table is shown in detail the actual

TABLE I.—*Showing Mortality from Puerperal Fever in England and Wales from 1847 to 1895.*

Year.	No. of deaths.	Per 1000 births.	Year.	No. of deaths.	Per 1000 births.	Year.	No. of deaths.	Per 1000 births.

[1] The Mortality of Childbirth, THE LANCET, July 1st, 1893.
[2] Puerperal Mortality, Transactions of the Epidemiological Society, March, 1896.

Hosted by Google

number of deaths returned annually under that head from the year 1847 to 1895 inclusive, together with the death-rate estimated in relation to the number of registered births—that is, to the number of children born alive.

It will be seen that in 1881 there was a rise both in the actual number of deaths and in the percentage. It is quite true that the figures of that year had been exceeded on two occasions previously—viz., in 1874 and 1875; but after those two years the figures fell again, whereas since 1881 the increase has been maintained. It is this which gives significance to the rise in 1881. It should, however, be mentioned that in that year, with a view to making the returns more complete, the Registrar-General, in certain cases in which the certificates of death were not satisfactorily filled up, wrote to the medical men who had signed them for further particulars. Thus a letter was sent in every case in which a woman of child-bearing age was stated to have died from either peritonitis, septicæmia, or pyæmia. As a result of these special inquiries, which have been continued to the present time, numerous deaths have been added under the heading of puerperal fever. I am perfectly willing to make full allowance for this and to concede that the sustained increase in the mortality from puerperal fever during the last fifteen years is to be partly accounted for in this way. But when all this has been granted we are still face to face with the fact that the mortality has not appreciably diminished during the past fifteen years, and that the year 1893 was conspicuous for a puerperal fever mortality only once exceeded since 1847, the year in which the Registrar-General first issued a separate return. It is not pretended that the Registrar-General's returns give the figures with absolute correctness. No system that depends upon the accuracy of statement of a large number of people ever can be perfect. Besides which, as I have elsewhere pointed out, there is a natural tendency on the part of medical men, partly on personal and partly on public grounds, to avoid attributing deaths directly to the effect of childbirth. If, however, the figures err, they err in the direction of being *below* the truth, not *in excess* of it. Moreover, the sources of fallacy are not limited to a single year; they are the same throughout a long series. Hence they do not affect the comparison of one year with another, which is what I am now chiefly concerned with. Indeed, there can be no doubt that, if we could obtain perfectly correct returns, they would bring out even still more strongly the point to which I am directing attention, for while the number of deaths and the percentage would both be higher the comparability of the figures of any one year with those of other years would remain unaffected.

Before proceeding to inquire into the causes of the persistently high mortality from puerperal fever it may be well to ask your attention for a few minutes to its geographical distribution. In London the total death-rate from childbirth has considerably diminished. The diminution is due, however, not to any appreciable lowering of the mortality from puerperal fever, but to a lessened mortality from the accidents of childbirth. In the provinces, on the other hand, the total death-rate from childbirth remains practically unaltered; but whilst, as in the case of London, there has been a diminution in the mortality from the accidents of childbirth, the mortality from puerperal fever has increased to such an extent that instead of being accountable for less than a third of the total mortality it is now accountable for more than one-half. In a paper read before the Epidemiological Society in March of last year (1896) Dr. Williams, the medical officer of health for the county of Glamorgan, showed that, of the various districts and counties of England and Wales, those with the heaviest death-rate from puerperal fever between the years 1848 and 1894 were Lancashire (2·4), which heads the list, North and South Wales, Northumberland, and Cheshire (2·2). Close behind them came Cumberland, Durham, the West Riding of Yorkshire, Derby, and London (2·1). Surrey had the lowest mortality, and very near to it came Cornwall, Sussex, Hants, Dorset, and Rutland (all under 1·4). Taking the shorter and more recent period embraced between the years 1885 and 1894, Lancashire, Cheshire, and North and South Wales still maintain their unenviable pre-eminence in the black list; Northumberland disappears from it; and Derbyshire and the West Riding of Yorkshire take its place. Dr. Williams points out that as a general rule the rate is "highest in the Western Counties, especially in the hilly Welsh division, or, roughly, in those counties and parts of counties west of a straight line drawn from the mouth of the Severn to that of the Tees."

It would be impossible in the limited time at my disposal this evening to enter into a detailed inquiry into the conditions of life and other circumstances which might serve to explain the relative mortality from puerperal fever in all these various districts. It must suffice if I select one district—namely, that of Wales. I make this selection because in the paper already alluded to Dr. Williams has furnished, ready to our hands, very ample materials for forming an estimate of the determining causes of the high death-rate from puerperal fever in that part of the country. After giving a table of the death-rate for each Welsh county for a period of ten years, Dr. Williams observes that density of population does not seem to be "a factor of much importance in determining puerperal mortality; on the contrary, both the mortality from puerperal fever and from accidents of childbirth display a marked tendency to prevail in those counties where the only features in common between them is that they are mountainous, hilly, and sparsely populated, and that consequently locomotion is tedious and medical assistance difficult to obtain in time. On the other hand, the mortality seems to be generally lowest in the flatter counties." He then proceeds to speak more particularly of the registration county of Glamorgan, of which, as the medical officer of health, he has an intimate knowledge. The county of Glamorgan "has an estimated population of some 800,000, over half the population of Wales. It covers 516 966 statute acres, and includes the two county boroughs of Cardiff and Swansea." The county is divided into eight registration districts, and it is instructive to follow Dr. Williams in his summary of the relative mortality from childbirth in each of these and the conditions of life that prevail in them. In the Cardiff registration district the puerperal mortality exactly corresponds with the mean for England and Wales (2·0 per 1000 births). "Its sanitary condition is satisfactory, and confinements are attended generally by the medical men and trained midwives." In the Pontypridd district the puerperal mortality is excessive (4·1). Its sanitary condition is generally unsatisfactory, and most of the confinements are "attended by untrained midwives." In the Merthyr Tydvil district the death-rate from puerperal fever is higher than in any other district in Wales—viz., 4·7 per 1000 births. The greater number of confinements are attended by midwives, of whom only a few, if any, are trained. As to its sanitary condition, although that of Merthyr itself is highly unsatisfactory, that of the other parts of the district is fair. In the next district on the list—that of Bridgend—the mean annual mortality from puerperal fever for the past ten years closely approaches that of the Merthyr Tydvil district, being 4·5 per 1000 births. This district includes one small town, a small seaside resort, four mining valleys, "and an extensive rural district with an agricultural and mining population." In the mining valleys the greater number of colliers' wives are attended by unskilled and ignorant midwives, none of whom are trained or registered. The sanitary condition of the district is in some localities exceedingly unsatisfactory. In the Neath registration district there are five towns with a population varying from 4000 to 12,000, "together with an extensive area studded with mining villages and farmhouses. In the mining valleys many confinements are attended by midwives, but in the towns only a few comparatively. The sanitary condition is fair." The death-rate from puerperal fever in this district is very variable. The mean annual rate for the ten years ending 1894 was 2·8 per 1000 births—that is, higher than that of the Cardiff district, but much below that of the other three districts already mentioned. In the Pontardawe registration district, containing three mining and tin-plate towns, skilled medical assistance can be procured at short notice. The puerperal fever mortality is low (1·6). The Swansea registration district, besides the town of Swansea, includes a scattered mining population. The sanitary condition is unsatisfactory and midwives are employed to a considerable extent. The death-rate from puerperal fever is fairly high (3·0). In the Gower registration district, which is largely agricultural, the sanitary condition is fair, but the rate of mortality from puerperal fever is high (3·8). Dr. Williams points out that as regards the towns the puerperal fever mortality is much the same as in similar towns elsewhere. In the densely populated mining valleys, on the other hand, the mortality is exceedingly high. He attributes this in a great measure to the systematic employment of unskilled and ignorant mid wives. "From my experience in Glamorgan," he says, "I can prove without a doubt that they often spread puerperal fever broadcast, and are often not interfered with." "The

Hosted by Google

conditions of life," he continues, "consequent upon the physical features of the country, especially in North Wales, often make it impossible to obtain skilled assistance in time; and if any [assistance] is to be obtained it must be from untrained midwives." Even these are not always available, for in such districts friends and neighbours are often compelled to give the help that is needed.

I have considered the case of Wales at some length because the information at our command is so definite. No one, I think, after hearing the above facts, can have any doubt as to the causes which mainly determine the excessive death-rate from puerperal fever in that country. I have not time, as I said before, to inquire at any length into the conditions of life amongst the working classes in all the districts in which the mortality from puerperal fever is excessive, but I cannot refrain from saying a word or two about Lancashire with regard to which we have some very important evidence. In the year 1892 Dr. T. E. Hayward, the medical officer of health for the district of Haydock, in Lancashire, appeared before the Select Committee on Midwives' Registration. The following is an abbreviated extract from the minutes of his evidence: "Haydock is a coal-mining district. The population is 6535; there were 272 births registered last year; the average number for the past few years is 250. ..... I am in a position to state that scarcely a fifth part of those confinements are attended at any stage by a doctor. The work is done by women who practise as midwives," but who "are, with few exceptions, untrained and in very many cases grossly ignorant and incompetent." "The same condition of things holds good more or less in the whole of that part of Lancashire." In support of that statement he quoted the report of the medical officer of health for the county borough of St. Helens, with a population of over 70,000, in which it was stated that the great majority of confinements in St. Helens "are attended by midwives, a large number of whom have no other qualification than that of being mothers themselves." It will thus be seen that, at least in one important particular, the conditions under which the death-rate from puerperal fever is excessive in Lancashire are similar to those which prevail in Wales. It must not, however, be supposed that I am going to lay the entire blame for the present deplorable loss of life from puerperal fever upon the midwives. The evidence is incontestable that they are responsible for much of it, but on this head I have probably for the present said enough. I desire now to bring the inquiry nearer home.

By the kindness of Mr. Shirley Murphy, the medical officer of health for the administrative county of London, I have been supplied with a statement of the number of cases of puerperal fever notified in the various parishes within the London sanitary district during the five years 1891–5, and also with a statement of the number of births in each parish during the same period. From these two statements I have been enabled to draw up a list showing the number of notified cases of puerperal fever to every thousand births in each of the forty-one parishes. In other words, I have constructed a table of the relative incidence of puerperal fever in the London sanitary district during 1891–5. The result, which is somewhat unexpected, has been embodied in a map of the district, prepared for me by my friend Mr. R. E. Holding. In this map the parishes where puerperal fever is most prevalent are shaded black, those in which the prevalence is a little below the highest, but still greater than in London taken as a whole, are marked by cross lines and dots, those in which the rate is less than that for the whole of London are marked by horizontal lines, while those in which the proportion of cases to the number of births is comparatively small are left white. Hampstead heads the list, for, although the actual number of cases is smaller than in many other parishes, the proportion of cases to the number of confinements (as estimated by the number of births) is the highest in London. As regards the actual number of cases Islington had by far the largest—viz., 169; next to it, though at a considerable distance, came St. Pancras with 88, Lambeth with 86, and Battersea with 84.

The parishes that figure in the black list, then, are Hampstead, Islington, Battersea, Wandsworth, and Lewisham. All these show a rate of over 3 cases per 1000 births. After them come, in the order named, Fulham, Paddington, Greenwich, St. James, Bethnal Green, St. Pancras, Hammersmith, Lee and Plumstead, Stoke Newington and Hackney, Kensington and Chelsea. The rate in all these is higher than that for London generally. It will be observed that Westminster, Lambeth, Whitechapel, St. George-in-the-East, and Shoreditch, which might have been expected to appear high up in the list, show a much smaller proportion of cases than Hampstead and Islington, and even St. James, Kensington, and Chelsea. In St. Martin-in-the-Fields not a single case was notified, while Bermondsey, St. George (Southwark), St. Olave, St. Giles, Strand, and St. Luke all show a remarkably small percentage. A comparison between this map and the map on which the parishes are shaded according to the number of persons to each acre clearly shows that the prevalence of puerperal fever is not proportionate to the density of population.

TABLE II.—*Showing the Relative Incidence of Cases of Puerperal Fever in the respective Parishes of the London Sanitary District from 1891 to 1895.* (*See Maps.*)

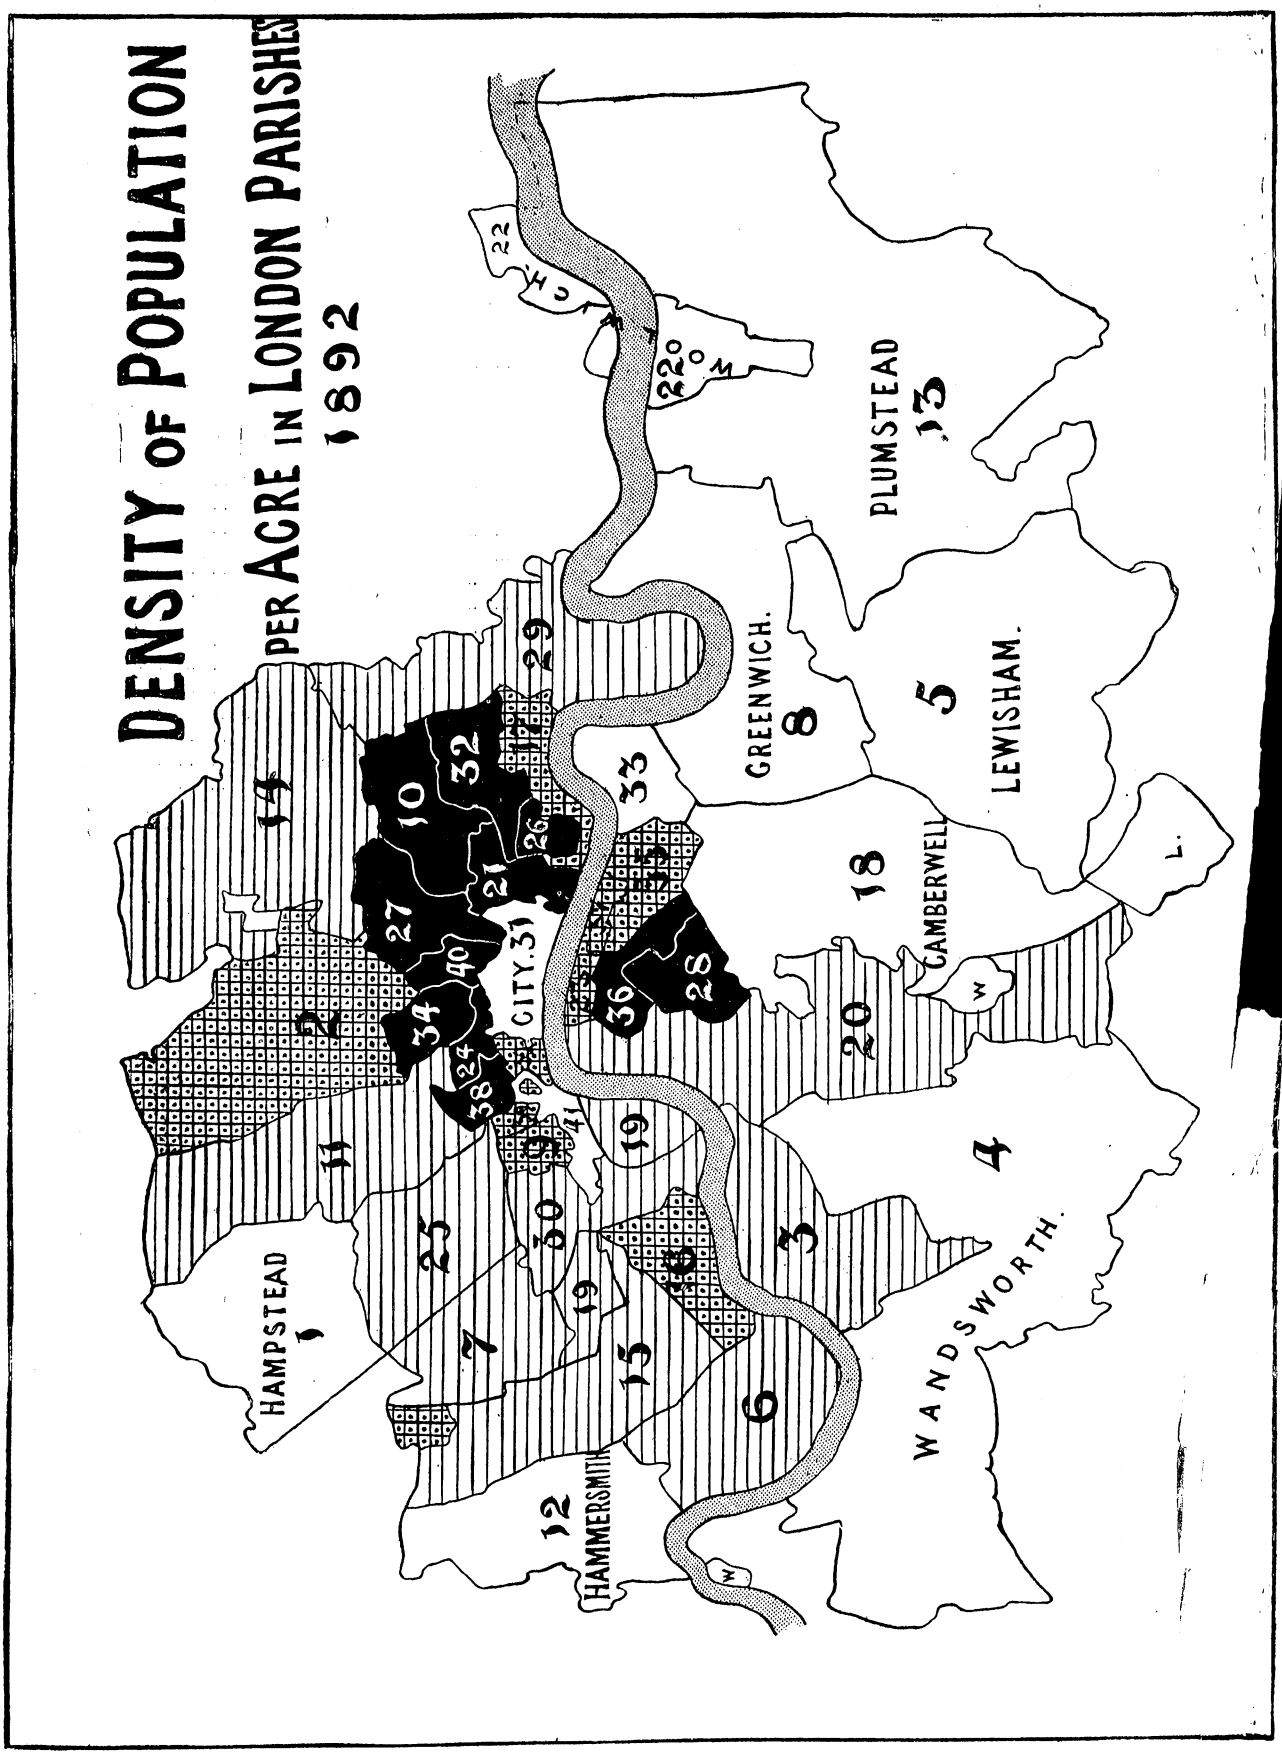
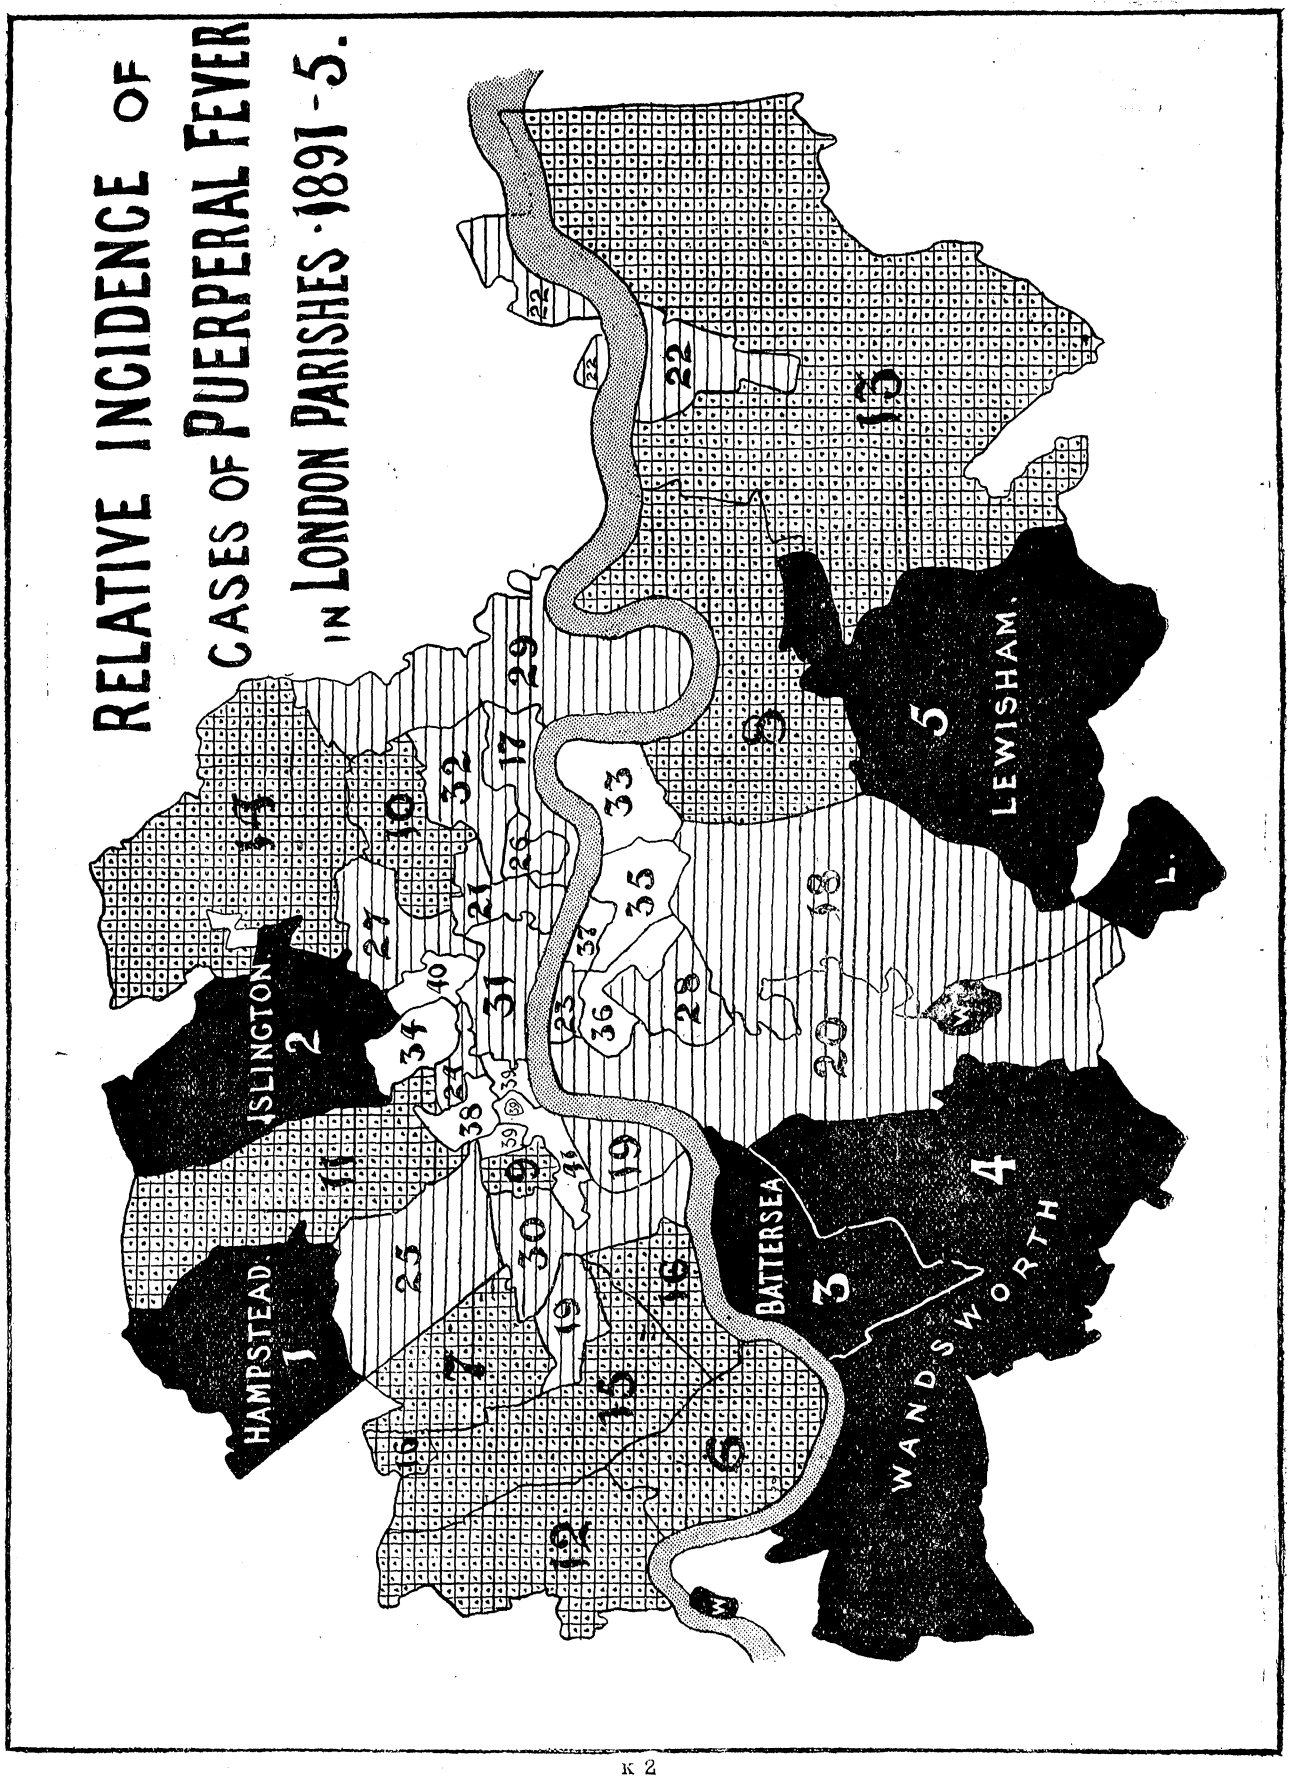
21	Whitechapel	1·86			



Rate for the whole sanitary district of London, 2·17.



The number of deaths recorded for the whole of London in the returns of the Registrar-General (1305) so nearly approximates the number of notified cases that it seems safe to infer that the cases notified were for the most part fatal, and that the result of the inquiry would not have been materially different if it had been based on the number of deaths in each parish instead of on the number of notified cases.

It is no part of my present purpose to inquire into the special conditions of the various parishes with a view to determining the causes of the greater prevalence of puerperal fever in one parish than in another. Such an inquiry would possess great interest and great value, but it would lead me too far afield this evening. I have alluded specially to the mortality in London in order to show that puerperal fever still claims its victims, not only in thinly-peopled country districts, but also in places densely populated, where, whatever the causes may be, the difficulty of obtaining medical assistance cannot be one of them. Although puerperal fever has practically become a thing of the past in our lying-in hospitals—witness the remarkable record of the General Lying-in Hospital and the equally remarkable results that Dr. Godson was able the other day to point to as having followed the introduction of antiseptics at the City of London Lying-in Hospital[3]—it is impossible to ignore the fact that there has not been a corresponding diminution of mortality from puerperal fever in ordinary private practice. It was not to be expected that those who had already been engaged for some time in practice would at once assimilate the new ideas and adopt what appeared to many of them not only new but revolutionary and unnecessary methods. But as time wore on

and a younger race of men came upon the scene it was not unnaturally hoped that an improvement would take place, and that a mortality which had been conclusively shown to be preventable would show some signs of diminution. How is it that this hope has not been realised? Either the profession is not convinced of the possibility of stamping out puerperal fever by the methods that have been proposed or it has failed to carry out those methods with the thoroughness that can alone ensure success. As a responsible teacher of midwifery I have often asked myself the question how far the teaching is at fault. Do we teachers sufficiently impress upon the minds of our students the infinite importance of this subject? Are we ourselves careful to show by our own example the importance of the precautions that we lay down in the lecture theatre? Are we careful never to convey, by thoughtless word or careless act, the impression that the rigid adoption of antiseptic measures is excellent in theory, but does not, after all, matter so very much in practice? If we are not, is it to be wondered at that when our students go out into the world and are released from the discipline of the school and hospital they should forget how much depends on attention to minute detail, and should discharge their consciences in this matter of antiseptics by pouring a few drops of carbolic acid or a drachm of tincture of iodine into the water in which they wash their hands, or even by simply bidding the nurse administer a similarly prepared solution as a douche? I am not painting an imaginary picture. The methods at present employed by many who if questioned would be quite ready to proclaim their belief in antiseptics, and who glibly assure one they have used "every antiseptic precaution," are often so crude and imperfect as to be a ludicrous travesty of genuine antiseptic midwifery.

The questions I have just been asking I ask of myself as well as others. It is clear that something is wrong. We shall be most likely to find out what that something is by a process of self-examination, both on the part of teacher and taught, however disagreeable that process may be. A great deal has been written on the superiority of asepsis as compared with antisepsis, and it has become the fashion in some quarters to speak of antiseptics as though they had had their day and to maintain that a condition of asepsis can be attained by cleanliness alone. It is well, however, to bear in mind that the triumphs of our lying-in hospitals have all been won by the scrupulous use of antiseptics, and that sterilisation, which is the essential element in aseptic surgery, is impossible in midwifery practice. When we have thoroughly washed our hands, as we all now recognise the necessity of doing before making an examination in the lying-in room, it costs very little trouble to adopt the additional safeguard of immersing them for a few moments in an efficient antiseptic solution. And as a matter of experience those who are most diligent in the use of antiseptics are also the most diligent in carrying out all the details of elementary cleanliness. I firmly believe that if the simple antiseptic precautions with which everyone is familiar were conscientiously adopted puerperal fever would be as rare in private practice as it is now in the best lying-in hospitals. "The only way," as I have elsewhere observed, "to avoid (the present) terrible mortality, and to avoid also the terrible amount of puerperal disease, which, because it is not fatal, is apt to remain unrecorded, is for every practitioner in midwifery to recognise his personal responsibility in the matter."

In an excellent little book of advice to mothers the writer, herself a woman, after doing me the honour to quote the foregoing passage, makes the following significant comment: "Now I maintain," she says, "that *women themselves* have a *personal* responsibility in this matter also. They should not be content passively to allow their lives to lie in the hands of others who may or may not choose to use antiseptics. Women who are expecting their confinements should satisfy themselves beforehand that the doctor and the nurse engaged to attend will conscientiously use these safeguards."[4] This is plain speaking, but who will be disposed to find fault with it? It will be gathered from what I have said this evening that, in my opinion, the high death-rate from puerperal fever in this country is attributable mainly to the large number of confinements attended by ignorant and untrained midwives and to laxity and half-heartedness in the use of antiseptic precautions in private practice. The remedy for the first of these evils is to insist that women who call themselves midwives shall possess at least such an elementary knowledge of the subject as shall enable them to know how to prevent septic infection. The remedy for the second evil is thoroughness.

It is now nearly nine years since I published, in the form of an introductory address at St. Thomas's Hospital, a plea for the more general adoption of antiseptics in midwifery practice.[5] In that address I brought together as concisely as possible the evidence that had been gradually accumulated in proof of the preventability of puerperal fever, and I showed in a series of tables the magnificent results that had followed the introduction of antiseptic measures into the leading maternity hospitals of Europe and the United States. I have reason to know that the arguments I then brought forward were not without effect upon the practice of individual members of the profession. I ought perhaps to apologise for returning to-night to a subject that may seem to many to have been long ago thrashed out. The temptation was indeed great to choose some newer topic for an occasion like the present. But the more I reflected on the matter the more it was borne in upon me that it was my duty once more to raise my voice on behalf of the mothers of this country. The Obstetrical Society of London has always been foremost in the effort to reduce the present terrible mortality from childbirth. It seemed to me that I could not more suitably signalise my succession to this chair than by calling attention to the sad and disappointing fact that has formed the text of this address. If anything I have said shall have the effect of stirring the minds of my professional brethren on this subject and of diminishing to ever so slight an extent the present terrible death-rate from a disease which is now generally acknowledged, nay, proved, to be almost wholly preventable, I shall feel that I have achieved something worthy of the occasion and have done something towards justifying your choice of a president.

The Erasmus Wilson Lectures

ON

THE PATHOLOGY OF THE LYMPHADENOID STRUCTURES.[1]

Delivered at the Royal College of Surgeons of England on March 1st, 3rd, and 5th, 1897,

BY W. G. SPENCER, M.S., M.B. LOND., F.R.C.S. ENG.,

SURGEON TO OUT-PATIENTS AND THROAT DEPARTMENT, WESTMINSTER HOSPITAL, AND LECTURER ON PHYSIOLOGY AT WESTMINSTER HOSPITAL MEDICAL SCHOOL.

LECTURE I.

Delivered on March 1st.

GENTLEMEN,—The organs composed of lymphadenoid tissue are the bone marrow, the spleen, the thymus, and the glands and follicles in the mucous membrane of the alimentary and respiratory canals, but new formations may also appear in connective tissue where normally there is little sign of it. Lymphadenoid tissue is a specialised kind of white fibrous tissue in the meshwork of which free cells collect. These cells produce blood corpuscles and also retain the fundamental digestive powers of unicellular organisms. In consequence of the situations in which lymphadenoid tissue is developed waste products of tissue change are prevented from entering the circulation until they have been rendered harmless, and thus its function of protecting the body from waste products—metabolites—of normal origin is capable of extension and is thus able to offer some resistance to the spread of disease, either by counteracting the poisonous substance resulting from diseased tissues or by actually destroying the germs of disease themselves. The pathological conditions to which lymphadenoid tissue is itself subject arise in the course of the performance of the protective functions. Being excited to over action lymphadenoid

[1] These lectures were illustrated by specimens from the Anatomical and Pathological Museums of the Royal College of Surgeons of England and of the Westminster Hospital.

Hosted by Google

tissue becomes the starting point of new growth, or it is replaced by scar tissue as a consequence of inflammation, so that the production of the red and white blood corpuscles is disturbed and the rest of the body thereby affected.

THE ORIGIN OF LYMPHADENOID TISSUE.

Lymphadenoid tissue is produced—(1) as lymphatic glands around the plexus of lymphatic trunks where they join in the axilla, groin, &c.; (2) around epithelial masses and glands, as the tonsils, thymus, salivary glands, and intestinal follicles; or (3) in the wall and sheath of the small blood-vessels in the spleen and bone marrow, favoured by the slow rate of the circulation. Fibrous connective tissue is changed into retiform tissue by a splitting up of its individual fibres, and into the meshwork so formed white cells emigrate from the capillary bloodvessels, and there, by multiplying, establish germinating centres. Fine capillaries permeate these germinating masses, but not so the lymphatics. The latter begin in a sinus outside the follicle, into which the young cells pass as they are pushed out from the centre by still newer formations.

Lymphadenoid tissue, like connective tissue generally, is prone to vary. An increase of the blood flow accelerates the multiplication of cells and so causes an overgrowth; a diminution in the blood-supply promotes a fatty metamorphosis, from which a renewal of lymphadenoid tissue may at any time take place—red marrow replaces the yellow, lumps of apparent fat develop again into glands, or minute glands consisting of only a single follicle can as the result of irritation become compound glands.

THE FUNCTIONS OF LYMPHADENOID TISSUE.

A.—The Formation and Destruction of Red Corpuscles.

The red corpuscle, although varying in type among vertebrates, is uniform in each species after embryonic life and during health. Its sole function is to carry oxygen, and in no other way can this action be carried out; the imperfect red corpuscles which gain access to the blood in disease appear incapable of properly doing this work. Further points of difference between it and the white corpuscle are that the red are never produced in excess, neither do they take part in new formations of any kind, nor have they any digestive powers, nor do they produce a protective secretion.

1. Red blood corpuscles are first formed from colourless cells outside the bloodvessels. They are first seen in the area vasculosa of the chick—i.e., outside the embryo itself, arising from cells of the mesoblast, previously colourless, which develop hæmoglobin in their protoplasm. There is therefore no *a priori* objection to the development at later periods also of young red cells or erythroblasts from colourless cells since the erythroblasts have in the beginning an origin in common with the young white corpuscles or leucoblasts (Neumann). On the other hand it is held that the erythroblasts of the embryo form a distinct order of cells which remain throughout life the only source of the red corpuscle (Bizzozero). The cells which form the blood islands begin to show hæmoglobin before the bloodvessel has developed around them, so that the first formation of red cells may be called extra-vascular. Later there is a very similar appearance in all the blood-forming organs, but it has not yet been settled whether the groups of erythroblasts undergoing division are placed in the lumen of the capillary or within a diverticulum of the capillary, whether they form the capillary wall itself at the point, or whether they are in the tissue outside separated from the blood stream by a layer of endothelium.

2. Red corpuscles after being formed in connective tissues are produced in later embryonic life in special organs. Erythroblasts are met with widely in the connective tissue and especially in the case of the mammalian embryo, in the walls of the umbilical vesicle, intestines, and bladder, as well as in the subcutaneous tissue (Saxer).[2] As the lymphadenoid tissues develop erythroblasts gradually disappear from the blood and only re-appear under abnormal circumstances. They also gradually disappear from the walls of the intestines and umbilical vesicle and their production becomes concentrated in the liver. The liver of the mammalian embryo takes a very important part in blood formation; it is relatively a very large organ, in the capillaries of which erythroblasts and leucoblasts are seen undergoing mitosis side by side, and according to Kostanecki[3] they have an origin in common. In late embryonic life this formation in the liver diminishes and ceases before birth. Erythroblasts are also seen during the latter part of embryonic life in the hilum and follicles of lymphatic glands, in the spleen, and in the thymus.

3. After birth the formation of red corpuscles becomes gradually confined to the red marrow in the higher mammals and man, although in lower vertebrates lymphadenoid tissue, especially the spleen, retains this function throughout life. The red marrow of birds forms a good material for demonstrating the various structures (Muir and Drummond).[4] In the capillary lumen are seen fully developed red corpuscles, in the wall are young red cells or erythroblasts which, although they project into the lumen, are fixed and show signs of mitosis; in the tissue around the capillary are the white cells rapidly dividing and passing towards the capillary channel.

On the whole it would appear most probable that the red corpuscles originate after birth from the small white cells of the marrow, and that the erythroblasts represent an intermediary stage. The alternative view is that the erythroblasts seen in the red marrow of the adult are a special class of cells directly derived from those found in the embryo.

Anæmia and regeneration of the red corpuscles.—There is an entire absence of clinical and experimental evidence as to the production of red corpuscles in excess. At any rate there is nothing comparable to leucocytosis and leucocythæmia in the case of the red corpuscle. A diminution in the rate of production of the red corpuscles seems to be the cause of the anæmia which occurs in women leading an indoor life, in those who have an insufficient supply of albuminous food, as well as in old age. And clinical experience definitely shows that the recovery up to the normal rate of production is a slow process. Anæmia can be produced experimentally in one of two ways, either by removing a considerable amount of blood or by the introduction into the circulation of some material which will increase the rate at which the red corpuscles are destroyed.

The regeneration of the blood after loss is seen when a considerable amount of blood has been taken from an animal by repeated venesections; the marrow then exhibits an increased mitosis both of colourless and coloured cells and becomes more red, the spleen swells up and erythroblasts showing mitosis are found within it, and similar immature nucleated red corpuscles are seen free in the blood stream (Freiberg[5] also Autokonenko[6]). According to Grünberg[7] erythroblasts are also to be seen in lymph glands, the intestinal follicles and tonsils, more especially when the spleen had been removed before the venesections were made. The lymph glands most affected were those of the mesentery, axilla, groin, and neck, which appeared to the naked eye enlarged and reddened. The lymphatics leading from the enlarged glands were filled with true red corpuscles, nucleated ones, and white cells. The germinating follicles of the lymph glands were exceedingly rich in leucoblasts undergoing mitosis. He speaks of the erythroblasts and red corpuscles as being in the lymphatic gland sinus, but only of leucoblasts within the stroma of the gland itself—under the foregoing condition no erythroblasts and red corpuscles were seen in the thymus (Braunschweig[8]). Venesection appears therefore to excite the leucoblasts to more rapid production, and there is a return to the embryonic state as regards the production of the red corpuscles. The alternative explanation of the appearances seen after great loss of blood is that the production of erythroblasts in the marrow is stimulated and that some are detached and carried to the spleen and lymph glands, where they continue to divide until the loss is restored, when the formation of red cells is again confined to the red marrow (Zenoni[9]; also Disse[10]).

Destruction of red cells in connexion with the spleen and also in the liver is attended by an increased production of leucocytes, and it is the increased production of these cells which appears to be the cause of the hæmolysis. According

to Hunter an increased destruction of red cells takes place during digestion in the spleen at a time when there is an increased production of leucocytes by that organ and by the gastro-intestinal wall. Hæmolysis in a greater degree can be brought about by acting either directly upon the blood or indirectly through the spleen and gastro-intestinal lymphadenoid tissue by injecting such a drug as toluylendiamin. The spleen enlarges several fold owing to engorgement with venous blood, iron containing pigments collect in the spleen and liver, and there is an increased secretion of bile, some of which may be absorbed and produce jaundice. Red corpuscles in various stages of degeneration are to be seen in the spleen. When, however, the spleen is first of all removed much larger doses of the drug are required to produce the hæmolysis which then takes place through the lymphadenoid tissue of the intestinal wall. The toluylendiamin at the same time markedly increases the number of white cells in the blood, and the explanation of its action is that it first excites leucocytosis, especially in the spleen, but also in the intestinal wall, and that it is the leucocytosis which is the cause of the hæmolysis. When drugs are injected which destroy the blood directly the removal of the spleen causes no alteration in the result (Hunter).[11] The anæmia, therefore, which is seen in the diseases of the lymphadenoid structures appears to originate in an excessive production of white cells, which hurry on and push out into the circulation whilst immature the red corpuscles in such a state that they cannot act fully as normal oxygen carriers and are liable to be destroyed.

B. *The White Blood Corpuscles.*

Leucocytes are all alike throughout the vertebrata, although in many species they can be divided into several kinds. They seem to be distinct from the fixed cells of the tissues, but this point is by no means definitely settled. White blood corpuscles, small marrow cells, the wandering cells, the lymphocytes as well as the free cells in the mouth, intestines, and bronchi, all originate from the cells in the meshes of lymphadenoid tissue. They are practically protozoa which can be kept alive outside the body and so be studied under the microscope. In the course of lymphadenoid disease the leucocytes, except for a temporary occasional diminution to a slight degree, are increased, sometimes, indeed, ten or twenty times, due to the abnormal excitation of lymphadenoid tissue.

1. In whatever situation these cells are found they exert a protective function due either to their secretion or to their ingesting and digesting powers. In the course of normal digestion an excess of leucocytes appears in the blood, and at the same time there is a marked enlargement of the spleen from which the cells are derived. This normal leucocytosis seems to have as its object the removal of some harmful products of digestion. In a less regular way some leucocytosis may occur during pregnancy and in the newborn infant.

2. Leucocytes play an active part in the removal of embryonic structures. Metchnikoff has described the removal by this means of the tadpole's tail, and Kowalewski that of the organs of the larva to make way for those of the imago. The epithelial structure of which the thymus is at first composed disappears before the invasion of the lymphadenoid tissue.

3 Free leucocytes in the mouth derived from the tonsils, in the intestine from the solitary and agminated follicles, and also similar cells in the bronchi, all have a deterrent action upon the growth of micro-organisms in these cavities.

4. As to inflammatory reaction, upon the inoculation of disease germs into an animal capable of offering a resistance to their attack, a local inflammatory reaction takes place, consisting of an increased circulation, but more especially of a rapid collection of leucocytes, and by multiplying rapidly these cells and their secretion may prevent the spread of the disease. If the organisms succeed in developing, the lymphadenoid tissues placed on the line of the lymphatics running from the site of inoculation may present a second line of defence against the invasion of the body. There is an increased circulation through the gland and rapid mitosis, so that more cells are produced, the gland appearing swollen and redder than usual. In it bacilli such as those of tubercle may lodge and be there digested. If, however, the bacilli gain the circulation they may be destroyed in one of two ways. They may be destroyed in the blood stream, an increased production of leucocytes being excited in all the lymphadenoid organs by the destruction of cells, or the organism may lodge in the spleen, as in anthrax and relapsing fever, and be there included by the splenic cells. If the animal, however, presents no great resistance, the micro-organisms quickly develop, whilst but few leucocytes gather round them. Even if they are checked for a time at the lymphatic glands, the organism succeeds in growing through and gains the circulation, which before death contains numbers free in the plasma, not included either in the white blood corpuscles or in the spleen cells.

The destruction of diseased germs may be due either to the cell ingesting them whilst still alive or by the secretions or products of the cell killing the organisms, and after they are dead the white cells swallow and digest them. It is generally agreed that white cells swallow and digest dead bacilli in the same way that unicellular organisms take in their food, a vesicle containing a peptic secretion is developed, the food material is dissolved, and the débris evacuated. But there has been much opposition to Metchnikoff's view that bacilli are ingested alive.

Wooldridge was the first to show that the secretions and cell products of lymphadenoid tissue can hinder or prevent the development of micro-organisms. In some experiments which I had the opportunity of watching he demonstrated that rabbits could be made immune to the inoculation of anthrax bacilli by injecting material derived from the thymus gland. Hankin and others have since then developed the large subject connected with the defensive proteids or alexins which are formed in connexion with the white cells. One method of experiment to show the power of the fluids in a resisting animal is to wrap the bacteria up so that no cells can come in contact with them, and in this way the most resisting anthrax spores may be destroyed. According to Kanthack and Hardy[12] the granules seen in some leucocytes, such as those which stain with eosin, represent the secretion of the cell.

Leucocytosis.—The production of leucocytes in excess of the normal can be brought about by the injection of the products of animal and of vegetable cells. Of animal products there are especially those derived from nuclei such as nucleo-albumin, nuclein, nucleic acid, uric acid, also other nitrogenous products such as urea, peptone, albumose, spermin, and bacterial products, pyocyanin, tuberculin; among vegetable materials are curara, papayotin, abrin, pilocarpin, terebinthin, and cinnamic acid. These either excite lymphadenoid tissue directly or do so indirectly by destroying cells. Many diseases cause a considerable leucocytosis probably in the same way; it is met with in cancerous cachexia, in the stage before death, after hæmorrhage, in inflammation of serous membranes, and in pneumonia. This leucocytosis when it occurs in the general diseases of lymphadenoid tissue is termed leucocythæmia or leukæmia. A slight degree of leucocytosis may exert a favourable influence. Löwy and Richter[13] found that rabbits required much larger doses of such virulent materials as culture of diphtheria, chicken cholera, pig typhoid organisms, or pneumococci, in order to affect them after a certain degree of leucocytosis had previously been produced whether by the injection of spermin, pilocarpin, &c., or by the production of hyperpyrexia by puncture of the corpus striatum. Pawlowsky[14] found rabbits in which a local leucocytosis was produced at the site of the inoculation of an anthrax culture by the injection of papayotin or abrin recovered, whereas the control animals similarly inoculated, but in which no leucocytosis was afterward produced, died. An excessive leucocytosis or leucocythæmia is unfavourable, not only by destroying red cells and disturbing the production as already pointed out, but by promoting an excessive destruction of white ones also. This continued cell destruction keeps up the excessive production by the lymphadenoid tissue and liberates from the nuclei of the cells proteids which set up intra-vascular coagulation, and hence the thromboses, ulcerations, and hæmorrhages which accompany leucocythæmia. It is the mature white corpuscles probably which have the chief protective power; the young white cells hurried into the blood in leucocythæmia

before they have developed cannot exercise the power, and they also tend quickly to break down.

We have thus traced back the anæmia and leucocytosis or leucocythæmia seen in connexion with the diseases of lymphadenoid tissue to the same cause—an excess of cell-products which excite the divisions of the leucoblasts, in consequence of which unripe red cells are hurried into the circulation from the bone-marrow, and, being inefficient as oxygen carriers, are soon included and destroyed in the spleen; at the same time the immature white cells which get into the circulation cannot fulfil their protective functions and may soon liberate substances which cause intravascular coagulation.

THE SPLEEN.

The spleen is an important blood-forming organ in amphibia and fish, and also in the mammalian embryo, but no proliferating red cells are to be seen in the healthy adult spleen of man. The centre of the Malpighian bodies is the site of the active germination of white cells, which pass to the periphery of the follicle and so get into the lymphatics, leaving the spleen; thence they pass through glands about the tail of the pancreas through the cœliac glands into the thoracic duct. The cells lining the spaces of the spleen pulp, through which the blood slowly flows, englobe and destroy red corpuscles and other foreign and harmful material. This function is especially active during digestion when the organ swells. The inherent rhythmical contractility residing in the unstriped muscle of the capsule and trabeculæ of the spleen favours the return of venous blood from the pulp spaces, especially after these have become distended during digestion. This rhythmical contractility has been not only the subject of experiment in animals, but has been observed during operations upon man. The spleen has been seen to contract under the eye when the return of venous blood had been hindered previously by its displacement. The spleen when prolapsed into a wound, so that the efferent veins are compressed, quickly becomes enormously swollen.

The effect of removal of the spleen.—Complete splenectomy produces a temporary anæmia and enlargement of lymph glands, but neither condition is well marked. They occur both after experimental splenectomy in animals and also in the human subject when a spleen has been removed which had up to a short time before been healthy—e.g., when the spleen has been removed for injury or on account of a twisted pedicle (Ballance).[15] No change follows upon the removal of a diseased spleen, either in the blood or in the lymph glands, for the functions of the spleen have already been assumed by the lymph glands, &c., before the operation. Some experimenters on animals have found them little affected by it. The existence of a spleniculus which hypertrophies when the spleen is removed may explain this absence of symptoms, or, owing to a small portion of the spleen being left on the proximal side of the ligature, the spleen may re-form (Laudenbach).[16] After partial resection, however, healing takes place simply by scar tissue without any hypertrophy.

The protective functions of the spleen.—The cells of the spleen pulp can stop and remove from the circulation abnormal blood corpuscles, pigment, and some forms of organisms. Large cells are seen enclosing red or white corpuscles, bacteria, &c. (cellules d'arrêt: Cæsaris Demel).[17] According to Metchnikoff[18] and Soudakewitch[19] the spirilla of relapsing fever multiply rapidly in the blood, but on reaching the spleen they are taken up and destroyed. If the cells become exhausted spirilla escape, and becoming again free in the blood rapidly increase again. Werigo[20] noted that anthrax bacilli injected into the ear vein of a rabbit reach the spleen and liver and are there included by cells. But soon free bacteria are found in the spaces of the spleen pulp, and then they multiply rapidly and cause the spleen to swell. During the last stages of the disease the bacteria escape into the general blood stream. There are other parasitic diseases—such as typhoid fever, diphtheria, and malaria—where the spleen appears also to play, in part at least, a protecting *rôle*. But, on the other hand, there are conditions in which it remains unaffected.

The pathological changes in the spleen arise either in connexion with disturbances of its circulation or are due to inflammatory changes consequent upon the collection of morbid products in it. A diseased spleen affects the body generally either by producing leucocythæmia and anæmia or by acting as an abdominal tumour.

Circulatory disturbance.—Venous obstruction concurrent with obstruction to the portal circulation causes first an engorgement of the pulp, then a general increase of connective tissue which does not especially pick out the follicles. Embolism affects the spleen according to the vessel, whether a main vessel is affected or several small ones. In pyæmia the necrosis goes on to suppuration around the bacteria which have lodged there. Infarcts from thrombosis are a special feature of the spleen. They are met with in typhoid fever, malaria, and leucocythæmia owing to the coagulation produced by the breaking down of leucocytes. A wedge-shaped mass is formed abutting on the surface, which can thus be distinguished from other changes.

Inflammatory changes the result of infection.—The spleen is rarely affected by tubercle until the disease has become generalised. The bacilli have to pass through lymphatics and lymphatic glands into the blood stream before they can reach the spleen. The tubercles generally form in the sheath of the bloodvessels and in the Malpighian bodies. The Malpighian bodies appear as pale, firm masses which may easily be confounded with the changes due to lymphadenoma. Syphilis, especially when inherited, affects the spleen either directly in the form of gummata or by a general overgrowth of connective tissue or indirectly by starting amyloid disease. Amyloid disease may commence in a previously healthy spleen from some cause other than disease of lymphadenoid tissue, and by commencing in the follicles form the so-called "sago spleen," or it may be widely diffused around the vessels of the pulp, and give rise to a hyalin appearance on section which has been compared to bacon rind. Amyloid disease may also affect a spleen previously altered by malaria, tubercle, syphilis, &c.

The spleen in malaria.—In malaria the spleen is primarily affected by an increased vascularity, in connexion with which there is an inclusion by the cells of the pulp of the corpuscles which are degenerating owing to the parasites, and there is left behind much pigment. This increased vascularity may cause only a temporary swelling of the spleen, and the organ afterwards subsides. The more permanent enlargement is due to an increased connective tissue formation whether specially of the follicles or diffusely of the pulp. Infarcts also occur. The stopping function of the spleen may be so far successful that the patient ceases to suffer from malaria. Presumably in such a case the spleen has taken a prominent part in removing the parasites from the circulation. The spleen may not, however, subside after the cessation of the malaria, but remains an abdominal tumour, obstructing by its large size the abdominal circulation, and being in danger of causing at any time intra-peritoneal hæmorrhage either by the rupture of the tumour itself from some slight injury or often adhesions which have formed between the capsule and neighbouring structures. Such patients remain thin and anæmic, and an improvement in health may follow on splenectomy, always provided that the malaria has subsided and there is no leucocythæmia present. The improvement may be due simply to the removal of an abdominal tumour forming a mass of diseased tissue.

THE BONE MARROW.

Red and yellow marrow.—From the time when ossification commences in the previously non-vascular fœtal cartilage by an invasion of bloodvessels from the perichondrium there appear erythroblasts developing into red corpuscles, and at a later period leucoblasts, which form the small colourless cells. Wherever ossification is going on there is an active formation of red corpuscles; and not only in cartilage and membrane, but also in exceptional cases of ossification, such as those which occur late in life in the laryngeal and rib cartilages, Neumann found erythroblasts. The formation of the red corpuscles in the red marrow is a feature common to all vertebrates, and is only absent in those fish whose cartilage persists throughout life as solid rods. In adult mammals it is the sole manufactory for the red corpuscles. The red marrow, however, gradually disappears from the bones of the extremities, being last of all found in the cancellous tissue of the upper

end of the humerus and femur. It is present in the flat bones, especially in those of the vertebræ and skull, although even in the flat bones yellow marrow takes the place of much of the red late in life. The yellow marrow which fills the long bones of the adult must not be regarded as identical with the fat of connective tissue. It must be compared with the fatty masses which replace the thymus and lymphatic glands, for under certain circumstances the yellow again changes to red. It is also asserted that the administration of yellow marrow has had a beneficial effect in anæmia by promoting the production of red corpuscles, a result which cannot be attributed to simple fat. Marquis[21] has described the marrow in the long bones of the frog, which is red during the active period in spring, becomes mixed with yellow during the summer, but during the autumn and winter rest is entirely yellow. Yellow marrow may, therefore, be regarded as red marrow in a state of quiescence. In chronic wasting diseases such as pulmonary emphysema, tuberculosis, chronic renal nephritis, and also on account of starvation nearly all the fat may be absorbed, causing the yellow marrow to have a jelly-like appearance. The fatty marrow may, on the other hand, increase accompanying eccentric atrophy of the bone until the bone becomes a mere shell and it may even float in water. This occurs especially in cases of senile osteomalacia.

The myeloplaxes or giant cells of the marrow.—The multinucleated myeloplaxes are found in Howship's crypts bordering on the marrow. They show marked powers of movement on the warm stage and also englobe particles. If carmine be injected into the marrow cavity, it is found included in the giant cells near the site of the injection. If an excess of the carmine be injected, the giant cells containing these particles are easily seen in the blood, and carmine is also found in the lungs, liver, spleen, and kidneys, showing that there is an easy exit from bone (Arnold).[22] Multinuclear giant cells are carried into the blood and appear there under a number of circumstances. But their presence in the blood does not indicate any excessive production of them in the marrow.

Lymphoid marrow.—The yellow marrow may be replaced by marrow varying in colour from a pinkish grey up to a deep red. But the lymphoid marrow as met with in disease is by no means the same as the red marrow of the young healthy animal. There is in lymphoid marrow not only a marked increase of the small colourless marrow cells and of the nucleated red cells, but many of the latter are found free in the capillaries, and there is an increase of blood pigment without there being evidence that this pigment can be worked up again as hæmoglobin. The excess of pigment is the result of hæmorrhages due to thrombosis of the blood-vessels, and this thrombosis is a sign that a destruction of leucocytes is in progress. Lymphoid marrow is best marked in pernicious anæmia, in which disease the prevailing factor is the excessive destruction of blood in the spleen and liver. In a like manner chronic septic absorption, especially chronic suppuration of bone, tends to produce lymphoid marrow. In cancerous cachexia a similar condition of the marrow may be also found, but it is necessary to distinguish lymphoid marrow from a diffuse infiltration of the marrow by secondary cancerous growths, which is often difficult. It is difficult to draw a sharp distinction between the lymphoid marrow produced by lymphadenoma accompanied by leucocythæmia and anæmia and new growths of lymphadenoid structure originating in the marrow from the small marrow cells (myeloma or lympho-sarcoma), except that these growths are circumscribed, at any rate in the earlier stages.

The inflammatory diseases of the marrow, as compared with those of the spleen and lymphatic glands, are limited in variety, for the organisms of most infectious diseases are not arrested in the bone. Only a few kinds are so stopped—e.g., tubercle bacilli, the organisms of syphilis, and pyogenic cocci. They infect especially the ends of the long bones of young subjects in which red marrow is still present, and which are especially vascular in the neighbourhood of the epiphyses. These organisms arriving by the circulation settle down and grow, being especially favoured if a blood-clot due to some slight injury be present. In older patients the periosteum, as the most vascular part of bone in the adult, is more likely to be affected than the marrow.

The Arris and Gale Lectures

ON

SOME POINTS IN THE PATHOLOGY OF HEART DISEASE.

Delivered at the Royal College of Surgeons of England on Feb. 22nd, 24th, and 26th, 1897,

BY ERNEST H. STARLING, M.D., M.R.C.P. LOND.,
JOINT LECTURER ON PHYSIOLOGY AT GUY'S HOSPITAL.

LECTURE II.[1]

Delivered on Feb. 24th.

THE EFFECTS OF HEART FAILURE ON THE CIRCULATION.

MR. PRESIDENT AND GENTLEMEN,—In my previous lecture I discussed the conditions which may lead to a failure of the compensatory mechanisms of the heart. In this lecture I propose to deal with the effects of such failure on the circulation generally, that is to say, on the blood, and the pressure and velocity of this fluid in the different parts of the circulatory system.

I would, in the first place, remind you of some of the elementary facts in the physiology of the circulation. It must be remembered that the vascular system forms a closed circuit of elastic tubes. In one part of this circuit is included a pump—the heart, the contractions of which will, in consequence of the presence of valves, propel the contained fluid in one direction only. In this system there is a resistance to the flow of blood in consequence of the friction between the blood and the vessel wall in the small arteries and to a lesser extent in the capillaries. There is also a difference in the structure of the walls of the tube on the arterial and venous sides, so that a small rise of pressure in the veins will cause a considerable dilatation and increase in capacity of these vessels, whereas on the arterial side the injection of a small quantity of fluid will bring about a large rise of pressure. If the blood is at rest in the system, and assuming that all parts of the system lie in one plane, it is evident that the pressure in all parts of the system must be the same. This pressure was termed by Weber the mean systemic pressure (not to be confused with mean arterial pressure), and amounts in a large dog to about 10 mm. Hg. If the heart now commences to beat, fluid is pumped from the venous side into the arterial side, where it accumulates to a certain extent in consequence of the resistance in the smaller arteries and capillaries, so raising the pressure on the arterial side and lowering the pressure on the venous side. The fall, however, on the venous side is not directly proportional to the rise on the arterial side, since, as I have pointed out above, a large change in the capacity of the veins is only attended by a small variation of the pressure within them, whereas the blood removed from the veins cannot be pumped into the much less distensible arteries without causing in them a considerable rise of pressure. Somewhere in the circulation there must be a point where the pressure is neither raised nor lowered and where, therefore, the pressure is independent of the cardiac activity. At first sight it might be thought that this neutral point must lie in the situation of the peripheral resistance—viz., between the arterioles and capillaries. It must be remembered, however, that even when the blood is circulating there is not necessarily, although there may happen to be generally, a fall of pressure all the way round the system. What does fall from the heart through the arteries, capillaries, and veins back to the heart is the energy in the fluid at any given point. The total energy of a mass of blood at any point in the system is represented, not only by the hydrostatic pressure at that point, but also by the kinetic energy of the moving mass of fluid ($= \frac{1}{2} mv^2$). In the capillaries, in consequence of the great area of the bed, the velocity is very small and rapidly increases in the veins. Hence the proportion of the total energy represented by $\frac{1}{2} mv^2$ is relatively small in the capillaries and relatively large in the veins. The other

[1] Lecture I. appeared in THE LANCET of Feb. 27th, 1897.

Hosted by Google

factor—the pressure—must be therefore relatively large in the capillaries and small in the veins. It thus follows that the neutral point in the vascular system, where the mean systemic pressure is neither raised nor lowered by the inauguration of the circulation, lies considerably on the venous side of the capillaries—at any rate, in most parts of the body.

Now in such a system it is evident that a failure of the heart pump, however induced, whether by vagus-inhibition, by damaged valves, aortic stenosis, or cardiac fatigue, can only cause a return of the pressures in the various parts of the system to one level—the mean systemic pressure. We shall, therefore, have a rise of pressure on the venous side of the neutral point and a fall of pressure on the arterial side. By actual experiment we may ascertain the extent and direction of the change of pressure in the various parts of the circulation. To this end we may register the pressure in the arterial system, in the vena cava, and in the portal vein. We may deal in the first place with the case in which the vessels are removed from the interference of the vaso-motor centre by section of the cord or splanchnic nerves, so that we may study the pure effects of cessation of the circulation. In such an experiment the pressures before cardiac inhibition were: Femoral artery, 58 mm. Hg; portal vein, 73 mm. H_2O; and femoral vein, 62 mm. H_2O. On exciting the peripheral end of the right vagus the heart stopped, and ten seconds later the pressures were: Femoral artery, 20 mm. Hg; portal vein, 72 mm. H_2O; and femoral vein, 68 mm. H_2O. After three minutes the pressures were: Femoral artery, 6½ mm. Hg = 84 mm. H_2O; portal vein, 83 mm. H_2O; and femoral vein, 82 mm. H_2O; so that complete equilibrium was established between the pressures at all parts of the system. Here the total failure of the heart pump caused a considerable fall in arterial pressure, a considerable rise in the vena cava pressure, and practically no alteration in the portal vein. The last represents, therefore, a neutral point of the system; in all parts distal to the portal vein there must have been a fall of pressure. The only part of the body, therefore, where heart failure can by itself cause a rise of pressure is in the large veins of the trunk and possibly in the capillaries of the liver.

In the living body, however, we never get a reproduction of so uncomplicated conditions. In a closed circuit of tubes, as described by Weber, the mean systemic pressure can only be increased by injecting a further amount of fluid into the system or by diminishing the capacity of the system. In the body neither the amount of circulating fluid nor the calibre and capacity of the vessels forming the system are constant quantities, and it is possible that changes in the heart leading to its failure may have as an immediate consequence an alteration either of the capacity of the system or of the amount of circulating fluid. We might therefore have, as the remote effect of heart-failure, an increase in the pressures, not only near the heart, but also in the peripheral capillaries. Thus, if we repeat the experiment of vagus inhibition just described, but carry it out on a normal animal, we find that at first the results of stoppage of the heart are exactly similar to those already described. After the inhibition has lasted from twenty to forty seconds the anæmia of the brain causes a strong excitation of the vaso-motor centre. We therefore get extreme vascular constriction, with diminution in the capacity of the system, as is evidenced by a considerable rise in portal, vena cava, and arterial pressures. We may, in fact, in consequence of this constriction, obtain a doubling of the mean systemic pressure. Another point which we must bear in mind is that the quantity of circulating fluid is intimately dependent on the pressures at various parts of the vascular system. Almost every fall of arterial pressure gives rise to a diminished concentration of the blood due to the taking up of fluid by the blood-vessels from the tissues, whereas a rise of blood pressure augments the concentration by causing increased transudation. With these varying factors to take into account it is impossible to predict in our study chairs what will be the effect of failure of the heart pump on the pressure and distribution of the blood throughout the different parts of the body, but we must in each case have recourse to experiment.

In attempting to deal with this subject experimentally one is met at the outset by the difficulty of reproducing clinical phenomena in the laboratory. We have to choose a method of interfering with the action of the heart-pump which resembles in some degree the chronic processes of nature; artificial stenosis or valvular lesions are useless for this purpose, owing to the wonderful powers of compensation possessed by the normal heart, so that the margin between complete compensation and absolute failure becomes too narrow for experiment. The best method is perhaps that adopted by Cohnheim—viz., the interference with the action of the heart by the injection of oil into the pericardium. By this means we may effect an impairment of the heart's action of considerable duration without running the risk of stopping its action altogether. In the experiments of this nature carried out by Cohnheim, this observer measured the pressures in the carotid artery and in the jugular vein, and noticed that as the diastolic expansion of the ventricle began to be affected by the injection of oil into the pericardium there was a fall of arterial, accompanied by a rise of venous, pressure. The jugular vein is, however, so near the heart and so influenced by the diastolic suction of this organ that one cannot deduce a general rise of venous pressures from the occurrence of a rise in this vessel. I have, therefore, repeated Cohnheim's experiment with two modifications. In the first case I have measured simultaneously the pressures in the inferior vena cava, in the portal vein, and arterial system, while at the same time oil was being injected into the pericardium. In the second series of experiments I have observed the influence of the pericardial injection on the circulation in the limbs, using as my guide the volume of the limbs.

We will consider, in the first place, the effects of injecting oil into the pericardium on the pressures in the portal vein, vena cava, and in the arterial system. In these experiments the animal having been anæsthetised with a large dose of morphia and A.C.E. mixture, cannulæ were placed in the central end of the splenic vein, all other vessels of the spleen having been ligatured, in the central end of the iliac vein, and in the central end of the carotid or femoral artery. The venous cannulæ were connected with manometers filled with coloured $MgSO_4$ solution, so that the height of the fluid could be easily read off on the graduated scales behind the tubes. The arterial cannula was connected with an ordinary mercurial manometer, the excursions of the meniscus being registered on the blackened surface of a kymograph. At the end of the experiment, the abscissæ having been taken, the readings were plotted out as curves. After the attachment of the manometers the chest was opened in the middle line and a cannula tied into an opening in the pericardium for the injection of oil, which was allowed to run in from a graduated burette. In one experiment of this sort the pressures at the beginning of the experiment were: arterial, 90 mm. Hg; portal vein, 128 mm. $MgSO_4$; and vena cava, 36 mm. $MgSO_4$. 20 c.c. of oil were then allowed to flow into the pericardium. This had no influence on the pressures in any of the vessels. Injection of another 20 c.c. then caused a slight rise in the vena cava to 40 mm. $MgSO_4$, but no distinct change in the other vessels. Injection of another 20 c.c. caused a rise—the vena cava to 58 mm. $MgSO_4$, a slight but temporary fall in the arteries, and no change in the portal vein. Another 10 c.c. injected gave a large rise to 76 mm. in the vena cava, a slight rise to 134 in the portal vein, and practically no effect on the arterial pressure. I had now arrived, after the injection of 70 c.c. of oil, at the limits of compensation possessed by the heart and vascular system for the hindered diastolic expansion. Injection of another 20 c c. of oil now caused a very marked change in all the pressures. The arterial pressure sank to 56 mm. Hg, while the portal pressure rose to 160 mm., $MgSO_4$, and the vena cava pressure to 124 mm. $MgSO_4$. The injection of a further 10 c.c. put a stop to the circulation altogether. The arterial pressure sank to 26 mm., and then as the heart stopped to 18 mm., while the portal vein and vena cava rose first to 180 and 170 mm., and then with the stoppage of the heart, to 215 mm., the pressures in both vessels being practically the same. The oil was now suddenly let out of the pericardium, and the heart, after a short pause, re-commenced beating. The first effects of the re-establishment of the circulation were striking. With the very first heart-beat the pressure in the vena cava sank with extreme rapidity to its normal pressure of 36 mm., and then rose slightly to about 40 mm. $MgSO_4$. The arterial pressure rose with equal rapidity to a point far above its previous height—viz., 146 mm. Hg., to fall rapidly to 84 and then rise gradually towards the end of the experiment. The pressure in the portal vein, instead of falling, like that in the vena cava, continued to rise rapidly

Hosted by Google

on the re-commencement of the heart-beats until it attained the enormous height of 322 mm. $MgSO_4$, whence it fell in the course of the next six minutes to 148 mm. $MgSO_4$—i.e., somewhat above its height at the beginning of the experiment.

How are we to explain these results? It is evident that we have here at least two factors at work—viz., first, the gradual impairment and ultimate failure of the heart pump; and, secondly, a diminution of the capacity of the vascular system and consequent rise of the mean systemic pressure, brought about by the activity of the vaso-motor centre. We have already seen that the effect of a pure stoppage of the heart is to cause a rise of pressure in the vena cava and a fall in the arteries, while the pressure in the portal vein, which represents the neutral point of the system, remains practically unchanged. In this case, however, the vena cava pressure not only rises to the height of the normal portal pressure, but attains nearly double this amount, this rise being accompanied by a parallel rise in the portal vein and a large fall in the arteries. Now we know that any anæmia of the vaso-motor centre, however caused, excites its activity, and therefore active constriction of the vessels all over the body, but especially in the splanchnic area. As soon, therefore, as the hindrance to the diastolic expansion becomes sufficient to diminish the normal outflow of blood from the heart in a given time there is a fall of arterial pressure, and the vaso-motor centre is excited and endeavours to restore the arterial pressure to its normal height by an active constriction of all the arteries. That at the moment in the experiment when the heart stops the bloodvessels are constricted is shown by the enormous rise in pressure which occurs directly the heart re-commences to beat. The heart, which is richly supplied with blood from the distended venæ cavæ, propels this into the arteries, fills them up, and then has to overcome the resistance of the constricted arterioles, so that the pressure rises high above its normal amount, to sink again as this raised pressure furnishes a sufficient supply of blood to the vaso-motor centres of the brain, which, it seems, from the work of Bayliss and Hill and other observers, do not participate in any general vascular contraction. The rise of pressure in the portal vein is analogous to that which occurs in the arteries, and is due to the constriction of the branches of the portal vein in the liver, so that the trunk of this vessel is supplied with blood more rapidly than can be passed through the liver into the vena cava. This experiment brings out two facts which are of importance for our knowledge of the conditions in heart disease. In the first place, any heart failure will tend to be accompanied by active vascular constriction and a rise of mean systemic pressure, so that the pressure at the neutral point of the system, as well as on the venous side of this point, must be raised considerably above normal. In all cases, therefore, of heart failure there will be a large rise of pressure in the capillaries of the liver. In the second place, the existence of this vascular constriction shows that the heart, although inadequate to perform its functions, cannot relieve itself by calling on the depressor mechanisms when by so doing it would diminish below what is necessary the blood-supply to the vaso-motor centre.

We have now the important question to decide as to how far back this rise of venous pressure goes. Is the diminution in the capacity of the vascular system consequent on the vaso-constriction ever so great as to raise the pressure in the small veins and capillaries in the peripheral parts of the body such as the limbs? To determine this question one must carry out an experiment similar to the above, but at the same time enclose one limb in a plethysmograph and record changes in its volume by means of a Marey's tambour or a piston-recorder connected with the plethysmograph. If an experiment be arranged in this way and oil injected into the pericardium, it is found that, while the arterial pressure remains constant, practically no change occurs in the volume of the limb, although there may be a rise of pressure both in the portal vein and vena cava. As soon, however, as the compensatory mechanisms become inadequate and the arterial pressure begins to sink, the volume of the limb also diminishes. Thus the volume of the limb, and presumably therefore the pressure in its smaller vessels, including its capillaries and veins, is directly proportional to the arterial pressure, and is not altered by considerable changes in the venous pressures consequent on heart failure. We may conclude, therefore, that, even with coincident vascular constriction, the effect of heart failure must be a fall and not a rise of blood pressure in the capillaries and smaller veins of the limbs. Since this conclusion is opposed to the ordinarily accepted view, which we owe largely to Cohnheim, that failure of compensation in heart disease leads to a general rise of venous and capillary pressures in all parts of the body, we must inquire whether there may not be other factors at work by which a rise of pressure might be produced. Especially we can elevate the mean systemic pressure, not only by vascular constriction, but also by increasing the amount of fluid contained in the system—i.e., by causing a plethora. Are there any conditions in heart failure which might lead to a plethora sufficient to raise the venous and capillary pressures in the limbs in the absence of any arterial rise?

I pointed out last year that a slight degree of plethora must be the invariable consequence of any heart failure, since a fall of capillary pressure increased the fluid taken up from the tissues and diminished the transudation into the tissues. We therefore get a fall of specific gravity of the blood whenever the arterial pressure is lowered by heart failure or by bleeding. It will be noticed, however, that such an increased absorption of fluid from the tissues must come to an end as soon as the cause of the absorption is removed—i.e., as soon as the capillary pressure is restored to its normal amount, so that a plethora brought about in this way could never be made responsible for a rise of capillary pressure in the limbs. Of course, even when the pressure in the limb capillaries has attained its ordinary amount there is one factor left tending to produce a hydræmia or hydræmic plethora—viz., the diminished urinary flow in consequence of lowered arterial pressure,—and last year I thought that possibly this factor would be sufficient to cause a condition of hydræmic plethora in heart disease and raised capillary pressure in the limbs. Whether this is or is not the case can only be decided by direct clinical observation. If a condition of hydræmic plethora be present in uncompensated heart lesions we should expect to find—(1) a diminution in specific gravity of the whole blood; and (2) a diminution in the amount of hæmoglobin and number of corpuscles present in the blood.

With regard to the first point, it has been shown fairly conclusively by Lloyd-Jones that in failure of compensation there is a marked diminution in the specific gravity of the whole blood. Now this diminution might be due to a hyperplasmia of the blood, possibly brought about by a condition of plethora or to a decrease in the solids of the plasma or corpuscles or of both—i.e., either to hydræmic plethora or to hydræmia. In order to decide which of these two conditions is responsible for the lowered specific gravity we must have recourse to the determination of the hæmoglobin and corpuscles in the blood of such persons. On referring to the various researches on the subject we find a considerable discrepancy. According to the majority of writers, the relative number of corpuscles in the blood of patients suffering from heart disease is increased, whereas according to others, such as Stintzing and Gumprecht, the exact opposite is the case. In face of this discrepancy Dr. Fawcett has undertaken a series of observations on the amount of hæmoglobin and the number of corpuscles in the blood of patients suffering from heart disease, whether accompanied or not by signs of so-called "backward pressure." Although these researches are not completed, he has kindly allowed me to quote some of his results in this lecture.

The first case investigated seemed at first to favour the hypothesis of the existence of hydræmic plethora.

CASE 1. *Mitral disease.*—This patient, aged thirty-three years, was admitted to hospital on Oct. 30th, 1896, with œdema and ascites of a month's duration. On Nov. 3rd the hæmoglobin amounted to 48 per cent.; on Nov. 14th it was 50 per cent.; on Nov. 24th, 54 per cent.; on Nov. 30th, 65 per cent.; and on Jan. 10th, 1897, 85 per cent. Here there was a marked increase in the percentage amount of hæmoglobin during the patient's stay in the hospital. It must be remarked, however, that the œdema and ascites had disappeared entirely by Nov. 11th, when the hæmoglobin was only 50 per cent., and that the condition of the blood only commenced to improve markedly with the administration of iron, which began on Dec. 7th. In all the other cases investigated the amount of hæmoglobin, even when marked ascites was present, was either above normal or very little below.

CASE 2. *Mitral stenosis and regurgitation, with tricuspid*

Hosted by Google

regurgitation.—This was a patient aged twenty-eight years. On Nov. 11th the hæmoglobin amounted to 100 per cent. and there were œdema of the legs and ascites. On Dec. 12th the hæmoglobin was 97 per cent., and the ascites and œdema had disappeared.

CASE 3. *Mitral stenosis (ulcerative endocarditis).*—This was a patient aged forty-one years. On Nov. 11th the hæmoglobin was 105 per cent., and there was much œdema. On Nov. 24th the hæmoglobin had risen to 110 per cent.; there was still much œdema, and the patient died on Nov. 27th.

CASE 4. *Bronchitis with heart failure.*—This was a patient aged twenty-three years. On Nov. 18th the hæmoglobin amounted to 97 per cent., and there were œdema and ascites. On Dec. 7th the hæmoglobin was 90 per cent., and the patient was in the same condition and died on Dec. 8th.

In nearly all cases it was found that the number of corpuscles was increased to a greater extent than the hæmoglobin, so that the corpuscles themselves contained less hæmoglobin than normal.

It will be seen that these results lend no support to the view that failure of compensation is attended by a condition of plethora. They tend rather to show that the amount of blood in the circulation is subnormal, unless we adopt the unlikely supposition that the defective aeration of the blood in this disease acts like mountain air, in stimulating the production of red corpuscles and hæmoglobin. We must, therefore, conclude that there is no condition of the plethora, hydræmic or otherwise, in heart disease, and that the lowering of the specific gravity of the whole blood is due to a diminution of solids of the plasma, and possibly also of the corpuscles—i.e., there is hydræmia, but no plethora. Since the volume of the fluid contained within the vascular system is not increased, the only factor which can contribute to the raising of the mean systemic pressure, and a consequent production of a rise of pressure in the peripheral veins and capillaries by failure of the heart-pump, is the active vascular constriction caused by the anæmia of the vaso-motor centre. We have already studied the limits of a rise of systemic pressure so produced, and have seen that it is inadequate to bring about a rise of capillary pressure in the limbs when the heart fails. We must, therefore, conclude that the ordinarily accepted notion is erroneous which assumes that the pressure in the capillaries and veins all over the body in uncompensated heart disease is raised. The pressure must in these situations follow the arterial pressure, and thus be lowered. The only parts of the body where there can be a rise of pressure in heart disease are the capillaries of the liver (whence the well-known "nutmeg" liver of this disorder) the great veins near the heart, and possibly in the system of capillaries which surround the tubules of the kidney. In the limbs, and probably in the abdominal viscera other than those just mentioned, the capillary pressure will be lower than in the normal individual.

For many years, and, indeed, since the time of Richard Lower, we have been wont to pride ourselves on our exact understanding of the factors responsible for the production of anasarca and ascites in heart disease, and have confidently ascribed the increased serous exudation to the rise of pressure in the capillaries due to the transmitted backward pressure from the incompetent heart, and the dropsy of heart disease is generally regarded as affording striking support to Ludwig's filtration hypothesis of lymph formation. The whole argument is, however, based on the false assumption that there is a rise of pressure in the smaller veins and capillaries in heart disease; whereas, as I have just shown, the reverse is the case. We must, therefore, seek for some other explanation of the dropsy in this disease.

VICTORIA HOSPITAL, SWINDON.—The ninth annual meeting of the Victoria Hospital, Swindon, was held on Feb. 13th. The report of the general committee showed the total expenditure for the past year to have been £419, against receipts amounting to £500; the sum of £107 was due to the treasurer on account of the building and furnishing fund. There were 153 patients admitted in 1896, against 131 in 1895, the average cost of each being 2*s.* 11½*d.* daily. The committee suggested that the celebration to be held in Swindon on account of the Queen's long reign should take the form of raising funds for the benefit of the hospital.

A SUCCESSFUL CASE OF INTRAVENOUS INJECTION OF SALT SOLUTION AFTER LAPAROTOMY IN A CASE OF RUPTURED TUBAL GESTATION.

BY ARTHUR H. N. LEWERS, M.D. LOND.,
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

ON April 20th, 1896, I was called in by Dr. Fennell of Dalston to see a married woman, aged thirty years, when the following history was obtained. She had been married nine years and had had four children, the last nineteen months previously. There had been no miscarriages. Instruments were used at the first confinement, but not at the others. She generally got up ten days after her confinements, but after the last confinement she was in bed nearly two months on account of what the medical attendant told her was peritonitis. Menstruation was quite regular up to Feb. 26th, 1896, but she "saw nothing" in March. She took some pills on April 4th with a view to bringing on the period; these gave her great pain. On April 6th a vaginal discharge containing blood began, and she had been losing blood more or less ever since up to the day when I first saw her (April 20th). The patient said that a solid substance came away from the vagina on April 11th when passing urine. She had had some pain in passing urine and had suffered from constipation since April 6th. She said that she had had pain at the lower part of the abdomen, especially over the left iliac region, for some days before I saw her, and there was an especially sharp attack of pain on the early morning of April 20th. On examination of the abdomen there was some resistance in the left iliac region and some tenderness there. The breasts did not appear active. On vaginal examination there was a little blood to be seen about the external parts. The uterus was anteverted and slightly flexed and distinctly larger than normal, although the sound only passed three inches. A swelling was felt behind and to the left of the uterus occupying the left posterior quarter of the pelvis. It was distinctly elastic and could be displaced a little by upward pressure. The case appeared to me in all probability to be one of extra-uterine pregnancy. The question arose as to whether the substance passed by the patient a few days before I saw her might not have been an ovum, and the case one of ordinary miscarriage, with possibly some peri-uterine inflammation; but, on the whole, it seemed to me much more probable that the case was really one of tubal pregnancy, and that the substance in question said to have been passed, if anything more than a clot, was probably a decidual cast of the uterus. The arrangements of the patient's home were not very convenient for performing abdominal section, and accordingly I had her removed to the London Hospital, where she was admitted under my care on April 21st.

Operation.—On April 23rd she was anæsthetised with the A.C.E. mixture; the abdomen was opened in the usual way and was found to contain blood and masses of clot. The left Fallopian tube was considerably enlarged and had ruptured. The left ovary contained a large corpus luteum with a well-marked yellow convoluted border. The uterine appendages on the right side were also slightly enlarged, and the uterus was considerably enlarged. The appendages on both sides were removed in the usual way and the peritoneum well washed out with saline fluid. A Keith's tube was inserted and the rest of the abdominal incision was closed. When this had been done it was observed before the dressing was put on that the Keith's tube had become full of dark blood. This was withdrawn once or twice, but the tube very soon became again full of blood. The abdomen was therefore re-opened to discover the source of the bleeding; the stumps of the broad ligaments were pulled up and inspected, but no blood was coming from them. On looking at the back of the uterus there were some quite superficial tears in the peritoneal coat near the level of the internal os, from which blood was coming rather freely. Several attempts were made to control this bleeding by passing silk ligatures on a curved needle under the tissues at the bleeding point and tying, and also by applying Wells's forceps; but the tissues were so friable that the more manipulation took place in the neighbourhood of the tears

Hosted by Google

the worse the bleeding became. I therefore decided to perform supra-vaginal hysterectomy; the uterine arteries were ligatured on each side outside the uterus, and then the body of the uterus was cut away. A large pair of Wells's forceps was left on, but the surface of the stump oozed rather freely, and two silk ligatures were passed right and left from before backwards and tied firmly to check it. Some iodoform gauze was packed over the stump, a small piece being left sticking out at the lower end of the wound. A Keith's tube was inserted and the remainder of the wound closed in the usual way. The re-opening of the wound and the various measures that were required to permanently control the bleeding had occupied a considerable time, and, besides, a good deal of blood had been lost, taking into consideration what was extravasated in the abdomen by the extra-uterine sac before operation, and also reckoning the amount that was lost from the superficial tears on the back of the uterus. How these were produced I am unable to say positively. My impression is, however, that some of the masses of clot removed were partially adherent to the uterus, and that in removing them the peritoneal coat of the uterus must have been slightly torn, and then the tissues were so friable that almost any kind of manipulation—sponging, pulling up the uterus, and the like—seemed to increase the laceration and the hæmorrhage. At all events, at the end of the operation, when the patient was put back to bed, her face was quite white, her hands and feet quite cold, and no pulse could be felt at the wrist; and I have no doubt whatever that had she been left without further treatment she would certainly have died, probably without regaining consciousness at all. I decided, however, to try the effect of injecting salt solution into the veins. Our stock of boiled water had been exhausted in washing out the abdomen during the operation, so that the water used in making the salt solution for intravenous injection was merely the water out of the kettle and out of the tap. The salt solution, however, was sterilised, because we keep a concentrated solution of it which is carefully prepared and boiled before each operation. A glass reservoir was filled with salt solution at the temperature of 100°F. and containing a drachm of common salt to each pint. The injection was made into the median cephalic vein of the left arm, the necessary pressure being obtained simply by hanging up the glass reservoir on the wall about three feet above the patient's head. After one pint had been injected the patient's pulse at the wrist could be felt. After four pints had been injected the pulse was as good as it had been before the operation. The patient made a good recovery. I have seen her several times since she left the hospital; the abdominal wound is soundly healed, and she remains quite well.

Harley-street, W.

ON THE APPLICATION OF THE SERUM TEST TO THE DIFFERENTIAL DIAGNOSIS OF TYPHOID AND MALTA FEVER,

AND ON THE FURTHER APPLICATION OF THE METHOD OF SERUM DIAGNOSIS TO THE ELUCIDATION OF CERTAIN PROBLEMS IN CONNEXION WITH THE DURATION OF IMMUNITY AND THE GEOGRAPHICAL DISTRIBUTION OF DISEASE.

BY A. E. WRIGHT, M.D. DUB.,
PROFESSOR OF PATHOLOGY, ARMY MEDICAL SCHOOL, NETLEY,
AND
SURGEON-CAPTAIN F. SMITH,
ARMY MEDICAL STAFF.

IT is notorious that every clinician in tropical and sub-tropical countries is constantly meeting cases of continued fever of which he finds it impossible to say whether they are cases of typhoid fever, of Malta fever, of malarial fever, or of some other (possibly as yet undescribed) variety of continued fever. In cases of this kind, and further in cases where it is desirable that a diagnosis should be arrived at early in the course of the disease, the prompt and accurate methods of diagnosis which medical research has recently placed at our disposal will be everywhere welcomed. Three of such methods of diagnosis are at present available. In the first place, the blood may be examined microscopically with a view to determining the presence or absence of pathogenic micro-organisms. This method is of particular utility in connexion with the determination of the presence or absence of the micro-organisms of malaria and of spirillum fever. In the second place, the excretions (and, in particular, the urine[1]) may be examined by appropriate cultivation methods with a view to determining the presence or absence of pathogenic micro-organisms. This method is applicable to typhoid fever. It is probably also applicable to Malta fever. Lastly, the method of serum diagnosis may be applied. By this method the blood of a patient who is suffering, or who has suffered, from a continued fever is tested in turn with any pathogenic micro-organisms that may be available, and in particular with the micro-organisms which are causally associated with typhoid fever and Malta fever. We have recently been applying this serum test to the diagnosis, and especially to the after-diagnosis, of tropical and sub-tropical continued fevers. Convalescents from these fevers come under observation in Netley in the persons of soldiers and others who are invalided home from military stations abroad.

METHODS.

Blood is readily obtained in sufficient quantities from the finger tip by puncturing the back of the finger near the nail. It is then drawn off into a pipette, such as is represented in Fig. 1. This pipette is converted into a blood capsule by sealing it in the flame at the points indicated in the figure by the letters *x x*. After twenty-four hours, or as soon as the blood has duly separated into serum and clot, the ends of the blood capsule are broken off and the separated serum is drawn off by a capillary pipette, as indicated in Fig. 2. The amount of serum which is drawn off is indicated by placing a mark *y* on the outside of the capillary pipette. The serum is then blown out into a watch glass and is diluted first fivefold by filling up the capillary pipette four times in succession with normal salt solution and by blowing this salt solution out into the serum in the watch glass. In this manner any desired dilutions are obtained. It is convenient to make 5-, 10-, 25-, 50-, and 100-fold dilutions of each sample of serum.

Having diluted the serum in this manner a small quantity of the diluted serum is allowed to run up into the sedimentation tube[2] represented in the diagram by Fig. 3. For the sake of clearness let it be supposed that diluted serum has been allowed to run up the tube to the point indicated by the letter *a* in Fig. 3. This point is now indicated on the outside of the sedimentation tube by a red mark. Having filled in the tube in this manner with the desired amount of diluted serum, the point of the capillary pipette is now turned upwards, so as to admit a bubble of air into the point of the capillary pipette. The diluted serum now occupies the position indicated in Fig. 3 by the space *c* to *d*, the bubble occupying the space between the letters *b* and *c*. Having thus introduced our bubble of air, which is to serve the purpose of an index, the end of the capillary pipette is immersed into a perfectly fresh emulsion made from a young culture of either typhoid or, as the case may be, Malta fever bacteria. The emulsion is allowed to run in until it reaches the point *a*. We have now introduced an equal quantity of diluted serum and of typhoid or Malta fever emulsion into our sedimentation tube. The next step is to mix the bacterial emulsion with our diluted serum. This is easily done by aspirating by means of the india-rubber tube T the contents of the capillary pipette two or three times in succession into the mixing chamber *z*. Having thus obtained an intimate mixture of an equal portion of the diluted serum and of the bacterial emulsion, we blow the contents of the tube down into the stem of the pipette, taking care not to blow it down too near the end of the pipette, and we seal the point of the pipette in the flame. We then label the capillary pipette 1 in 10, if we have mixed an equal volume of 5-fold diluted serum with a bacterial emulsion; 1 in 20, if we have employed a 10-fold diluted serum, and so on. We then put up a control tube of the bacterial emulsion

[1] The importance both from a diagnostic and a hygienic point of view of recognising the presence of typhoid bacilli in the urine was pointed out in a paper which was written by one of us in conjunction with Surgeon-Major Semple (THE LANCET, July 27th, 1895). The results which were arrived at in that paper have been recently confirmed and somewhat extended by Dr. P. Horton Smith (Royal Medical and Chirurgical Society, Feb. 7th, 1897).

[2] Mr. A. E. Dean, jun., 73, Hatton-garden, E.C., is, at my suggestion, making sero-sedimentation tubes of stout glass. Provision is made in these tubes for preventing the escape of the contents when the tubes are placed upright so as to allow of sedimentation.

Hosted by Google

mixed with normal serum or with salt solution, and finally we place the whole series of sedimentation tubes upright in an ordinary test-tube labelled with the name of the patient and the date. Figs. 4 and 5 represent such capillary pipettes after the lapse of twenty-four hours. In Fig. 4 the dark shading seen at *x* represents a pellet of either typhoid or Malta fever bacteria which have been immobilised and agglomerated by a serum from a person who is undergoing, or who has undergone, the specific fever which corresponds to the variety of bacteria which have been employed. Fig. 5 represents the control pipette which in the case of the eminently motile Malta fever or typhoid bacteria remains evenly turbid.

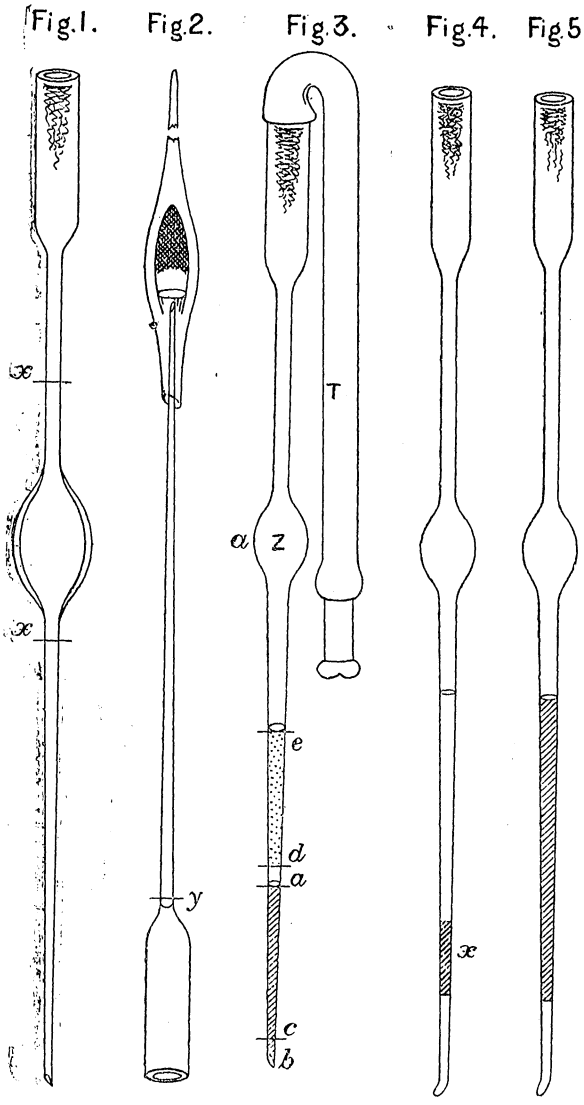

Fig. 1. Capillary pipette for drawing off blood from finger.
Fig. 2. Method of drawing off serum from blood capsule.
Fig. 3. Sedimentation tube filled in and ready for mixing.
Fig. 4. Sedimentation effect produced by specific serum. The pellet of agglomerated bacteria is seen at *x*; the supernatant fluid is clarified. Fig. 5. Control tube. No sediment is seen at bottom of tube; the fluid is not clarified.

Examples of the application of the method.—The following are typical examples of the application of the method of serum diagnosis to the differentiation of Malta fever from typhoid fever.

Example I.—Sergeant L——, of the Medical Staff Corps, arrived from Aldershot in October, 1896, having been detailed for duty at Netley. A few days after arrival at Netley the patient "reported sick" and was admitted to hospital with a recrudescence of a fever from which he had suffered some months before. His papers showed that this fever had been diagnosed to be typhoid fever. The patient's serum showed absolutely no reaction with the bacillus typhosus. His serum in 10-, 25-, 50-, 100-, and 200-fold dilutions showed a very marked reaction with the micrococcus Melitensis of Bruce. Inquiry into the patient's history revealed that when he went into hospital at Aldershot he had only recently returned from Gibraltar.

Example II.—Sergeant F——, of the Medical Staff Corps. The patient was admitted to hospital in Malta on Oct. 2nd, 1896. He died in hospital on Nov. 20th. Some of his symptoms, such as diarrhœa associated with blood in the stools, were suggestive of typhoid fever. The necropsy, however, showed only slight ulceration of the colon, and the absence of any implication of Peyer's patches. In the light of the facts, his case was diagnosed as having in all probability been a case of Malta fever.

A *stepson of the above*, aged nine years, contracted fever in Malta and died at the end of November after ten days' illness. The case was diagnosed as probably one of typhoid fever.

Another stepson, aged seven and a half years, contracted fever in Malta at the beginning of last December, and was immediately invalided home. Doubts were expressed in his papers as to whether the case was one of Malta fever or of typhoid fever. He is now quite convalescent. His serum gives an absolutely negative reaction with the micrococcus Melitensis, but gives a very marked effect in 10-, 25-, 50-, a 100-fold dilutions with the bacillus typhosus.

The *wife of Sergeant F——* contracted fever in Malta in the month of September. She was in bed for ten days. The serum gives an absolutely negative reaction with the bacillus typhosus. The serum, however, gives in 10-, 25-, and 50-fold—but not in 100-fold—dilutions a characteristic reaction with the micrococcus Melitensis.

A *child of Sergeant F——*, a girl aged three years, contracted fever in Malta in May, 1896 She suffered severely from fever till the end of September, 1896. She is now quite convalescent. Her serum gives absolutely no reaction with the bacillus typhosus, but the serum in 10-, 25-, 50-, 100-, and 200-fold dilutions gives very marked reaction with the micrococcus Melitensis.

It will be obvious how very difficult a clinical problem was presented by this last series of cases, and how very easily clinical problems of this kind can be re-solved by the employment of the method of serum diagnosis.[3]

Example III.—Private P—— (at present under treatment in Netley), invalided home from India for secondary syphilis. He has suffered for the last four months from a continuous but very irregular fever, which has some resemblance to to the typical curve of Malta fever. Examination of history discloses that the patient left England in March, 1892, for Gibraltar. He continued in good health until the autumn of that year, when he was attacked with continued fever, which, from its long duration (103 days in hospital) and from the fact that the patient was constipated throughout, may not unreasonably be assumed to have been Mediterranean fever. The patient left Gibraltar for India with his regiment in December, 1893, feeling perfectly well. In India he was noted as having suffered occasionally from attacks of fever. These attacks of fever were, however, not severe enough to require treatment in hospital. The patient began to suffer again from fever very soon after he was put under orders for home. His blood has been examined by us with negative results for malaria, and his urine has recently been examined by us with negative results both for the presence of typhoid and Malta fever micro-organisms. His serum exerts no influence upon the bacillus typhosus. It manifests, even in 1000-fold dilution, a very characteristic effect upon the micrococcus of Malta fever. It is obvious that the interpretation of the results of serum-diagnosis was here complicated by the fact that the patient has presumably suffered some four years ago from Malta fever, and that a reaction with the micrococcus of Malta fever might possibly have persisted for this period. In view, however, of the fact that the serum shows the specific reaction in such an enormous dilution, and, further, in view of the fact that four years have elapsed since he suffered from fever in Gibraltar, and lastly, in view of the fact that the patient is now suffering from pains in the joints, it seems to us practically certain that this patient is suffering from Malta fever.[4]

[3] Our experience with monkeys has shown us that the specific reaction to the micrococcus Melitensis is generally already present on the day after inoculation.

[4] The question of greatest clinical interest in connexion with this case is, of course, the question whether the patient was re-infected with Malta fever in India, or whether the attacks of fever from which he suffered at intervals in India were mere recrudescences of his original Malta fever. In view of the facts which one of us has, in conjunction

Hosted by Google

Having sufficiently illustrated this last point we may now subjoin in tabular form the results which we have obtained by the application of this method of serum diagnosis.

The results which are tabulated below were obtained by testing the reaction of the serum in the capillary sero-sedimentation pipettes which have been described and illustrated above.

*In the tables which are subjoined a voluminous sedimentation is indicated by the sign + ; a slighter but still perfectly characteristic sedimentation is indicated by the sign * ; a negative result is indicated by the sign* 0.

TABLE I.—*Cases Diagnosed as "Malta Fever" which showed Reaction on the Micrococcus Melitensis of Bruce.* [5]

No. of case.	Period elapsed since illness.		Degree in which serum was diluted.				
	Years.	Months.	1 in 10.	1 in 25.	1 in 50.	1 in 100.	1 in 200.
1†	—	5	*	*	*	0	0
2‡	—	6	+	+	+	—	—
3	—	6	+	+	+	+	+
4	—	8	+	+	+	+	+
5	1	8	+	+	+	+	+
6‖	1	9	+	+	+	+	+
7	3	—	+	*	*	0	0
8§	Now ill.		+	+	+	+	+

† Said to have been a very slight attack.
‡ Higher dilutions not tried.
‖ Marked effect in this case up to 1 in 300.
§ Gives a positive reaction up to, but not above, a 1000-fold dilution.

TABLE II.—*Cases diagnosed "Typhoid Fever" which showed Reaction on Typhoid Bacillus.*

No. of case.	Period elapsed since illness.		Degree in which the Serum was diluted.				
	Years.	Months	1 in 10.	1 in 25.	1 in 50.	1 in 100.	1 in 200.
1	—	5	+	+	*	0	0
2	—	6	*	*	0	0	0
3	—	6	+	+	+	+	+
4†	—	6	+	+	+	—	—
5	—	6	*	*	0	0	0
6	—	7	*	*	0	0	0

A not inconsiderable number of interesting facts are disclosed by a study of these tables. The following are perhaps the more important of these :—(1) Consideration of Table I. discloses the fact that the micrococcus Melitensis, which was discovered by Surgeon-Major D. Bruce, is in reality, as he asserted it to be, the true cause of Malta fever. Out of nine clinically more or less well-characterised cases which were examined by us, the eight which are tabulated here have shown a perfectly characteristic reaction to the micrococcus Melitensis. The only one of the nine cases which failed to react was that of a patient who had suffered from Malta fever five years previously to the date of our examination. We may not unreasonably surmise that the specific power of sedimenting the micro-organisms of Malta fever may, in this case, have passed away. (2) Consideration of Tables III. and V. discloses the fact that Malta fever is, as Bruce and others have long surmised, a disease which is not by any means confined to the Mediterranean basin. We have here what we take to be definite evidence of its existence in three stations in Northern India. We have, further, what we take to be probable evidence of its existence in Hong-Kong. (3) Table III. shows that a certain number of cases which are from their clinical symptoms diagnosed to be typhoid fever, are in reality cases of Malta fever. (4) Table IV. shows that a considerable number of cases which are from their clinical characters diagnosed to be typhoid are in all probability neither cases of typhoid fever nor cases of Malta fever. It is

with Surgeon-Major Semple, elicited on the survival of the micrococcus Melitensis in the spleen of monkeys who have perfectly recovered from Malta fever, both these interpretations appear to us to be equally admissible.

[5] We are deeply indebted to Surgeon-Captain L. Hughes for sending us a culture of this micro-organism. The culture which was sent to us was obtained in Malta from a fatal case of the disease.

Hosted by Google

possible that the fevers from which these particular patients suffered may have been malarious in character. It is also possible that these fevers may have belonged to some as yet undefined category of continued fever. What is important for us to note is the fact that any tropical fever which is unaccompanied by the presence of malaria parasites in the blood, and which can by the method of serum-diagnosis be shown to be neither typhoid fever nor Malta fever, is a fever which might very profitably be made the subject of bacteriological investigation. (5) Tables I. and II. show that the specific agglomerating and sedimenting power, which is acquired by the blood in cases of fever, persists in the blood for a considerable term of years. We have been able to demonstrate its existence in the blood in the case of typhoid fever after no less a period than twelve years. Similarly, we have been able to demonstrate its persistence in the blood for at least three years after an attack of Malta fever.

These facts are of the greatest importance, if, as was urged in a paper on Typhoid Vaccination [6] which was written by one of us in conjunction with Surgeon-Major D. Semple, the sedimenting and agglomerating power of the blood is in reality a true index of the condition of immunity.

Duration of the immunity against cholera which is conferred by undergoing either an anti-cholera inoculation or an attack of actual cholera.—With a view of further elucidating this question of the association of the sedimenting power of the blood with immunity we have recently examined the blood of one convalescent from (supposed) cholera, and further the blood of five patients who had submitted themselves to Mr. Haffkine's cholera inoculations. The results of these blood examinations are of a certain amount of interest, even though their interpretation is a matter of considerable difficulty and even though they have no very close relation with the question of immunity against septicæmias, such as typhoid fever and Malta fever.

* Vaccinated in two operations. † Vaccinated in one operation only.

In conclusion we desire to advert to a possible application of the method of serum-diagnosis to the differentiation of the buboes which are due to syphilis or ordinary pyogenic micro-organisms, from the buboes which are due to the entrance of the plague bacillus into the body. Necessity for some such method of differentiation arises, first in connexion with the study of the geographical distribution of plague, and secondly in connexion with the early diagnosis of mild cases of plague. This question of the differential diagnosis of buboes seems to us to acquire a certain importance in view of the fact that one of us when Medical Officer of Health for Penang, had occasion to observe and to call attention to the increased number of non-venereal buboes which occurred in Penang very soon after the outbreak of the great epidemic of plague in Hong-Kong.

Netley.

[7] In view of the differences which exist between various varieties of cholera it is perhaps worth noting that the cholera with which we tested these bloods is a cholera which was kindly placed at our disposal by Professor Pfeiffer. It is a cholera which shows the perfectly characteristic agglomeration and sedimentation when it is treated with the serum of Pfeiffer's immunised goats.

ISOLATION HOSPITAL FOR BLANDFORD, DORSETSHIRE.—Lord Portman has promised £500 towards the erection of an isolation hospital for Blandford, and if necessary will also give the site.

REMARKS UPON VIRTUAL OR RELATIVE MITRAL STENOSIS.

BY H. D. ROLLESTON, M.D. CANTAB., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL, AND TO THE VICTORIA HOSPITAL FOR CHILDREN, CHELSEA;
AND
W. LEE DICKINSON, M.D. CANTAB., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO ST. GEORGE'S HOSPITAL, AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

THE object of this paper is to draw attention to an occasional state of the mitral valve in which there are all the anatomical characters of stenosis, but on so large a scale that stenosis does not actually exist. The segments are thickened and welded together, and perhaps depressed into the cavity of the ventricle so as to approach the form of a funnel. The passage, however, is absolutely as large as, or larger than, natural, though small in relation to the ventricle which is dilated. Clinically, the blowing murmur of mitral regurgitation is always present, and frequently also a more or less typical murmur of the kind called "presystolic." Upon first meeting with such a case post mortem the question naturally presents itself whether there had not been actual mitral stenosis, till, perhaps only at last, the valve became enlarged as the ventricle dilated. However, it is very improbable that a valve which has once attained an important degree of stenosis and rigidity can afterwards become uniformly enlarged. It is true we sometimes find that valves which obviously have been, and perhaps are still, stenosed have undergone a certain amount of widening from laceration of the segments or rupture of the chordæ tendineæ; but such lesions have generally been produced through the medium of ulceration, and although the ulceration was doubtless invited by strain it is not with such irregular deformities that we are dealing here. A more satisfactory explanation is that the valve, though naturally tending to stenosis, has been held open from the first by the dilatation of the ventricle. In all such cases the disease of the valve and the disease of the ventricle seem to have originated at or about the same time. Most of them are instances of adherent pericardium in young persons, a condition which, arising in the rheumatic pericarditis of childhood, is attended equally by dilatation of the ventricle and mitral endocarditis of that limited kind which, if free to pursue its natural course, would end in stenosis. In others there is aortic regurgitation, the dilatation of the ventricle resulting from which has evidently overtaken the mitral disease while the valve was yet pliant and extensile, even if the latter set in first. In one of our cases there was neither adherent pericardium nor aortic regurgitation, but the ventricle had been kept dilated by persistence of the same attack of rheumatism which caused the disease of the valve. Under such circumstances, where dilatation of the ventricle is the more acute and violent mischief, the state of the valve we are considering is clearly beneficial. The orifice being fully large does not directly obstruct the circulation in the lungs, while by tending to stenosis it moderates the mitral regurgitation which is always present in these cases and which is free in proportion as the valvular segments yield to the strain. It is preferable, therefore, to describe the condition as "relative" rather than "virtual" stenosis; the latter term would imply the effects as well as the resemblance of the actual thing. We append an abstract of three illustrative cases from among a dozen of the same kind of which we have taken clinical and post-mortem notes.

CASE 1.—The patient was a girl aged twenty years. She had been liable to palpitation for the last two years and œdema of the legs for six months. The impulse of the heart was extensive and turbulent. The apex was in the fifth left space far outside the nipple line. At the apex there was an early rough murmur, accompanied by a thrill, ending in a snap, and followed by a blowing systolic murmur. The patient died from pneumonia. At the necropsy the two layers of the pericardium were found to be completely united by old adhesions. The right auricle was dilated and the right ventricle hypertrophied. The tricuspid and pulmonary valves were healthy. The terminal branches of the pulmonary artery were atheromatous. The left auricle was greatly dilated and had partly compressed the left bronchus. The mitral orifice fairly admitted two fingers. The edges of the segments and the

Hosted by Google

chordæ tendineæ were thickened and the latter shortened, so that the valve appeared pulled down into the ventricle somewhat in the form of a funnel. The left ventricle was hypertrophied and greatly dilated. The myocardium and the aortic valves were healthy.

CASE 2.—The patient was a man aged twenty-nine years. He had had rheumatism twelve years before and œdema and dyspnœa for the last six months. He suffered from angina. At the apex of the heart a rumbling diastolic murmur and blowing systolic murmur were heard. There was a double murmur on the sternum. At the necropsy the pericardium was found to be normal. The heart weighed thirty-four ounces. The right side was small. The left auricle was thickened. The mitral orifice nearly admitted three fingers, but from the thickening and welding together of the cusps it appeared to have been at one time stenosed and subsequently opened out by the dilatation of the left ventricle. The chordæ tendineæ were thickened and some of those belonging to the anterior cusp were eroded. This cusp showed an incipient aneurysm. The left ventricle was greatly dilated and hypertrophied. The myocardium was fatty. The aortic valves were sclerosed and incompetent; there were a few vegetations.

CASE 3.—The patient was a woman aged twenty-seven years. She had suffered much from rheumatism of late years. She had had cardiac symptoms for the last five months. The apex of the heart was in the fifth left space, five inches from the middle line. There was a short "presystolic" and loud systolic mitral murmur. She died cyanosed, with thrombosis of the axillary vein. At the necropsy the pericardium was found to be normal. The heart weighed twenty ounces. The right auricle was dilated and the appendix thrombosed. The tricuspid orifice was dilated and the segments were thickened. The pulmonary artery was atheromatous and contained some thrombi. There were pulmonary apoplexies in both lungs. The left auricle was dilated and hypertrophied. The mitral orifice admitted two fingers, but gave the impression of having been smaller, the segments being greatly thickened and retracted into the ventricle by shortening of the chordæ tendineæ. The myocardium was swollen. The aortic valves were healthy.

A SUCCESSFUL CASE OF CÆSAREAN SECTION IN A COTTAGE.

BY SIDNEY A. BONTOR, M.D., M.S. DURH.

THE question of what should be done when a child cannot for any reason be delivered per vias naturales is a sufficiently difficult one for the practitioner in towns where specially skilled assistance is available and where special institutions exist for the treatment of such cases; but it is even more serious and difficult for the country medical man far removed from aids of this description and who must depend upon his own resources; and the following case, in which both mother and child were saved and which occurred in a country cottage under considerable difficulties—*e.g.*, a levy had to be made on the neighbours to obtain sufficient utensils, &c.—is offered as a contribution to the subject.

The patient was a woman aged thirty-four years. Labour commenced at the full term about noon on Dec. 4th, and the "waters broke" about 7 P.M. on that day; the pains were slight, and occurred at rather long intervals. She continued thus until the morning of Dec. 6th, when the cervix was found to be fully dilated, but the uterine contractions were exerting no expulsive force upon the fœtus; there was a considerable caput succedaneum. Chloroform was administered and the forceps applied, but although considerable force was exerted the child did not advance. The forceps were then removed and re-applied, but the result was as before; so further attempts at delivery in this manner were abandoned, and I consulted with my friends, Dr. King and Mr. McBride, as to the best method of procedure, and after considering the case from all points we decided to advise the Cæsarean section, and to this the husband consented after having the alternative methods explained to him. The patient being already under chloroform the necessary arrangements had to be rapidly made. We had a considerable quantity of water boiled and stored for use in clean jugs, and while I selected and boiled my instruments Dr. King prepared the patient by washing the thighs, abdomen, &c., with ether and soap and water, and then applying a compress wrung out of a 1 in 1000 solution of perchloride of mercury; he then passed a catheter and gave a vaginal injection of a similar solution and applied a like compress over the vaginal orifice. The operation was then performed, Dr. King assisting and Mr. McBride continuing the anæsthetic. An incision about five inches long was made in the linea alba from about one inch above the umbilicus to two inches above the pubes, the bleeding points secured, and the peritoneum opened throughout the length of the wound. The uterus being thus exposed, Dr. King pressed the edges of the abdominal opening firmly against the uterus without extruding it, but in such a manner that fluids from the uterus could not pass into the peritoneal cavity nor bowel escape from the abdomen. A short incision was then made through the uterine wall down to the membrane and extended upwards and downwards by scissors on the finger as director to about four and a half inches in length; the membranes were then divided and the child extracted. The placenta was easily removed and the uterus contracted well; as it did so Dr. King squeezed the abdominal wall against it so as to extrude it for facility of suturing, and at the same time, by keeping the edges of the abdominal opening pressed together behind it, fairly closed the abdominal cavity; the uterus was then lightly sponged with sublimate lotion and sutured with seven deep and five half deep sutures of silkworm gut, the edges of the wound being thus brought into excellent apposition; it was then once more sponged and returned into the abdominal cavity. The deep sutures were so inserted that while they embraced the whole thickness of the muscular wall they avoided the decidua, and were placed at sufficient distance from the edge of the wound to avoid cutting out. The peritoneal cavity was flushed with plain boiled water, and the wound closed with interrupted sutures of silkworm gut, dusted with boracic acid, and dressed with cyanide gauze, covered with sal-alembroth wool, and kept in position by strapping. No drainage tube was used. The patient had some slight pain that night, for which an injection of a quarter of a grain of morphia was given, but beyond this there is little to add. Both mother and child made excellent progress, and there was not a single unfavourable symptom; the lochia passed freely, and were not excessive; the temperature did not rise above 99·4°; the pulse was good, and the tongue moist and clean throughout; the wound was dressed on the sixth day, and was found completely healed. The patient was nursed by the ordinary monthly nurse, who had never seen a surgical operation before.

Great Berkhamsted.

A CASE OF TRAUMATIC INTRA-THORACIC RUPTURE OF THE TRACHEA WITHOUT FRACTURE OF THE CHEST WALL.

BY SURGEON-LIEUTENANT CLAYTON A. LANE, M.D. LOND., I.M.S.,
LATE HOUSE SURGEON TO ST. MARY'S HOSPITAL.

A RAILWAY-VAN GUARD, aged fourteen years, was brought to St. Mary's Hospital on May 4th, 1895, having twenty minutes earlier had his chest crushed between a heavy van and an iron-edged platform. So far as was known his head was not injured. When seen he lay crying out wildly, but answering no questions; he threw his right arm and leg about freely and repeatedly, but did not move his left limbs at all; his face he distorted by grimaces and both sides of it moved equally. There were no signs of injury about the head or on the chest. No broken ribs were discovered, and though the chest was tender to the touch its movement and resonance were normal. Loud rhonchi were heard all over both lungs, rendering completely inaudible the heart sounds. The pulse was feeble; the abdominal organs were normal. The patient had been perfectly well, without cough, up to the time of the accident. At midnight he was very restless, took but little notice of his surroundings, and was somewhat blue with orthopnœa. There was more movement of the left limbs. He had
